VAN DER LEE, J. Het brood en enkele andere producten van de bakkerij en de bloemverwerkende industrie. [**Bread and some other products of the baking and milling industries.**] *Voeding*, 1955, **16**, 894–900. [Stat. Maalderij, Bakkerij, Wageningen.]

A chapter for Jansen's textbook on nutrition (see Abst. 3588, Vol. 24).

1580

ANDERSON, D. M. W. and GREENWOOD, C. T. **An investigation of the polysaccharide content of oats, *Avena sativa* L.** *J. Sci. Food Agric.*, 1955, **6**, 587–592. [Dept. Chem., Univ. Edinburgh.]

Oat kernels were defatted and successively extracted with cold and hot water followed by cold and hot alkali. The resulting extracts were further fractionated by centrifuging and analysed for sugars, ash, protein and unhydrolysable material. Fructose was found entirely in the cold-water extract; glucose, galactose, arabinose and xylose were present in nearly all the fractions. Potentiometric iodine titrations showed that the unfractionated starch contained 26·0 per cent. amylose. From this and the results of oxidation of the starch with periodate it was calculated that the amylopectin contained on the average 20·3 glucose units per unit chain. Protein impurities interfered with the periodate oxidation.

Roots

1582

CASTLE, M. E. **The effect of winter weather on the composition of fodder-beet left in the ground.** *J. Sci. Food Agric.*, 1955, **6**, 579–581. [Dept. Animal Husb., Vet. Fac., Univ. Liverpool.]

Sample plants from a fodder beet crop left in the ground all winter were chemically analysed at intervals of about 14 days. The dry matter content of the roots stayed within the range 18·8 to 21·0 per cent. from October to the end of March and there was no evidence of deterioration of quality. At the end of April, the dry matter content had fallen to 17·8 per cent. and the small portions of roots above the ground were brown and soft. The proportion of tops to the total weight of roots and tops fell from 49·4 per cent. in October to 18·4 per cent. in March, later increasing. It is suggested that fodder beet may be left in the ground until required in order to reduce storage costs.—J. L. Corbett.

1583

CHENG, R. C. and HANNING, F. **Phenolic compounds in potato tissue.** *Food Res.*, 1955, **20**, 506–511. [Dept. Food Nutrit., Sch. Home Econ., Univ. Wisconsin, Madison.]

The content of tannins (tannin plus tyrosine) in the skin of 5 varieties of potato ranged from 1·13 to 2·27 mg. per g. and was higher than in the centre flesh, 0·54 to 0·79 mg. per g. There was no correlation between colour score and tannin content. From paper chromatograms chlorogenic acid was the only tannin-like compound present in detectable amounts in all 3 types of tissue, skin, discoloured areas and centre flesh; *l*-tyrosine was identified in discoloured areas and centre flesh and caffeic acid in skin extracts.—J. S. Thomson.

Legumes

1584

SINGH, H. D. and BANERJEE, S. **Studies on the effect of germination on the availability of iron in some common Indian pulses.** *Indian J. Med. Res.*, 1955, **43**, 497–500. [Dept. Physiol., Presidency Coll., Calcutta.]

Total, available, protein-free and protein-bound Fe were estimated in 8 different pulses before germination and after germination for 2 and 3 days. Available Fe before germination ranged from 0·86 to 4·40 mg. per 100 g. and after 3 days' germination from 1·19 to 6·18 mg. Total Fe ranged from 6·10 to 9·20 mg. Protein-free Fe before germination ranged from 0·94 to 2·31 mg. with a slight increase after germination.

J. S. Thomson.

1585

EHEART, J. F., YOUNG, R. W. and ALLISON, A. H. **Variety, type, year, and location effects on the chemical composition of peanuts.** *Food Res.*, 1955, **20,** 497–505. [Dept. Biochem., Virginia Agric. Exp. Stat., Blacksburg.]

To ascertain the effect of variety, type, year and location on the composition of groundnuts, 7 varieties of Virginia- and 5 of Spanish-type groundnuts were grown in an experiment over 5 years, in one year at 3 different locations. Estimations were made of protein, ether extract, vitamin B_1, riboflavin and nicotinic acid in the kernels and of protein in the hay. Variety had a greater influence on all constituents in the kernels than had year, but year had a marked effect on vitamin B_1 and riboflavin. Location had a greater effect on vitamin B_1, riboflavin and hay protein than variety, and neither had much effect on kernel protein or ether extract. Spanish-type groundnuts were higher in protein, but Virginia were higher in nicotinic acid and in the protein of the hay. Average values found for protein, riboflavin and nicotinic acid were higher than those quoted by FAO (see Vol. 24, p. 727).—J. S. Thomson.

NAISMITH, W. E. F. **Ultracentrifuge studies of the ammonium sulphate fractions of the protein from yellow lupin seed (*Lupinus luteus*).** *J. Sci. Food Agric.*, 1955, **6,** 721–724. [Imperial Chemical Industries, Ltd., Nobel Div., "Ardil" Fibre Factory, Dumfries.]

The protein extracted by 10 per cent. NaCl from yellow lupin seed meal was fractionated with $(NH_4)_2SO_4$. Examination in the ultracentrifuge at ionic strength 0·5 and *p*H 7·6 revealed 4 sedimentary components. Three of these with sedimentation constants of 11·7, 7·6 and 1·8 Svedburg units were obtained reasonably pure. The first dissociated reversibly and slowly when the ionic strength was reduced; the second associated reversibly and rapidly.

For results with blue lupin seed see Joubert, *Biochim. biophys. Acta*, 1955, **16,** 370.

ANET, E. F. L. J. and REYNOLDS, T. M. **Water-soluble constituents of fruit. 2. The separation of acids on anion-exchange resins: the isolation of *l*-quinic acid from apricots.**

ASH, A. S. F. and REYNOLDS, T. M. **3. An examination of the sugars and polyols of apricots, peaches, pears, and apples by paper chromatography.**

ANET, E. F. L. J. and REYNOLDS, T. M. **4. The organic acids in peaches.** *Austral. J. Chem.*, 1955, **8,** 267–275; 276–279; 280–284. [Div. Food Preservation, C.S.I.R.O., Homebush, N.S.W.]

For part 1 see Title 3377, Vol. 25.

2. The resins used were Amberlite IRA-400, Dowex 1-X4 and Dowex 2-X4, the acids being displaced by 0·1 *N* HCl. The order of emergence of 27 acids is given. The isolation of *l*-quinic, succinic, *l*-malic and citric acids from apricots is described. R_F values are recorded for 30 acids in the solvent systems methyl ethyl ketone-cineole-aqueous formic acid (53 per cent.) (50 : 50 : 36) and ethanol (95 per cent.) - ammonia - water (80 : 5 : 15).

3. Xylose, fructose, glucose, sucrose, sorbitol, a cyclitol (probably *meso*-inositol) and one or more ketose oligosaccharides were detected in 80 per cent. ethanolic extracts of apricots, peaches, pears and apples. Pears were shown to contain galactose, which may be present also in some other fruits. The solvent mixtures used were ethyl acetate-pyridine-water (8 : 2 : 1), *n*-butanol-acetic acid-water (4 : 1 : 1) and phenol-water (4 : 1).

4. *l*-Quinic, *l*-malic and citric acids are the chief acids of the peach: a small amount of mucic acid was also detected. Galacturonic acid was present under certain ripening conditions.

JACQUIN, P. and TAVERNIER, J. Sur la teneur des jus de fruits en méthanol. [**Methanol content of fruit juices.**] *Bull. Soc. sci. Hyg. aliment*, 1955, **43,** 214–217. [Stat. Recherches Pomol., Rennes.]

Methanol, estimated by the method of Denigès in samples of apple, black-currant, gooseberry and tomato juice and fruit cocktail of French origin and orange, grapefruit, and pineapple juice from the United States was found to range from 45 mg. per litre for apple juice (mean of 3 samples) to 680 in a sample of sweetened black-currant juice; the American juices had less than the apple juice.

The methanol is thought to arise from demethylation of pectins by an enzyme, and it is suggested that fruit juice should be obtained from fruit not quite fully ripe and pasteurised as soon as possible.
W. M. Deans.

Other Types

1592
KREHL, W. A. and COWGILL, G. R. **Nutrient content of cane and beet sugar products.** *Food Res.*, 1955, **20,** 449–468. [Yale Nutrit. Lab., New Haven, Conn.]
Some 240 samples of cane and sugar beet products were analysed for their vitamin content and in some cases for inorganic constituents estimated spectroscopically. The products included blackstrap and high cane molasses, raw sugars, brown and soft sugars and cane juice. All contained small amounts of vitamins, insufficient to constitute them sources of these substances. The heating and lime treatment of cane or beet juice destroyed much of the vitamin B_1, riboflavin and pantothenic acid present.—J. S. Thomson.

1593
BUDZYŃSKA, J. Skład chemiczny polskiego oleju rzepakowego. [**Chemical composition of rapeseed oil.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6,** 229–233. Russian and English summaries.
Samples of Polish rapeseed oils showed the following ranges of percentage composition : lower fatty acids 0, higher saturated fatty acids 7·0 to 9·2, erucic acid 44·1 to 49·2, oleic acid 15·3 to 23·1, linoleic acid 13·3 to 18·0, linolenic acid 4·4 to 9·8. (From summary.)—J. S. Thomson.

1594
BISHOP, C. T. **Carbohydrates of sunflower heads.** *Canad. J. Chem.*, 1955, **33,** 1521–1529. [Nat. Res. Labs., Div. Appl. Biol., Ottawa.]
Stoikoff (*Mitt. Geb. Lebensmittel. Hyg.*, 1948, **39,** 292) suggested that sunflower heads, after removal of the seeds for oil, might serve as a source of pectin. At present in southern Manitoba they are ploughed in.
Shewfelt's method (*Thesis*, Oregon State Coll., 1952) of separating the pectin from polysaccharides by extraction of the heads, after removal of ash and extraction with ethanol-benzene, with a mixture of 0·25 per cent. ammonium oxalate and 0·25 per cent. oxalic acid solutions at 75° C., filtration and precipitation of the pectin with acidified ethanol was found to be effective, and it is suggested that it may prove useful in the study of other plant carbohydrates. Full details of the procedures and of subsequent work on the pectin and polysaccharide fractions are given.
Sunflower seed heads contained ash 11·95 and pigments and waxes extracted with 1 : 2 ethanol-benzene 12·7 per cent. After removal of these the percentage composition was lignin 12·3, pectin 27·5, alkali-soluble polysaccharides 8·2, α-cellulose 52. The pectin was 97 per cent. soluble in water. It was 37 per cent. esterified. In chemical properties it closely resembled pectin from other sources. Acid hydrolysis of the polysaccharides yielded D-xylose 59·3, D-glucose 23·5, D-galactose 16·2 per cent., traces of arabinose and rhamnose identified by chromatography, and 1·53 per cent. of an aldobiuronic acid, identified as 3-*O*-α-(D-glucopyruronosyl)-D-xylopyranose. There was evidence that the 3 main sugars were in 3 different polysaccharides, but attempts to separate these were unsuccessful.—W. M. Deans.

1595
COULSON, C. B. **Plant proteins. 5. Proteins and amino-acids of marine algae.** *J. Sci. Food Agric.*, 1955, **6,** 674–682. [Inst. Seaweed Res., Inveresk, Midlothian.]
For earlier parts see Abst. 270, Vol. 26.
Estimations were made of protein in extracts prepared in different ways and in the corresponding residues. There was interference with protein extraction, thought to be due to formation of a protein-alginate complex.
The amino-acid composition is tabulated for proteins prepared in bulk from *Rhodymenia palmata, Enteromorpha intestinalis, Laminaria cloustoni* and *Ascophyllum nodosum*. It is concluded that in general the proteins from these marine algae resemble, in amino-acid composition, those from fresh-water algae and higher plants, but differ from those of land plants in having more aspartic acid than glutamic acid.—D. Harvey.

Pasture, Hay and Silage

1601

NEHRING, K. and LAUBE, W. Untersuchungen über die Zusammensetzung der pflanzlichen Gerüstsubstanz in Grün- und Rauhfutterstoffen und ihren Einfluss auf die Verdaulichkeit dieser Futterstoffe. [**Composition of the components of supporting structures in green feeds and roughages and its effect on the digestibility of these feeds.**] *Arch. Tierernährung*, 1955, **5**, 177–215. [Inst. Landw. Versuchswesen, Rostock.]

The main supporting substances in plant tissues can be grouped as cellulose, pentosans and lignins. They were estimated separately, since it has been shown that losses occur when they are estimated together as crude fibre by the Weende method. Their digestibility was studied in 42 trials with 2 wethers; the green feeds and roughages were usually given alone, but those of poorest feeding value were given with some soya meal or meat-meal.

The crude fibre content of green feeds increased with advancing stage of growth, and the increase was most rapid in the early stages. The digestibility of the crude fibre decreased with advancing growth. The cellulose content also increased with growth and was usually close to the crude fibre content, though in straw, hay and green rye it was somewhat lower. All the crucifers, namely, marrowstem kale, mustard, winter rape and rape chaff, contained more cellulose than crude fibre. Digestibility of cellulose was usually higher than that of crude fibre, except when the digestibility of lignin was high. It fell with advancing growth.

The pentosan content of feeds increased with growth less than crude fibre or cellulose content, and more irregularly. Green rye, Italian ryegrass and straws had relatively high pentosan contents. There was no important difference in digestibility between cellulose and pentosans. In alfalfa and green rye, pentosans were more digestible than cellulose, which may be ascribed to the presence of a higher proportion of readily decomposable xylans. The lignin content rose regularly with advancing growth, and its digestibility was usually less than 10 per cent., though in a few green feeds such as rye the digestibility went up to 32 per cent., and in straws it lay between 10 and 20 per cent.

Correlation coefficients are given for the relations between crude fibre and supporting substances separately and together.

The N-free extract content was usually between 30 and 50 per cent. The content of residual carbohydrates, i.e. 100 — (ash + crude protein + crude fat + cellulose + pentosan + lignin), was much more variable and was related to species and stage of growth. It was the most easily digestible of all fractions, with a coefficient of digestibility usually exceeding 90. It is suggested that the conventional analysis of N- and fat-free substances and N-free extract is not sufficiently accurate for

modern needs, and that residual carbohydrate is a more meaningful fraction than N-free extract.

The effects of the supporting substances on the digestibility of crude fibre, cellulose, crude protein and organic matter are discussed and regression equations are given.

It is concluded that although study of crude fibre by the Weende method is still useful, more information can be obtained by study of the separate supporting substances.—D. Duncan.

1602

HOLMES, W. and MACLUSKY, D. S. **The intensive production of herbage for crop-drying. 6. A study of the effect of intensive nitrogen fertilizer treatment on species and strains of grass, grown alone and with white clover.** *J. Agric. Sci.*, 1955, **46,** 267–286. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

For previous parts see Abst. 3383, Vol. 25.

Results from a small-plot experiment lasting 5 years are presented. Increasing applications of fertiliser N to pure grass swards raised dry matter yields and crude protein yields and contents progressively. In grass and clover plots crude protein content and proportion of clover in the herbage decreased. Species varied in their response to N and in their compatability with clover. In absence of clover, cocksfoot gave the highest yields when N was applied, but it was surpassed by ryegrass and timothy when clover was present. The relative merits of fertiliser and clover N are discussed. Shading by grasses appeared to be the most important cause of suppression of clover when N was applied, and this interaction, and the grass-clover relationship, are considered.—J. L. Corbett.

1603

DENT, J. W. **Seasonal yield and composition of lucerne in relation to time of spring cutting.** *J. Brit. Grassland Soc.*, 1955, **10,** 330–340. [Nat. Inst. Agric. Botany, Cambridge.]

Cutting alfalfa in spring at the early-bud stage instead of at the early-flowering stage increased the number of cuts possible during the season from 3 to 4. Total dry matter yield was unaltered, but the quality of the first cut was very much improved, crude fibre being lower and crude protein higher.

J. L. Corbett.

1604

WEHRMANN, J. Mangan, Kupfer und Kobalt in Pflanzen and Böden schleswig-holsteinischer Weidegebiete. [**Manganese, copper and cobalt in plants and soils of pasture in Schleswig-Holstein.**] *Plant and Soil*, 1955, **6,** 61–83. [Inst. Pflanzenernähr. Bodenk., Univ. Kiel.]

Samples were collected from 56 permanent pastures in Schleswig-Holstein. The lowest mean contents of Mn, Cu and Co were in plants grown on brown earths, low moor, and low moor or podsols, respectively, but there were wide ranges of variation with botanical composition and stage of growth even on the same soil. There was little relation between soil total Mn and the Mn content of pasture plants but on the more acid soils plants often took up more Mn. Plants containing less than 5 p.p.m. Cu were found only on podsols and low moor, which soils also contained least Cu; there was no effect of *p*H. All pasture samples from podsol and low moor contained less than 0·04 p.p.m. Co on a dry matter basis, and no sample on brown earth or alluvial marsh from the west coast contained less than 0·044 p.p.m. More acid soils tended to have more available Co, but the relation was less clear than with Mn.—D. Duncan.

1605

GARCIA-RIVERA, J. and MORRIS, M. P. **Oxalate content of tropical forage grasses.** *Science*, 1955, **122,** 1089–1090. [Federal Exp. Stat., U.S. Dept. Agric., Mayaguez, Puerto Rico.]

The oxalic acid content of 24 tropical grasses ranged from 0·02 to 2·57 per cent. of the dry weight, average 0·8. Three species of *Panicum* and 2 of *Pennisetum* had more than 1·6 per cent.

1606

DE WITT, J. B. and DERBY, J. V. (Jr.) **Changes in nutritive value of browse plants following forest fires.** *J. Wildlife Management*, 1955, **19,** 65–70. [U.S. Fish and Wildlife Serv., Laurel, Md.]

The effect of controlled burning and forest fires on the proximate composition of the leaves and young twigs of 4 plants commonly browsed by deer were examined. The experimental area was subjected to controlled burning in 1947, and was swept by fire in 1950. Periodical samples taken monthly from May to October from 1947 to 1952 and control samples from untouched areas and similar plants were analysed. Controlled burning resulted in increased protein in red maple (*Acer rubrum*), flowering dogwood (*Cornus florida*) and roundleaf greenbrier (*Surilax rotundifolia*), but white oak (*Quercus alba*) was not significantly affected. The effects were not carried over to the second year. The more severe fire caused significant increases of protein in all species, and the effect was still apparent after 2 years.—T. D. Bell.

1609

NEWMAN, R. J. **Molybdenum deficiency in Central Highlands and Upper Goulburn Regions, and adjoining districts.** *J. Dept. Agric., Victoria*, 1955, **53**, 451–463.

On acid soils of granite or basalt origin or Ordovician or Silurian sediments over more than 2 million acres in Central Highlands, Upper Goulburn and neighbouring districts the natural pasture is of low value. Vigorous swards of subterranean clover can be established after dressing with superphosphate and 2 oz. of a Mo salt per acre, with some lime on the more acid soils, *p*H 5·0 to 5·5. Field trials are described.—D. Duncan.

1610

STRANG, J. **A pasture response to applications of sodium molybdate.** *J. Austral. Inst. Agric. Sci.*, 1955, **21**, 179–180. [Dept. Agric., Berry, N.S.W.]

The site was on iron podsolised soil, a sandy clay loam developed *in situ* from argillaceous sandstone. It had received since clearing of forest a single application of superphosphate and was growing summer grass (*Digitaria*) and Japanese millet. Replicate plots were dressed with all combinations of, per acre, sodium molybdate 2 oz., borax 5 lb., copper sulphate 7 lb. and magnesium sulphate 56 lb., with 5 cwt. superphosphate per acre. All were sown with pasture seeds mixture and lime.

The best green herbage yields were from plots given Mo. Each of the other substances increased the response to Mo, but not significantly.

AXELSSON, J. and KIVIMÄE, A. Försök med ensiliering av grönmajs under 1953–1954. [**Experiments in ensiling green maize in 1953–1954.**] *Kgl. Lantbruksakad. Tidskr.*, 1955, **94**, 119–124. English summary.

Three varieties of maize from the United States, Eagle Hill, KF and Wisconsin 335, were ensiled at 2 different stages of maturity in each of 2 successive years. Eagle Hill, the earliest variety, was in the milk stage and the others were more immature. Silage dry matter contained more crude fat, crude fibre and ash and less N-free extract and carotene than the corresponding dry matter of the crop. Protein and total dry matter were about the same.

Eagle Hill had more dry matter, more N-free extract and less crude fibre in the dry matter than the other varieties, both in the green crop and in the silage. It gave the best silage but was too immature to give a first-class silage and there was about 23 per cent. crude fibre in the silage dry matter. The loss of nutrients during ensiling of all varieties was moderate; only silage from the first cuts contained a small amount of butyric acid.—A. Hepburn.

SQUIBB, R. L., BRAHAM, J. E., GUZMAN, M. and SCRIMSHAW, N. S. **Blood serum total proteins, riboflavin, ascorbic acid, carotenoids and vitamin A of New Hampshire chickens infected with coryza, cholera or Newcastle disease.** *Poultry Sci.*, 1955, **34,** 1054–1058.

Blood samples were collected from 5 flocks of birds of both sexes and of different ages, which were affected with coryza. At each sampling, blood was collected also from comparable healthy birds. The pooled results showed that the infection caused a statistically significant rise of the total protein, and a decrease of ascorbic acid, total carotenoids and vitamin A, in the serum. There was no appreciable change in the serum riboflavin.

The effect of cholera on the serum constituents was similarly studied in 3 flocks, moderately or severely infected. In the serum of infected birds the total protein and ascorbic acid contents were significantly less than in the serum of normal birds. Serum amylase also was reduced.

The effect of Newcastle disease was studied in 6-week-old birds which were not infected, or were showing high mortality from the disease, or were survivors of an attack. The survivors showed typical signs of " crazy chick " disease. The total protein, vitamin A and total carotenoid contents of the serum were significantly decreased as the result of the infection. The ascorbic acid content was significantly increased, but riboflavin remained unaffected. In the birds showing signs of " crazy chick " disease, the total serum protein was higher than in normal birds.

It is suggested that the value of nutritional measures for controlling coryza and cholera in poultry should be investigated.

DUMM, M. E., LAKEN, B. and RALLI, E. P. **Factors influencing adrenal weight and adrenal cholesterol in rats following stress.** *J. Nutrition*, 1955, **56,** 517–531. [Dept. Med., Coll. Med., New York Univ.-Bellevue Med. Centre.]

Studies were made on 391 male and female rats given 7 diets containing 22 or 16 per cent. vitamin-free casein, sucrose, hydrogenated cottonseed oil, cod liver oil, salt mixture and vitamins E and K and those of the B group. The effect of greatly increasing the amount of calcium pantothenate and of adding 1000 mg. ascorbic acid per 102 g. diet was studied. After 4 weeks the animals were subjected to unilateral adrenalectomy alone or accompanied by denudation of the skin. The left adrenal gland which had been removed was weighed and analysed for cholesterol, and after an interval the right adrenal gland was removed and analysed ; results were compared and the responses of male and female rats were compared.

In rats given a high intake of pantothenate the increase in weight of the adrenal glands during the second week after both types of operation was greater than in rats given a normal intake of pantothenate. A high intake of ascorbic acid also was associated with a greater increase of

adrenal weight in the second week after unilateral adrenalectomy. The restoration of adrenal cholesterol, depleted after the operation, was slower in rats given a large amount of ascorbic acid than in rats not given an addition, but was not affected by a high intake of pantothenate. In rats having 16 per cent. of protein in the diet, adrenal cholesterol was lower 24 hr. after unilateral adrenalectomy than in rats having 22 per cent. Adrenal cholesterol recovered more slowly in female than in male rats having a normal intake of pantothenate and 22 per cent. protein. A greater increase of adrenal weight and a more prolonged depression of adrenal cholesterol occurred when skin denudation accompanied unilateral adrenalectomy than when it did not.—G. F. Garton.

EAGLE, H. **The minimum vitamin requirements of the L and HeLa cells in tissue culture, the production of specific vitamin deficiencies, and their cure.** *J. Exp. Med.*, 1955, **102,** 595–600. [Lab. Infect. Dis., Nat. Microbiol. Inst., Nat. Insts. Health, Bethesda, Md.]

Requirements of a mouse fibroblast (strain L) and a human carcinoma cell (strain HeLa) for choline, folic acid, nicotinamide, pantothenate, pyridoxal, riboflavin and vitamin B_1 were estimated with a vitamin-deficient culture medium. Vitamin deficiencies did not become apparent until cells had been grown for from 5 to 15 days, when multiplication ceased and cell changes occurred. All 7 vitamins were found to be essential for the tissues in concentrations of 10^{-7} to 10^{-8} g. per ml. culture. No requirement for biotin, inositol, tocopherol, vitamin A, D, or K or lipoic acid was demonstrated in the conditions of the experiments, but the possibility of requirements for further vitamins is considered to exist.

BARTH, K. and ZUCKER, H. Zur Verwendung von Holzkohle in der Geflügelfütterung unter besonderer Berücksichtigung einer möglichen Vitamin-Adsorption. [**Use of wood charcoal in poultry feeding with special reference to possible adsorption of vitamins.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 300–307. [Inst. Physiol. Ernährung Tiere, Univ. Munich.] English summary.

According to Almquist and Zander (Abst. 3387, Vol. 10) signs of vitamin deficiency may appear in chicks on a diet including wood charcoal. The present experiment with 8 groups of 20 male and 8 groups of 20 female day-old New Hampshire chicks, reared in batteries from eggs from a single hatchery, did not confirm that result. The pullet chicks had a basal diet of, per cent., wheat 37, barley 15, oats 10, bran 5, pollards 4, soya grits 20 and fishmeal 6, with minerals, and mixtures supplying, per kg. diet, vitamin A 4000 I.U., vitamin D_3 400 I.U., vitamin B_1 2 mg., riboflavin 2 mg., and procaine penicillin 5 mg. From the 7th day of life half the groups had the same diet except that 1 per cent. wheat was replaced by the same weight of wood charcoal. Feed and water were available all the time. The plan was the same for the cockerels, but their basal diet was a fattening diet of, per cent., wheat 7, maize 20, barley 20, oats 5, bran 5, pollards 4, soya grits 26, fishmeal 6 and dried skimmed milk 4, with minerals, and mixtures supplying, per kg. diet, vitamin A 7000 I.U., vitamin D_3 1000 I.U., vitamin B_1 2 mg., riboflavin 2 mg. and procaine penicillin 5 mg.

Groups with and without wood charcoal did not differ significantly in mean bodyweight after 4 or 8 weeks, or in mean intake of feed or total nutrients after 4 or 8 weeks, or in mean efficiency of feed utilisation, or in blood clotting time, or in the vitamin A content of the liver ascertained at the close of the experiment for 2 chicks from each group. It was concluded that if the feeding and rearing conditions are good the adsorbent properties of 1 per cent. wood charcoal are too slight to affect the growth of chicks.—W. M. Deans.

FANGAUF, R., KLEIN, F. W. and BARLÖWEN, G. v. Der Einfluss des Pressens und des Lagerns von Mischfutter auf die Wirksamkeit verschiedener Vitamin-Zusätze. [**Effect of pelleting and of storage of mixed feeds on the activity of vitamin additions.**] *Arch. Geflügelk.*, 1955, **19,** 239–246. [Lehr- u. Versuchsanst. Kleintierzucht, Kiel-Steenbek.] English summary.

A standard poultry mixture containing green alfalfa meal, dried yeast and a vitamin A and D supplement was used as a standard and 5 other

diets with additions of natural and synthetic vitamins were tested. All diets were tested as fresh or stored meal and as fresh or stored pellets, and the criterion of quality was the growth of chicks for 8 weeks. More was eaten when the feed was pelleted and birds given pellets had better weight gains than those given meal. There was no evidence that storage for 8 weeks decreased the value of any of the diets. Diets containing full supplements of synthetic vitamins gave growth and efficiency of use of feed comparable with those given by the standard diet. In comparison with a group without vitamin supplement all groups given vitamins A, D and B complex had a better growth rate and a lower mortality rate.

DE, N. K. **A fluorometric method for vitamin A assay.** *Indian J. Med. Res.*, 1955, **43,** 391–395. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Biological material was first saponified to ensure that any vitamin A present was in the alcohol form. The unsaponifiable fraction was extracted with light petroleum and the extract was washed and dried. Vitamin A was estimated in samples of the same extract fluorimetrically, spectrophotometrically and colorimetrically with the $SbCl_3$ test. In the fluorimetric method a 10-ml. portion was placed in a cuvette and illuminated with light at 365 mμ. The resulting fluorescence was measured in a Photovolt Multiple Photometer, Model 520 M, an extremely sensitive apparatus capable of reading light values down to 10^{-4} microlumen. The instrument was calibrated with pure vitamin A, and the linear relationship between fluorescence and concentration of vitamin A was good for the range from 1 to 18 I.U. Good agreement was obtained with the 3 methods; for instance, an extract of shark liver oil was found to contain 6200 I.U. per g. by the fluorimetric, 5700 by the spectrophotometric and 6000 by the colorimetric method. Estimation of vitamin A by the fluorimetric method in portions of from 1 to 2·5 ml. plasma and milk did not yield consistent results. The effect of vitamin D, carotene, cholesterol and vitamin E on the fluorimetric estimation of vitamin A was studied also. Ultraviolet irradiation of carotene produced a fluorescent material, but the product did not possess the property of vitamin A as judged colorimetrically and it did not cure eye lesions in rats deficient in vitamin A. It was destroyed by further irradiation.—I. M. Sharman.

CASTER, W. O. and MICKELSEN, O. **Serum vitamin A level: a critique of methods and significance.** *Amer. J. Clin. Nutrit.*, 1955, **3,** 409–417. [Nutrit. Chem. Lab., Nutrit. Branch, U.S. Pub. Health Serv., Washington, D.C.]

When vitamin A is estimated spectrophotometrically the total absorption at 328 mμ. is due not only to the vitamin A present but also to other substances. Two methods are available for estimating the true absorption due to the vitamin. In the chemical method of Bessey the total absorption is first measured and the extract is then irradiated with ultraviolet light to destroy vitamin A. The residual absorption is then estimated directly. The validity of this method depends on the assumptions that ultraviolet light converts vitamin A to products having no absorption at 328 mμ., that interfering substances originally present do not undergo appreciable change in their absorption at 328 mμ., and that ultraviolet light causes quantitative destruction of vitamin A. The second method, that of Morton and Stubbs, depends on a mathematical procedure in which the irrelevant absorption is assumed to be linear over a small range near 328 mμ. The total absorption is measured at 3 points near 328 mμ., and from the results obtained the absorption at 328 mμ. due to material other than vitamin A is estimated and subtracted from the total. Five specimens of serum were analysed by both methods, and the estimations were repeated with 4 or 5 samples of the same serum to increase precision. The agreement between the two methods was found to be poor, especially in samples containing little of the vitamin.

From a survey of the literature for studies of the vitamin A status of human subjects, it is concluded that the concentration of vitamin A in the serum is a characteristic of the individual rather than a reflection of the intake of vitamin A. From this conclusion and from the difficulties of estimating vitamin A, estimation of serum carotene is recommended as a measure of vitamin A status.

I. M. Sharman.

1632

ROGERS, A. R. **Tables for the rapid application of the Morton-Stubbs correction in vitamin-A assay.** *Analyst*, 1955, **80,** 903–906. [Anal. Dept., Allen and Hanburys, Ltd., Ware, Herts.]

Estimation of vitamin A according to the International Pharmacopoeia, the British Pharmacopoeia, and the United States Pharmacopeia is by spectrophotometric measurement with employment of the Morton Stubbs correction for irrelevant

absorption. The procedure requires measurement of extinction at the wavelength of maximum absorption of the pure vitamin and at two other wavelengths at which the extinction for the pure vitamin is exactly six-sevenths of the maximum. The British Pharmacopoeia, which specifies *cyclo*hexane as solvent, has rounded off the wavelengths for vitamin A acetate and alcohol, but has not made the corresponding adjustments in the coefficients that appear in the correction formula. On the assumption that the six-sevenths relationship holds, the formulae should read for vitamin A acetate

$$E_{corr.} = 7(E_{327\cdot5} - 0\cdot4\ E_{312\cdot5} - 0\cdot6\ E_{337\cdot5}),$$

and for vitamin A alcohol

$$E_{corr.} = 7(E_{326\cdot5} - 0\cdot417\ E_{312\cdot5} - 0\cdot583\ E_{336\cdot5}).$$

Such corrections are tedious and time-consuming. Simplifications are considered, and tables for accelerating the calculation of vitamin A potency by use of the figures given in the British and United States Pharmacopoeias are given. Values are recorded for the difference range 0·04 to 0·09, since differences outside those limits are seldom encountered with E values between 0·4 and 0·6, which is the optimum working range of most spectrophotometers. An example is given to clarify the arithmetical procedure.—I. M. Sharman.

1633

FELDHEIM, W. Zur Bestimmung des Vitamins A im Blut nach Bisaz. [**Estimation of vitamin A in blood by the method of Bisaz.**] *Schweiz. med. Wochenschr.*, 1955, **85,** 1242. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

The conclusion was reached that in the method of Bisaz (Abst. 234, Vol. 23) the precipitation of the proteins with alcohol carried down some of the vitamin A with it. It is, therefore, recommended that saponification with alcoholic potash should first take place, and that extraction should be with benzene instead of light petroleum. Estimations on 40 samples of serum gave results which were on the average 14 per cent. higher after saponification than before it.—E. M. Hume.

1634

BERGER, S. and DIETL, B. Metoda oznaczania β-karotenu w czekoladzie witaminizowanej. [**A method for estimating β-carotene in vitaminised chocolate.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6,** 181–184. Russian and English summaries.

The chocolate was mixed with water at 40° C. and the β-carotene was extracted in the cold with light petroleum. The recovery of β-carotene added to vitaminised chocolate was about 97·3 per cent. and that of total carotenoids about 94·1 per cent. The estimation with 2 concurrent samples took from 90 to 120 min. (From English summary.)

A. Hepburn.

1635

SWAIN, L. A. and IDLER, D. R. **Vitamin A instability.** *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1955, No. 103, 11–13. [Pacific Fish. Exp. Stat.]

Samples of oil obtained from 2 commercially produced halibut liver oil emulsions designated A and B, a mixture of 2 parts of A and 1 part of B designated C, and D, which was a refined preparation of C, were tested for the stability of vitamin A in them during 3 days' exposure to air at room temperature. The respective percentage loss was 6·6, 92·4, 93·0 and 96·7 when the spectrophotometric estimation was based on the whole oil, and 10·0, 93·2, 100 and 100 when estimation was by the Morton Stubbs method on the unsaponifiable fraction.

The iron content of oil A emulsion was 0·06 per cent. and was reduced to 0·007 per cent. by centrifuging; oil B contained 0·13 per cent., reduced to 0·012 by centrifuging. When 10 g. water was added to 1 g. oil A together with an emulsifying agent, 21·4 per cent. of the vitamin A was lost on standing at room temperature overnight. The loss was reduced to 4·9 per cent. by the addition of Versene, an iron-binding agent. The addition of 0·07 per cent. Fe as ferrous sulphate increased the loss to 73·6 per cent. and of 0·35 per cent. Fe to 82·9 per cent. The addition of Versene reduced the loss of vitamin A in the last instance to 5·9 per cent.

The addition of 0·04 per cent. butylated hydroxyanisole to oil A reduced the loss in a 3-day test from 9·5 per cent. to zero. The loss from oil B was reduced from 65·6 per cent. to 26·3 per cent. by 0·04 per cent. butylated hydroxyanisole, to 8·4 per cent. by 0·08 per cent. and to 5·3 per cent. by 0·20 per cent. Butylated hydroxytoluene was not quite as effective as the anisole derivative.

R. J. Ward.

HOLYER, N. F. and WEEDON, B. C. L. **Oxidative degradation of carotenoids.** *Chem. and Indust.*, 1955, No. 39, 1219. [Dept. Chem., Imp. Coll. Sci. Technol., London, S.W.7.]

On oxidation with permanganate, α- or β-ionone ring systems form αα-dimethylglutaric, αα-dimethylsuccinic and dimethylmalonic acids according to the position of oxygen functions in the end group attached to the polyene chain. When amounts of from 10 to 100 mg. carotenoid were oxidised the resulting di-acids were separated by paper chromatography and the individual acids were identified by comparison with mixed chromatograms of authentic samples. The best separation was obtained with ascending chromatograms on No. 1 Whatman paper with 20 μl. of alcoholic solutions of about 0·1 *M* of the di-acids. The irrigation solvent was xylene, phenol and 85 per

cent. formic acid. The papers were air-dried after from 12 to 18 hours' development and were sprayed with 0·05 per cent. alcoholic solution of bromocresol green and then with 3 per cent. aqueous solution of lead acetate. Yellow-green spots appeared on a blue background and were marked immediately because of rapid fading. Unsubstituted oxalic, malonic and succinic acids were separated satisfactorily by the chromatographic procedure and did not interfere with the dimethyl compounds. Geronic and *iso*geronic acids were readily separated from the other diacids but not from one another.—I. M. Sharman.

DIKSHIT, P. K. and RANGANATHAN, S. **Studies in carotene metabolism in mammals. 1. Experiments with goats. 2. Experiments with albino rats.** *Indian J. Med. Res.*, 1955, **43,** 481–487; 489–496. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

1. Goats fed on a diet of green grass, outer leaves of cabbage and Bengal gram excreted daily from 200 to 300 mg. carotene in the faeces without a trace being found in either milk or blood. After administration of massive doses of from 5000 to 14,000 μg. carotene by oral, subcutaneous or intravenous route, no trace of carotene could be found in the milk or blood. The vitamin A content of the milk was raised after carotene was given. When 10,000 μg. carotene was injected subcutaneously the vitamin A content of the milk after 24 hr. had risen to 88 from 60 I.U. per 100 ml. The same quantity of carotene injected intravenously raised the carotene content of the milk after 10 hr. to 102 I.U. from 68. The intravenous injection of 25,000 I.U. of a water-miscible preparation of vitamin A raised the vitamin A content of the blood from a trace to 167 I.U. per 100 ml. in 10 min. and that of the milk to 316 I.U. per 100 ml. from 54 after 10 hr. Studies *in vitro* in which carotene was incubated with goat's blood suggested that carotene was destroyed by oxidation and not by enzymic action. Investigation into the fate of carotene injected intravenously into goats showed that about 60 per cent. could be accounted for in the lungs within 10 min. of the injection, and none was found in the blood. Colostrum contained no carotene but was considerably richer in vitamin A than milk; 6 hr. after parturition it contained 816 I.U. per 100 ml.

2. When an intramuscular injection of 16,000 μg. carotene was given to a normal rat about 2 μg. only was found in the lungs 24 hr. later. When smaller quantities of carotene were injected into the heart considerable amounts of carotene were found in the lungs; for instance, when 925 μg. was given, 615 μg. was found in the lungs 5 min. later, and when 3040 μg. was given, 1989 μg. was found in the lungs after 10 min. When vitamin A was given in the same way, considerable quantities were found in the lungs whether the vitamin was given in oil solution or in a water-miscible form. In studies designed to examine the fate of carotene without its having to pass through the lungs before reaching the liver, injections of carotene were made into the spleen. There were discernible amounts of carotene in the lungs, 46 μg. being found after an injection of 300 μg. In experiments with rats deficient in vitamin A injections of carotene, ranging from 200 to 7000 μg., were given into the muscle, heart and spleen. Increase of bodyweight showed that carotene was physiologically active when given by any of those routes.—I. M. Sharman.

DANOWSKI, T. S., WIRTH, P., BLACK, M. H., BARTON, E. and BASTIANI, R. M. **Effect of vitamin A supplements on serum PBI level, and disposal of exogenous thyroxine.** *J. Clin. Endocrinol.*, 1955, **15,** 1262–1269. [Dept. Res. Med., Univ. Pittsburgh, Pa.]

Adolescent rats were fed for from 8 to 12 weeks on pellets which supplied them with 0, 2000, 10,000, 20,000 or 30,000 I.U. vitamin A acetate daily. Intakes of 10,000 I.U. or more of the vitamin, but not 2000 I.U., caused a significant decrease in the protein-bound iodine of the blood serum. This effect was not found in 2 healthy men and 2 healthy women who were given 500,000 I.U. vitamin A daily for 3 weeks, presumably because the dose was too small. In further studies rats were given 0·1 or 0·2 mg. thyroxine daily with or without 10,000 I.U. vitamin A. In 3 out of 4 experiments less protein-bound iodine was found in the groups which received 10,000 I.U. vitamin A than in the groups not given vitamin A. The difference was not statistically significant. In 4 human subjects the effect of thyroxine was not altered by vitamin A, 500,000 I.U. daily given by mouth, a dose per kg. bodyweight only one-fifth of that given to the rats. It is concluded that vitamin A affects the production and mobilisation of thyroxine, but not the rate of its disposal in the body.—T. Moore.

1643

MATTERSON, L. D., BUNNELL, R. H., STINSON, L. D., SINGSEN, E. P. and POTTER, L. M. **The effect of incorporating diphenyl-p-phenylenediamine (DPPD) into a ration containing various levels of vitamin A from fish oils.** *Poultry Sci.*, 1955, **34,** 1080–1084. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Univ. Connecticut.]

Groups of crossbred chicks were given for 8 weeks a semi-purified diet without vitamin A, supplemented per lb. with vitamin A from fish oil in amounts from 75 to 4800 I.U., and with or without diphenyl-*p*-phenylenediamine (DPPD). All the feed for the experiment was mixed beforehand and stored at 75° F. After 2, 4, and 8 weeks, 5 birds from each group were killed and the vitamin A content of the blood and liver was estimated. The maximum growth response in chicks given DPPD was obtained with 1635 I.U. vitamin A per lb. feed, and in those not given DPPD, with 2445 I.U. With supplements of vitamin A up to 1200 I.U. per lb., in the presence or absence of DPPD, the vitamin A content per g. liver was less at 8 weeks than at 4 weeks. It appeared, therefore, that more than 1200 I.U. per lb. feed, the National Research Council's recommended allowance, was required to obtain maximum growth and maintain liver reserves. With the amounts of vitamin A studied as supplement, the vitamin A content per g. liver at 8 weeks of age was from 2 to 5 times greater with DPPD than without. The vitamin A content of the plasma was higher also, though the increase was less than in the liver.—E. M. Cruickshank.

1644

MURRAY, T. K. and CAMPBELL, J. A. **The effect of aureomycin on the apparent utilization of vitamin A by the ovariectomized rat.** *J. Nutrition*, 1955, **57,** 89–99. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa.]

Young ovariectomised rats were given a diet deficient in vitamin A until their reserves were depleted as judged by the appearance of large numbers of cornified epithelial cells in the vagina. They received by mouth over a period of 2 days 25, 50 or 100 I.U. vitamin A. Aureomycin was given 2 days before dosage to half the animals and was supplied throughout the experiment. Vaginal smears were examined daily, and the number of days elapsing between the beginning of dosing with vitamin A when no cornified epithelial cells were present and their reappearance was recorded. The response results were calculated as days in relation to the logarithm of the dose. Aureomycin at the rate of 33 mg. per kg. diet had no effect, but with 66 mg. the apparent increase in utilisation of vitamin A ranged from 18·5 to 50·5 per cent. When the aureomycin was included in the diet from 2 days before dosing to only one day after it, it had no effect on the potency of vitamin A. When it was given from one day after dosing until the end of the test, its effect in increasing potency was of the same order as when given throughout the test, but given from 2 days after dosing it had no effect. The addition of 4 mg. α-tocopherol to the vitamin A did not affect the utilisation of vitamin A whether aureomycin was present or not. Vitamin B_{12} at the rate of 2·5 mg. per kg. diet did not behave like aureomycin, and it did not eliminate the effect of aureomycin.

MURRAY, T. K. and CAMPBELL, J. A. **Effect of aureomycin on liver storage of vitamin A, and on growth, depletion and survival time of rats.** *J. Nutrition*, 1955, **57**, 101–110. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa.]

Male and female rats were given a diet of starter mash which contained vitamin A. Aureomycin was given to half the animals at the rate of 66 mg. per kg. diet. After 28 days they were all killed and vitamin A was estimated in the liver. There was little difference between females given and not given aureomycin; the mean weight of the liver was, respectively, 7·2 and 6·9 g., and the mean content of vitamin A was 1590 and 1514 I.U. For males the corresponding values were 9·9 and 9·1 g., and 1412 and 1643 I.U. Both differences were significant absolutely but not in terms of vitamin A stored per g. food eaten.

In a second experiment rats of both sexes in 2 groups were given a diet without vitamin A and with or without aureomycin at the rate of 66 mg. per kg. diet. All the rats were given 50 I.U. vitamin A acetate 3 times a week. After 4 weeks vitamin A was estimated in the liver. For males there was no difference in the mean weight or vitamin A content of the liver. The livers of females given aureomycin were significantly smaller than those of females not given aureomycin, and weighed 4·24 compared with 4·76 g., but there was no significant difference in vitamin A content. Aureomycin had no influence on the rate of depletion measured by the vitamin A content of the kidney, liver or plasma, but age and weight at depletion were significantly increased by aureomycin in 2 out of 3 experiments. With a daily maintenance dose of 2 I.U. vitamin A, aureomycin significantly increased the mean weekly weight gain, but not with a daily dose of 1 I.U.

CAMP, A. A., CARTRITE, H. T., QUISENBERRY, J. H. and COUCH, J. R. **Supplementary vitamin A and choline in the diet of the growing chick.** *Poultry Sci.*, 1955, **34**, 1134–1138. [Texas Agric. Exp. Stat., Gonzales.]

Eight groups each of 112 chicks were given for 10 weeks a ration of yellow maize, milo, soya bean meal, fish solubles, dried whey, minerals and the necessary vitamins other than vitamin A, supplemented with 5 per cent. dehydrated alfalfa leaf meal, or 2·5 per cent. alfalfa and 2000 I.U. vitamin A per lb., and with or without choline. The vitamin A was in dry, stabilised form; the 2·5 per cent. alfalfa supplied 2300 I.U. vitamin A activity per lb. feed. The substitution of vitamin A for part of the alfalfa increased liveweight at 10 weeks of age to a highly significant extent and improved efficiency of feed conversion. The addition of choline to the ration containing 5 per cent. alfalfa also increased liveweight significantly, but there was no significant growth response when choline was added to the ration containing the vitamin A supplement. It is suggested that choline aids in the utilisation of carotene in alfalfa.

1647

HARMS, R. H., REID, B. L. and COUCH, J. R. **Storage of vitamin A in chick livers as a criterion of stability, availability, and dietary level.** *Poultry Sci.*, 1955, **34**, 1125–1133. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

Day-old chicks received for 4 or 10 weeks a basal diet without vitamin A or with, per lb., 4000 I.U. vitamin A from a fish oil or a stabilised vitamin A concentrate. The diets were freshly mixed every 5 weeks. Experiments were made at different seasons of the year.

Birds given stabilised vitamin A grew better and stored significantly more of the vitamin in the liver than birds given the vitamin in fish oil. The vitamin A content of the liver, particularly in the birds given fish oil, increased as the weather became cooler, probably because of increased feed consumption. The increase in liver storage in the birds given fish oil was much greater than in the birds given stabilised vitamin A, which was taken as evidence that in the hot weather appreciable destruction of the vitamin occurred in diets supplemented with fish oil and relatively little in diets containing stabilised vitamin A. In hot weather, chicks given diets which contained fish oil and which had been stored at 55° F. deposited more vitamin A in the liver than chicks given the same diets stored at the prevailing room temperature. In chicks given for 4 weeks amounts of vitamin A from 500 to 240,000 I.U. per lb. feed, the increase in vitamin A stored in the liver bore a linear relationship to the increase in dietary vitamin A. The percentage of the vitamin A ingested which was stored in the liver varied from 7 to 43; in general, increased intake resulted in increase in the percentage stored. In chicks which for 4 weeks were given graded amounts of vitamin A and then were deprived of the vitamin, survival time was directly related to the amount stored in the liver.

It is concluded that the amount of vitamin A deposited in the liver of chicks during a 4-week test may be used to evaluate the stability and availability of vitamin A supplements added to mixed feeds.—E. M. Cruickshank.

1648

DEADRICK, R. E., BIERI, J. G. and CARDENAS, R. R. (Jr.) **Effects of octachloronaphthalene**

on vitamin A metabolism in the rat. *J. Nutrition*, 1955, **57**, 287–295. [Dept. Biochem. Nutrit., Univ. Texas Med. Branch, Galveston.]

Rats whose stores of vitamin A had been partly depleted were given a diet deficient in vitamin A containing yeast and a daily supplement of 994 μg. vitamin A for 10 days, followed by the diet alone or with 0·05, 0·20 or 0·50 per cent. octachloronaphthalene incorporated in it. After 22 days for the 4 groups, respectively, the average vitamin A content of the liver and kidneys together was 37·6, 13·9, 8·4 and 4·6 μg. per g., and of the serum 59·6, 80·4, 73·0 and 97·2 μg. per 100 ml.

In a second experiment weanling rats were given a deficient diet containing yeast, alone or with 0·05 or 0·30 per cent. octachloronaphthalene. A single dose of 121·5 μg. carotene in oil was given by mouth 4 days before the rats were killed. The average respective vitamin A content of the liver and kidneys together was 5·6, 3·6 and 2·6 μg. per g. and of the serum 36·3, 36·9 and 30·4 μg. per 100 ml. The vitamin E content of the liver was 59·1, 50·1 and 40·6 μg. per g. for the respective groups, but the differences were not statistically significant. When the purified diet contained no yeast and was given with or without 0·03 per cent. octachloronaphthalene there was no significant change in the vitamin A or vitamin E content of the serum.

In a third experiment deficient rats were given the deficient diet containing yeast with or without supplements of 0·10 or 0·30 per cent. octachloronaphthalene. After 3 days half of each group was given orally 131 μg. carotene in oil and the other half an intravenous injection of 131 μg. carotene dispersed in water. In the groups receiving carotene intravenously there was no difference between those given and not given octachloronaphthalene in the amount of vitamin A formed or carotene recovered from the tissues. When the carotene was given orally the vitamin A content of the liver and kidneys together of the rats not given octachloronaphthalene was 9·7 μg.; with 0·01 per cent. octachloronaphthalene it was 6·4 μg., and with 0·03 per cent. octachloronaphthalene 6·2 μg. Faecal excretion of carotene could not be estimated because large quantities were present of a yellow pigment which could not be separated from carotene. The addition of 8 per cent. yeast to the purified diet prevented accumulation of fat in the liver of rats given octachloronaphthalene, but did not prevent enlargement of the liver.—R. J. Ward.

KAGAN, B. M. and KAISER, E. **Vitamin A metabolism in infection. Effect of sterile abscesses in the rat on serum and tissue vitamin A.** *J. Nutrition*, 1955, **57**, 277–286. [Dept. Paediat. Res., Kunstadter Labs. Paediat. Res., Michael Reese Hosp., Chicago, Ill.]

In rats receiving a diet containing 8 I.U. vitamin A per g., a subcutaneous or intramuscular injection of turpentine once a week produced sterile abscesses, and caused a pronounced reduction of vitamin A in the blood serum. There was also a slight decrease in the reserves of vitamin A in the liver, and an increase is claimed in the amount of vitamin excreted in the urine. The injections did not affect the ability of the rats to absorb vitamin A alcohol given by mouth. Injections of sweet almond oil also reduced vitamin A in the blood serum.—T. Moore.

1650

GREEN, B., LOW, J. S. and MORTON, R. A. **The effect of vitamin A deficiency on the cholesterol levels of the plasma and liver of the rat.** *Biochem. J.*, 1955, **61**, 447–453. [Dept. Biochem., Univ. Liverpool.]

Two groups of 20 weanling rats were given a stock diet for 40 days and then a synthetic vitamin-A-free diet. One group received a supplement of 12 I.U. vitamin A daily for 113 days and then 20 I.U.; the other group received 0·1 ml. arachis oil daily. Plasma cholesterol was estimated on 8 rats each day so that the 40 animals were examined every 5 days. Blood was withdrawn by cardiac puncture. Cholesterol was estimated by a modification of the method of Kenny (Abst. 1271, Vol. 23). At the end of the experiment vitamin A was estimated in the kidneys and cholesterol in the liver.

There was no significant difference between the 2 groups at the 1 per cent. level in the mean values for plasma cholesterol which over the period of the experiment ranged from 99·4 to 118·5 mg. per 100 ml. for the rats given vitamin A and from 94·4 to 119·5 for the deprived animals. There was also no significant difference between the 2 groups in the cholesterol content of the liver, the mean values for which were 18·57 mg. per liver for the non-deprived animals and 19·56 for the deprived, or 2·556 mg. per g. tissue for the non-deprived and 2·876 for the deprived.—R. J. Ward.

1651

BERN, H. A., ELIAS, J. J., PICKETT, P. B., POWERS, T. R. and HARKNESS, M. N. **The influence of vitamin A on the epidermis.** *Amer. J. Anat.*, 1955, **96**, 419–447. [Dept. Zool., Univ. California, Berkeley.]

Rats were fitted with pads to cover a shaved dorsal area, and were left untreated or given daily applications or injections of sesame oil or of a solution of vitamin A alcohol in sesame oil. The animals were killed after intervals of up to 60

days, and the area of skin from under the pad was examined histologically after staining by several different methods, and sometimes by electron microscopy. When applied to the skin vitamin A caused acanthosis, with doubling of the thickness of the skin. There was no evidence of differentiation into mucus-secreting cells, or of interference with the process of keratinisation. Sesame oil by itself caused only a slight thickening of the skin. Subcutaneous injections of the vitamin A solution or of the solvent oil did not cause thickening. Vitamin A resembled oestradiol in causing acanthosis when applied to the epidermis of the nipples of male guineapigs, and the thickening was about the same whether the vitamin and hormone were applied together or separately.—T. Moore.

1652

RAMALINGASWAMI, V., LEACH, E. H. and SRIRAMACHARI, S. **Ocular structure in vitamin A deficiency in the monkey.** *Quart. J. Exp. Physiol.*, 1955, **40,** 337–347. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Young growing monkeys, *Macacus sinicus*, were given a diet deficient in vitamin A, of polished rice, casein, arachis oil, minerals, and vitamins C, D and the B complex. Others were given adequate vitamin A. After from 3 to 4 months xerophthalmia appeared in 2 of the 3 monkeys not given vitamin A. Bitôt's spots were seen, and the eyelids were swollen. The concentration of vitamin A was much reduced in the plasma of these 2 deprived animals, but not in that of the third. When the monkeys were tested for their capacity for dark adaptation by threatening them silently with a white stick in a dark room, the 2 with a low value for plasma vitamin A responded only after from 35 to 45 min. in the dark. The third, and 2 given vitamin A, responded after from 4 to 6 min. By the end of the 4th month both the animals with a low plasma value for vitamin A had developed keratomalacia in one eye. Histological studies of the affected eyes revealed degeneration of the pigment epithelium of the retina and atrophy of the rods and cones. Descemet's endothelium was degenerated. In one animal damage to the retina was present without involvement of the cornea, which suggests that in man the incidence of damage to the retina through chronic deficiency of vitamin A may be much greater than would be assumed from the incidence of keratomalacia.—T. Moore.

GIROUD, A. and MARTINET, M. Malformations diverses du foetus de rat suivant les stades d'administration de vitamine A en excès. [**Foetal malformations in the rat after administration of excess of vitamin A.**] *C.R. Soc. Biol.*, 1955, **149,** 1088–1090.

Pregnant rats were given 60,000 I.U. daily of vitamin A for 3 days at different stages of gestation, and the effect on the foetuses was studied; the mothers were killed on the 21st day of pregnancy. When the vitamin was given from the 5th to the 7th day of pregnancy the usual effect was resorption of the foetuses. Of the few which survived, about 8 per cent. were anencephalic and some had cleft palate. Overdosage during days 8 to 10 caused anencephaly in 53 per cent. of the foetuses, and spina bifida, anophthalmia, microphthalmia and occasionally cleft palate. After treatment during days 11 to 13 cleft palate was found in 92 per cent. of the foetuses, and there were a few cataracts and "open eyes". Cleft palate was again the main lesion after treatment during days 14 to 16, but it occurred in only 49 per cent. of the foetuses, a few of which had cataracts. Finally, after treatment on days 18 to 20, cataract was the only abnormality found. The findings show clearly that the teratogenic action of the excess of vitamin A depends on the stage in development of the foetus at which the excess is given; the ill effects sometimes appeared to extend beyond the actual period of treatment.—T. Moore.

1655

WOLBACH, S. B., MADDOCK, C. L. and COHEN, J. **The hypervitaminosis-A syndrome in adrenalectomized rats; skeletal changes in weanling rats with and without cortisone.** *Arch. Pathol.*, 1955, **60,** 130–135. [Labs. Nutrit. Res., Child. Med. Centre, Boston, Mass.]

In rats which were given 1000 I.U. vitamin A palmitate per g. bodyweight daily, adrenalectomy accelerated the action of excess vitamin A on the skeleton. The essential nature of the lesions was, however, much the same with and without adrenalectomy. Survival time was prolonged by 50 mg. cortisone daily, but not by 1 mg.—T. Moore.

MAINARDI, B. Ricerche sperimentali su gli effetti delle dosi urto di vitamina A nei suini neonati. [**The effects of massive doses of vitamin A on newborn pigs.**] *Riv. Zootec.*, 1955, **28,** 326–330.

Baby pigs were given by mouth on the third day of life single massive doses of vitamin A ranging from 50,000 to 500,000 I.U. Growth was stimulated during the 8 weeks of the trial progressively more by doses up to 400,000 I.U. When

a dose of 1,000,000 I.U. was given growth was depressed, and signs of toxicity were produced by 10,000,000 I.U. Post-mortem examination of pigs dying within 4 days after getting the largest dose revealed kidney lesions, which are described.

GLEDHILL, R. H. and SMITH, S. B. **The effectiveness of different vitamin A sources for poultry.** *Poultry Sci.*, 1955, **34**, 942–948. [Rhode Island Agric. Exp. Stat., Kingston.]

Day-old chicks which received for 10 weeks a practical ration, supplemented with a commercial preparation of vitamin A in a dry form, gained more weight, used their feed more efficiently, and had a lower mortality rate, than when the vitamin was supplied as freshly processed fish liver oil or as provitamin A in alfalfa leaf meal. The storage of vitamin A in the whole liver of chicks receiving per lb. feed 1000 I.U. vitamin A in the dry form was 1396 I.U., compared with 985 and 680 I.U., respectively, for chicks receiving the same amount of supplementary vitamin A as fish oil or alfalfa. Egg production of pullets was higher with the dry preparation of vitamin A than with fish oil. Chicks hatched from the eggs of those pullets and maintained on a diet lacking vitamin A survived longer when the pullet's diet contained the dry forms of vitamin A than when it contained fish oil.

SAMPATH, S. R., ANANTAKRISHNAN, C. P. and SEN, K. C. **Studies on vitamin A in milk. 8. Vitamin A in market milk.** *Indian J. Dairy Sci.*, 1955, **8**, 129–134. [Indian Dairy Res. Inst., Bangalore.]

For Part 7 see Abst. 4349, Vol. 24.

Four hundred samples of milk, cow's, buffalo's and a mixture of the two, obtained commercially in Bangalore, were analysed for fat and vitamin A during the year 1953–54. The value for vitamin A, in I.U. per lb., ranged from 336 to 1025, 492 to 1536, and 449 to 1200 for cow's, buffalo's and mixed milk, respectively. The average monthly values for cow's milk varied from 582 in January to 806 in June, and for buffalo's milk from 745 in January to 1151 in September. Milk from centres in the municipal area had more vitamin A than others, which would be expected because such centres are known to take special care to provide adequate amounts of green fodder. The percentage of fat in the samples of cow's, buffalo's and mixed milk ranged, respectively, from 3·0 to 6·0, 4·4 to 8·6, and 3·2 to 6·2, with average values 4·2, 6·2 and 4·8.—I. M. Sharman.

1659

HIGASHI, H., HIRAO, S., YAMADA, J. and KIKUCHI, R. **The vitamin A content of *Heteroscymnus longus* Tanaka, a kind of deep sea shark.** *J. Vitaminol., Japan*, 1955, **1**, 200–207. [Sect. Marine Product Utilisation, Tokai Reg. Fish. Res. Lab., Tsukishima, Chuo-ku, Tokyo.]

The percentage of oil in the liver of 4 specimens of the shark *Heterocymnus longus* ranged from 62·5 to 80·5, and the vitamin A content of the liver oil from 2990 to 16,700 I.U. per g. The vitamin A content in I.U. per g. of other oils was for kidney from 516 to 25,500, pancreas 20,200, spleen 11,200 and egg 810. The oil content of the kidney, pancreas and spleen was about 2 per cent. and of the egg 35 per cent. The eyes contained from 114 to 118 I.U. vitamin A. The oil content of the flesh was from 15·8 to 23·1 per cent.; the oil of the common flesh contained from 505 to 1550 and that of the dark flesh from 318 to 856 I.U. per g. The vitamin A content of the flesh thus ranged from 9120 to 26,800 I.U. per 100 g., the highest vitamin A value for fish flesh ever known. The amount of vitamin A in the flesh was from 5 to 7 per cent. of that in the liver. The flesh oil contained about 10 per cent. of unsaponifiable matter. No squalene was detected in the flesh of any of the specimens.—R. J. Ward.

1660

FISHER, L. R., KON, S. K. and THOMPSON, S. Y. **Vitamin A and carotenoids in certain invertebrates. 2. Studies of seasonal variations in some marine crustacea. 3. Euphausiacea.** *J. Marine Biol. Assoc. U.K.*, 1954, **33**, 589–612; 1955, **34**, 81–100. [Nat. Inst. Res. Dairying, Univ. Reading.]

For Part 1 see Abst. 308, Vol. 24.

2, Fat, vitamin A and carotenoids were estimated in specimens of *Meganyctiphanes norvegica* and *Thysanoessa raschii* collected at about monthly intervals from Loch Fyne. Each monthly haul was separated into groups by length with 2-mm. intervals. Vitamin A was found in the eyes of both species, 66 to 100 per cent. of the total in *Meganyctiphanes norvegica*, and 65 to 98 per cent. in *Thysanoessa raschii*. In no group of either was β-carotene found in more than a minute trace. Astaxanthin or its esters was the only carotenoid found. In *M. norvegica* the eyes contained about 50 per cent. of the total in the animal, and in *Thysanoessa* the average was about 65 per cent. Chromatographic estimation showed a higher ratio of vitamin A ester to vitamin A alcohol in the eyes than in the bodies of both Euphausiacea. The concentration of vitamin A and astaxanthin was higher in the spring and autumn. Higher concentrations were found in larvae and in adults over 30 mm. long of *Meganyctiphanes*, and in larvae and in adults over 15 mm. of *Thysanoessa*, than in adults of 20 to 30 mm. and of 13 to 15 mm., respectively.

Similar estimations were made on specimens of the shrimps *Crangon allmani* and *C. vulgaris*, *Nephrops norvegicus* and the eyes of the lobster (*Homarus vulgaris*) which were collected at regular intervals for a year. No seasonal variation in the reserves of vitamin A and astaxanthin was found in the shrimps. The vitamin A content of the lobster eyes rose from 15 I.U. per g. in January to 20 in April and then fell to about 4 towards the end of the year. Carotenoids also reached their highest value, 85 μg. per g., in the spring and fell during the remainder of the year. The origin of the large reserves of vitamin A in the eyes of Crustacea is discussed and the possible role of astaxanthin as a precursor is considered.

3. Fat, carotenoids and vitamin A were estimated in 11 species of Euphausiacea. Groups of *Meganyctiphanes norvegica* from Loch Fyne and the Mediterranean had higher reserves of vitamin A, 11 to 29 I.U. per g., than those from open Atlantic waters, 7·4 to 11. From a total of 258 groups of this species a weighted average of 15 I.U. vitamin A per g. was deduced. Very high concentrations, over 100 I.U. per g., occurred in larvae. In *Thysanoessa raschii* concentrations of vitamin A were much more widely distributed, though half the groups examined had values between 10 and 45 I.U. per g. The weighted average for the whole series of 190 groups was 33 I.U. per g. In *Euphausia pacifica*, *Meganyctiphanes norvegica* and *Thysanoessa raschii* it was found that the vitamin A content of animals separated into eyes and bodies before preservation was higher than in animals left whole. The suggestion that a substance might be present in the bodies causing destruction of vitamin A is being further investigated. Vitamin A was found also in *Thysanoessa inermis*, *T. gregaria*, *T. spinifera*, *Euphausia superba*, *Nematoscelis difficilis*, *Stylocheiron maximum* and *S. elongatum*. In *E. superba* the concentration of vitamin A was less than in the other species containing vitamin A but was still higher than in other decapod Crustacea. No vitamin A was found in *Thysanopoda acutifrons*. In all the species examined astaxanthin or its esters was the only carotenoid detected. The role of euphausiids as the link conveying nutrient substances from detritus, phytoplankton and zooplankton to marine vertebrates is considered with particular reference to the conversion of carotenoids to vitamin A by them.

I. M. Sharman.

DODI, B. Variazioni di ordine genetico ed ambientale nel tenore in caroteni dei vegetali. **[Genetic and environmental variations in the carotene content of plants.]** *Riv. Zootec.*, 1955, **28**, 320–324. [Ist. Zootec. Gen., Fac. Agrar., Univ. Piacenza.]

Carotene was estimated by chromatography in 8 varieties of carrot (*Daucus carota*) each grown in 8 different centres with different types of soil. The method of estimation is described.

The average carotene content was 64·15 mg. per kg., but there was great variation between varieties and between centres. Important causes of difference between centres were time of sowing and degree of insect infestation. Information on the carotene content of feeds should include the minimum likely to be encountered, as well as the average.—T. D. Bell.

1663

SCHARRER, K. and RÄKER, K. Der Einfluss der Einsäuerung der Futtermittel auf deren Carotingehalt. **[Effect of ensiling feedingstuffs on their carotene content.]** *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 275–300. [Agrikulturchem. Inst., Justus Liebig Hochsch. (Univ.), Giessen.] English summary.

Lucerne, mustard, radish, sugar-beet leaves and other forage materials were ensiled in wooden or concrete silos each holding from 200 to 300 kg. A.I.V. solution, HCl, molasses, sugar, Amasil, Kofa salt, Glykosil salt and Glykosil solution were tested as preservatives. Silages were made also without addition. After 4 months the silages were examined for α- and β-carotenes, volatile acids, *p*H and protein degradation. Subjective observations were made on taste, smell, colour and structure. Quality was assessed on Flieg's scale.

The loss of carotene ranged from 3 to 88 per cent. There appeared to be no regular relationship between the type of preservative and the retention of carotene, or between silage quality and carotene content. Poor silage sometimes had a high carotene value. The α-carotene content sometimes appeared to increase, which may have been due to inclusion of isomers of β-carotene in the α-fraction.

The best silages were obtained with A.I.V. solution, molasses, sugar and Kofa salt, which were, on the average, about equally good for silage production. A.I.V. solution gave the most consistently good results. With sugar-beet leaves all the mixtures produced good silage.—V. H. Booth.

WIERZCHOWSKI, Z. Wpływ temperatury, tlenu i światła na zawartość karotenow w zielonkach roślin pastewnych w czasie suszenia. [**The influence of temperature, oxygen and light on the carotene content of green forages during drying.**] *Rocz. Nauk rol.* [*B*], 1955, **69**, 163–194. Russian and English summaries.

The green forages used were yellow lupins, alfalfa and bushy rye. The crops were dried in the field, in the shade under a roof, artificially in an air oven at from 50° to 60° C. with ventilation, in a vacuum oven at 50°, or in an air oven at from 105° to 200° C.

The percentage loss of carotene from alfalfa dried in the field was from 95 to 100, and in the shade 90. Artificial drying at high temperature showed a loss of from 6 to 69 per cent. according to the temperature and duration; loss was lowest at from 50° to 60° C. with ventilation, and highest at 105° C. Loss was high with very juicy material, and rapid drying helped to preserve the carotene. Vacuum drying gave a loss of only from 0·2 to 3 per cent. Lupin leaf meal, dried with ventilation, and stored in hermetically sealed glass containers for from 2½ to 4½ years, still contained from 16 to 77 mg. carotene per kg. Meals kept in dark glass containers at a low temperature for 16 months had a high proportion of the original carotene. (From summary.)—J. S. Thomson.

1665

BOOTH, V. H. **Preservation of carotene in dried green crops. An appraisal of the present standing of the problem of preventing loss during storage.** Association of Green Crop Driers, Cereal House, Mark Lane, London, E.C.3, 1955, pp. iii + 60. Price 8s. 6d.

The present state of knowledge about the problem of reducing loss of carotene during storage in dried grass and in lucerne and alfalfa meals is described in a monograph. There is an extensive review of published work, and new data based on original experiments are reported.

Loss of carotene can be prevented by exclusion of oxygen, but in practice exclusion is both difficult and costly. Storage in large tanks under an inert gas, as practised in the United States, gives excellent protection, but involves large capital costs. Grinding into meal causes heating, and loss of carotene during subsequent storage could be substantially reduced by cooling. Partial refrigeration, with the stacks of meal used as insulating material, might pay. Compression of meal into blocks gives a small amount of protection. When meal has to be stored in sacks or other packs permeable to oxygen, moisture content becomes important. A moisture content between 6 and 8 per cent. should be carefully maintained; managers of drying plants may not be aware that the product of their driers sometimes has less. Use of anti-oxidants can appreciably reduce loss of carotene, one of the most effective being 1 : 2-dihydro-6-ethoxy-2 : 2 : 4-trimethylquinoline. Oil as a vehicle for the anti-oxidant reduces dustiness of the meal, so that the total improvement may well warrant the cost of application. It is suggested that 150 g. anti-oxidant in 10 kg. vegetable oil should be applied per long ton (1000 kg.) meal. Such an amount corresponds with a final content of 150 p.p.m. of anti-oxidant and 1 per cent. of oil. Whether such anti-oxidants can be physiologically tolerated is still uncertain. The relative cost of the different protective schemes suggested is discussed. Control of moisture would be cheapest to operate, cooling would come second, particularly if combined with acceptance of coarser grinding, and when oil is applied to reduce dustiness the addition of anti-oxidant to it would come next. Partial refrigeration would be slightly more expensive. Barrier packing would be costliest of all.

The report recommends that dried green crop should be separated earlier than is usual at present into one of two categories according to its intended use as source of carotene or of protein. Only the former warrants protective treatment. Consideration should be given to the scheme "chop, compress, barrier-pack, store, grind at compounding plant and convey direct to mixer". Changes of machinery would be required, including replacement of mill by press, but the removal of dust and the reduction in transport costs and storage space of the denser material would contribute to justify the scheme.—I. M. Sharman.

VITAMIN D

1666

STROSS, P. S. and BREALEY, L. **The chemical estimation of calciferol in pharmacopoeial preparations.** *J. Pharm.*, 1955, **7**, 739–750. [British Drug Houses, Ltd., London, N.1.]

Estimation of vitamin D in Tablets of Calciferol B.P. and Solution of Calciferol B.P. were based on the antimony trichloride-acetyl chloride reaction of Nield *et al.* (Absts. 3363, Vol. 10 and 1028, Vol. 13), and included a chromatographic procedure of purification from decomposed calciferol. Results obtained by chemical tests were found to be in agreement with those of biological tests.

LYNESS, W. L. and QUACKENBUSH, F. W. **New color reaction for vitamins D.** *Anal. Chem.*, 1955, **27**, 1978–1980. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

The iodine and ethylene dichloride reagent was prepared in presence of mercuric *p*-chlorobenzoate, which enhanced the yellow colour given by vitamin D_2 and D_3 with the reagent. The yellow colour reached its greatest intensity in about 7 min. and then faded slowly; it had a very sharp maximum of spectral absorption at 450 mμ. The absorption of a number of samples of crystalline vitamin D_2 and vitamin D_3 was identical. Ergosterol, cholesterol, lumisterol, 7-dehydrocholesterol, stigmasterol and sitosterol gave no yellow colour, and the first 3 when tested did not interfere with the absorption of vitamin D. Vitamin A produced a weak violet colour with maximum absorption at 555 mμ. and with weak absorption at 450 mμ. Its presence caused some interference with the spectral absorption of vitamin D, and it is considered desirable to remove vitamin A from mixtures of it with vitamin D, which could be done by chromatography. The ethylene dichloride used sometimes needed purification with H_2SO_4 and silica gel. Other mercuric salts enhanced colour production, but none as much as the *p*-chlorobenzoate.—E. M. Hume.

1668

ROGERS, A. R. **The spectrophotometric determination of vitamin D in pharmaceutical preparations. 2. Tablets of calciferol B.P.** *J. Pharm.*, 1955, **7**, 731–738. [Anal. Dept., Allen and Hanburys, Ltd., London.]

A method is described for estimating vitamin D in tablets by extraction and direct spectrophotometric estimation at 265 mμ. in *cyclo*hexane, ethanol or light petroleum ($E\ ^{1\ per\ cent.}_{1\ cm.} = 470$) or at 267 m$\mu$. in ethylene dichloride ($E\ ^{1\ per\ cent.}_{1\ cm.} = 420$) and by spectrophotometric estimation at 500 mμ. of the colour developed in about 1 min. in the $SbCl_3$ reaction ($E\ ^{1\ per\ cent.}_{1\ cm.} = 2000$). A mixture of reagent and solvent in the blank cell instead of solvent alone was found to correct the rather high values previously found for the reagent blank. Ethylene dichloride was preferred as solvent since it is used in the preparation of the $SbCl_3$ reagent.—K. H. Coward.

HAVINGA, E., KOEVOET, A. L. and VERLOOP, A. **Studies on vitamin D and related compounds. 4. The pattern of the photochemical conversion of the provitamins D.** *Rec. Trav. chim. Pays-Bas*, 1955, **74**, 1230–1242. [Lab. Org. Chem., Univ. Leyden.]

For previous parts see Titles 363, Vol. 25; 329, Vol. 26.

Intermediate products of irradiation with ultraviolet light (265 to 280 mμ.) were obtained by exposing for a short time solutions of about equal amounts of radio-active 7-dehydrocholesterol-3-^{14}C and inactive lumisterol, or of radio-active ergosterol, obtained by growing yeast in a medium containing acetate-1-^{14}C, with inactive lumisterol and tachysterol. The unchanged provitamin D was removed by precipitation with digitonin. The irradiation products were separated by their different rates of reaction with maleic anhydride. From the specific radio-activities of the products it was concluded that lumisterol was not an intermediate product in the formation of vitamin D and that tachysterol probably was not either. The formation of another substance, previtamin D, was recognised, with the same spectral absorption at 265 to 280 mμ. as ergosterol, but with a relatively low extinction coefficient.—E. M. Hume.

PATRICK, H. and SCHWEITZER, G. K. **Usage of Ca^{45} in determination of vitamin D depletion and response time in chicks.** *Poultry Sci.*, 1955, **34**, 832–833. [Univ. Tennessee, Knoxville.]

Groups of day-old cockerels were given a basal rachitogenic diet alone or supplemented, per 100 g., with 200 I.U. vitamin D_3. Others were given 300 I.U. vitamin D_3 at one day of age and were maintained on the basal diet alone or supplemented, per 100 g., with 300 I.U. vitamin D_3. At the start of the experiment 8 chicks were given, by pipette, 20 μC. ^{45}Ca and 24 hr. later they were killed. The ^{45}Ca content of the right and left tibia together was estimated and expressed as a percentage of the 20 μC. administered. This percentage is termed degree of bone mineralisation. Eight chicks from each group were similarly given ^{45}Ca after 4, 7, 10, 14 and 18 days, and bone mineralisation was estimated 24 hr. later. In chicks on the basal ration alone the initial value for bone mineralisation was 13·4 per cent.; when they were depleted of vitamin D after 14 days, bone mineralisation was at its minimum, 7·2 per cent. In the birds given a single dose of 300 I.U. vitamin D_3 and maintained on the unsupplemented basal ration, some depletion was evident after 10 days and it was complete after about 18 days. In a second experiment depleted chicks were given 200 μC. ^{45}Ca at intervals up to 48 hr. after administration of 300 I.U. vitamin D_3; they were killed 24 hr. after administration of the isotope. An increase in bone mineralisation took place when the isotope was given 4 hr. after administration of vitamin D_3, and the maximum response was obtained when it was given after 24 hr. [It should

be noted that the degree of bone mineralisation was not estimated until 24 hr. after the administration of the isotope so that the first increase in bone mineralisation occurred 28 hr. after receiving vitamin D, and not 4 hr. as is shown in Table 2.]—E. M. Cruickshank.

1671

PATRICK, H. and SCHWEITZER, G. K. **A chick vitamin D assay method using radioactive calcium (Ca^{45}).** *Poultry Sci.*, 1955, **34,** 834–835. [Univ. Tennessee, Knoxville.]

Day-old cockerels were given a basal rachitogenic ration. After 6 days groups of 8 were given for 7 days supplements, per 100 g. diet, of from 5 to 200 I.U. vitamin D_3. Each chick then received, by pipette, 20 μC. ^{45}Ca. Twenty-four hours later the chicks were killed and bone mineralisation was estimated (see above Abst.). The results were compared with those obtained by the A.O.A.C. bone-ash method. The percentage of the amount of isotope given found in the tibias was no higher with 40 I.U. vitamin D_3 per 100 g. diet than with 20, showing that 20 I.U. sufficed to produce normal bone mineralisation. About 30 I.U. was required to produce a normal percentage of bone ash. A commercial sample of vitamin D concentrate was tested by the isotope method and the potency thus found was close to that guaranteed by the manufacturers.—E. M. Cruickshank.

MURRAY, T. K. and CAMPBELL, J. A. **A note on the effect of aureomycin on the response of the rat to vitamin D.** *Canad. J. Biochem. Physiol.*, 1955, **33,** 797–799. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa.]

Young rats were given the U.S. Pharmacopeia diet for the line test with addition of 5 per cent. brewer's yeast. In a number of tests, pairs of groups of from 8 to 10 rats were given a total dose of 0·75, 1·5 or 3 I.U. vitamin D over a period of 6 days. One of each pair of groups received in addition 66 mg. aureomycin per kg. diet 2 days before dosing began and until the end of the experiment. All the rats were killed 3 days after the last dose of vitamin D. The extent of calcification was measured by "usual bio-assay proceedures" (Bliss and György, *Vitamin Methods*, Vol. 2, Academy Press, Inc., 1951, New York), including the line test. The mean superiority in calcification for all the rats given aureomycin was 18 per cent., which was significant at $P = 0{\cdot}05$. The mean weight increase with aureomycin also was greater. The weight increase was not affected by the amount of vitamin D given, so that aureomycin presumably did not act by increasing the absorption of vitamin D.—E. M. Hume.

HORN, V. and EDER, H. Beeinflussung der Vit.-D_3-Wirkung durch Antibiotika beim Küken. **[Modification of the activity of vitamin D_3 for chicks by antibiotics.]** *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 249–252. [Vet. Physiol. Inst., Justus Liebig Hochsch., Giessen.]

Six groups of day-old White Leghorn cockerels were given the rachitogenic diet of Olsson and, by mouth, 0·025, 0·05 or 0·75 μg. vitamin D_3 daily. Three groups received in addition 25 mg. procaine penicillin per kg. diet. After 3 weeks the presence or absence of rickets was determined by measurement of the tarso-metatarsal distance. On the deficient diet alone, 0·025 μg. vitamin D_3 was not sufficient to protect any of the birds against rickets; 0·05 prevented rickets in 80 per cent., but when the diet contained penicillin, 0·075 μg. was required to give the same degree of protection.

DIKSHIT, P. K. **Effect of vitamin D on parathyroidectomized rats.** *Indian J. Med. Res.*, 1955, **43,** 679–684. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

Of 36 rats aged from 26 to 28 days, half had the parathyroid glands removed. The completeness of the operation was checked at autopsy. Five days later all the rats received a rachitogenic diet low in P, and were kept in a dark room. Each series was divided into 3 groups given 0·53 or 1·06 I.U. vitamin D daily or none. After 3 weeks all were killed. Bone ash was estimated in the femur, and the width of the epiphyseal cartilage in the tibia was measured. There was no significant difference referable to the removal of the parathyroid glands.

Of 2 series of rats, one had the parathyroid glands removed. They were all fed on a stock diet, and each series included 3 groups of 3 or 4 animals injected subcutaneously every other day for 50 days with 0·1 ml. groundnut oil containing 10,000 or 20,000 I.U. vitamin D or none. Percentage bone ash and adverse effect on weight gain were not significantly different in the 2 series.

It is concluded that the action of vitamin D is not mediated through the parathyroid glands.

PILEGGI, V. J., DE LUCA, H. F. and STEENBOCK, H. **The role of vitamin D and intestinal phytase in the prevention of rickets in rats on cereal diets.** *Arch. Biochem. Biophys.*, 1955, **58,** 194–204. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Male rats weighing from 60 to 75 g. were fed on a cereal diet of, per cent., yellow maize 76, wheat gluten 23, and NaCl 1 to which $CaCO_3$ was added, or on a semi-synthetic diet low in P to which Ca

was added as $CaCO_3$, inorganic P as an equimolar mixture of KH_2PO_4 and K_2HPO_4, and phytate P as sodium phytate. The rats were maintained on the diets for 21 days, and half of any group was given 75 I.U. vitamin D_2 every 3 days. Analyses were made of blood, bone and faeces.

With the cereal diet almost all the phytate was hydrolysed whether vitamin D was given or not. When 1 or 3 per cent. $CaCO_3$ was added the hydrolysis of phytate was much less, and addition of vitamin D only partly restored the amount hydrolysed.

With the cereal diet with or without 3 per cent. $CaCO_3$, and with the semi-synthetic diet, addition of vitamin D increased the phytase and alkaline phosphatase activity of the faeces and intestine. The hydrolysis of dietary phytate and absorption of P were correspondingly increased only when $CaCO_3$ was present. The relation between extent of enzyme activity and of phosphate hydrolysis was rough and not quantitative. Administration of vitamin D increased phytase and alkaline phosphatase in the faeces even though the diet contained no phytate.

By adjusting the amount of available P in the different diets it was shown that the increase of available P, brought about by vitamin D when rendering a phytate-containing diet high in Ca non-rachitogenic, was not sufficient by itself to account for the prevention of rickets. In rats having a rachitogenic cereal diet and not given vitamin D, compared with rats given vitamin D, the amount of inorganic P in the faeces was greater because of non-absorption, though the amount derived from hydrolysis of phytate was less.

It is concluded that " the antirachitic action of vitamin D with cereal diets is due primarily to an improved utilization of inorganic P ".

BAILIE, J. M. and IRVING, J. T. **Development and healing of rickets in intramembranous bone.** *Acta med. scand.*, 1955, **152**, *Suppl.* 306, 1–14. [Dept. Physiol., Med. Sch., Univ. Cape Town.]

The intramembranous bone studied was the maxillary incisal fundic alveolar bone adjacent to the formative end of the incisor tooth, where apposition and resorption are rapid during growth. Rats weighing from 50 to 80 g. were given the rachitogenic diet of Steenbock and Black, Ca : P ratio 5·6, with or without 1 per cent. lysine. They were killed at intervals of 3 or 4 days up to 28 days. Other material from rachitic rats, previously obtained, was studied also. To study the healing process, rats received one of the same two rachitogenic diets for 28 days, followed by a diet of stock biscuits for 4 days, or a single oral dose of 30 I.U. vitamin D with the same diet as before, or a modification of one of the same diets to make the ratio of Ca to P 1·86. After any of the changes rats were killed at intervals of from 6 hr. to 12 days. A portion of fundic bone was removed from the jaw and stained with haematoxylin and eosin or by the $AgNO_3$ method of Gomori (*Amer. J. Pathol.*, 1933, **9**, 253).

During the development of rickets the bone grew steadily wider. An osteoid margin appeared on the appositional side of the bone about the 10th day. It grew gradually wider while the calcified part of the bone remained fairly constant until the 21st day when it rapidly disappeared, and by the 28th day the bone was entirely osteoid. A primitive type of bone, with more matrix than cells, developed slowly from the appositional side for a time after the 10th day. Osteoclasts on the resorptive side of the bone became fewer but did not entirely disappear. It is considered that the osteoblasts could at first promote calcification of bone but progressively lost the power till by the 21st day they could form only osteoid.

The three means of healing tried all produced the same result but at different rates. Osteoid on the resorptive side of the bone began to show calcification within 2 days after vitamin D was given, and within from 12 to 24 hr. after the dietary changes. The first change was the calcification of osteoid. A layer of round cells on the resorptive surface, next the periodontal membrane, became re-established. They lined the calcifying bone between and around the osteoclasts, and gave the appearance of osteoblasts calcifying the osteoid tissue prior to its removal by osteoclasts, which decreased in number. As healing progressed the bone became narrower. After 3 or 4 days of healing calcification began on the appositional side, and continued till it met that from the resorptive side. The effect of a single dose of vitamin D began to lessen after 10 days, and by 12 days rachitic changes had begun again.

Rachitic changes and the healing process in the other bones ran parallel with the processes in the fundic bone.

The presence of lysine in the diet made no difference.

It is concluded that, in healing, calcification begins in the oldest osteoid on the resorptive side, and that osteoid is not resorbed until it has been calcified. In the soft tissues on the resorptive side there is a reserve of undifferentiated cells which can fuse to form osteoclasts or act as osteoblasts according to need. In rickets they lose their functions and differentiation, which revive when healing begins.—E. M. Hume.

ENGEL, C. **Vitamin D in milk.** *Nederlands Melk Zuiveltijdschr.*, 1955, **9,** 139–145. [Central Inst. Nutrit. Res. T.N.O., Utrecht.] Dutch summary.

Data from the literature are assembled and conclusions are drawn that the average vitamin D content per litre is 10 I.U. for human milk and 20 I.U. for cow's milk. Values are given for the requirement at different ages. Methods of augmenting the vitamin D content of milk are reviewed and discussed. The controversy about the vitamin D content of cow's milk irradiated with ultraviolet light by the process of Scholl, Scheer and Steinheil, as used at Frankfort am Main and Bremen, is briefly summarised, and it is concluded that the results giving the milk a negligible antirachitic potency, published by Wagner (*Milchwissenschaft*, 1953, **8,** 379), are not correct. The vitamin D content is considered to be between 160 and 200 I.U. per litre (Scheer, *Hessisches Ärzteblatt*, 1954, no. 7; Coates *et al.*, Abst. 1883, Vol. 25; Engel, Abst. 4813, Vol. 25), and the milk is accepted as effective in preventing and curing rickets.

VITAMIN E

1679

EGGITT, P. W. R. and NORRIS, F. W. **The chemical estimation of vitamin-E activity in cereal products. 3. The application of partition chromatography to the isolation of ε-tocopherol from bran and to the determination of the individual tocopherols of cereals.** *J. Sci. Food Agric.*, 1955, **6,** 689–696. [Dept. Appl. Biochem., Univ. Birmingham.]

For earlier parts see Absts. 2965, Vol. 24; 341, Vol. 26.

A partition column 1·4 cm. in diameter and 20 cm. long was prepared by loading Hyflo Super-cel, previously made hydrophobic by exposure to vapours of dimethyldichlorosilane, with 70 per cent. of liquid paraffin. The mobile phase was 75 per cent. ethanol equilibrated with paraffin. About 0·25 mg. of α-, γ- and δ-tocopherol was applied to the column and fractions of 3 ml. were collected mechanically. Estimations by the method of Emmerie and Engel were made directly on the 3-ml. fractions in the tubes in which they were collected. The peak for δ-tocopherol occurred with 51 ml. of eluate, and that for γ-tocopherol with 96 ml., but α-tocopherol was spread over 100 ml. When the solvent was changed to 80 per cent. ethanol after the 36th fraction, the α-homologue was eluted as a sharp band with 210 ml. Improved separation of δ- and γ-tocopherol was obtained by eluting first with 70 per cent. ethanol and then with 80 per cent. ethanol after the 70th fraction. The respective peaks were then with 81 ml. for δ-, 180 ml. for γ-, and 315 ml. for α-tocopherol. Chromatograms of the tocopherols from wheat germ, middlings and bran showed that the peak for ε-tocopherol coincided with that of δ-tocopherol, and that for β-tocopherol with that for γ-tocopherol. From the shape of the dimethyl curve of both bran and middlings it appeared that the recently discovered ζ-tocopherol, or 5 : 7-dimethyltocol, has an R_F value greater than that of β- or γ-tocopherol, which, it is suggested, may be due to the presence of a methyl group on each side of the hydroxyl group.

The percentage tocopherol pattern for wheat germ measured by this method was α 59, β 28 and ε 1·5, with 12 per cent. of reducing material retained on the column. For fine wheatfeed the percentages were α 28, β 24, ε 37 and 11 per cent. retained, for coarse bran α 11, β 20, ε 63 and 6 per cent. retained. The ultraviolet absorption spectrum of ε-tocopherol, isolated from bran in this way, had maxima and minima almost identical with those of β-tocopherol, and the absorption of nitroso-ε-tocopherol was almost identical with that of nitroso-β-tocopherol in both spectral position and amplitude.—R. J. Ward.

Myosin prepared from the muscles of rabbits which had been without vitamin E for only 2

weeks was abnormal in failing to dissolve completely in 0·1 *M* KCl. In solution it was less viscous than normal.—T. Moore.

1682

TALLAN, H. H. **Free amino acids of muscle of normal and of vitamin E-deficient rabbits.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 553–555. [Labs. Rockefeller Inst. Med. Res., New York.]

Ion-exchange chromatography was used to estimate the concentration of free amino-acids in muscle extracts of normal rabbits and dystrophic rabbits deprived of vitamin E. In the severely dystrophic animals the concentration of aspartic acid, glutamic acid, alanine, threonine, leucine, proline, urea, phosphoethanolamine and glycerophosphoethanolamine was much increased and that of glycine, 1-methylhistidine, carnosine and anserine was decreased. The concentration of glycine was low even in the earliest stage of dystrophy.—R. J. Ward.

1683

DINNING, J. S., SIME, J. T. and DAY, P. L. **The influence of vitamin E deficiency on the metabolism of sodium formate-C^{14} and glycine-1-C^{14} by the rabbit.** *J. Biol. Chem.*, 1955, **217,** 205–211. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

White New Zealand rabbits of about 600 g. weight were given a purified diet without vitamin E. Some received 4 mg. α-tocopheryl acetate per kg. bodyweight twice weekly. The deprived rabbits were selected for experiment when the ratio of creatine to creatinine in the urine had reached about 3 to 1 and when the rabbit had difficulty in righting itself when it was placed on its side. Deprived and non-deprived rabbits were injected intraperitoneally with 10 μC. of glycine-1-^{14}C or of sodium formate-^{14}C. The animals were killed 4 hr. later and certain organs and tissues were immediately frozen in a mixture of dry iec and acetone. The tissues were fractionated by the Schneider procedure (Title 2915, Vol. 15). One sample of the nucleic acid fraction was evaporated for counting and another was wet-ashed for estimation of phosphorus.

When glycine was injected, rats deprived of vitamin E incorporated less glycine into nucleic acids than non-deprived rats, and there was no increase in the amount of radio-activity incorporated. When sodium formate was injected the specific activities, in counts per min. per micromole P, of the nucleic acids of the skeletal muscle, bone marrow, small intestine, spleen and liver were for the deprived rabbits 41·9, 271·3, 82·7, 35·5 and 20·4, and for the non-deprived 5·3, 39·5, 18·0, 8·6 and 29·1.

In the protein the specific activity in counts per min. per mg. of the same tissues for rabbits injected with formate was for deprived rabbits 11·8, 103·2, 41·4, 42·9 and 38·5, and for non-deprived 1·9, 31·7, 19·0, 17·5 and 29·1. When the rabbits were injected with glycine the values for the deprived animals were 5·6, 44·1, 15·5, 27·5 and 19·9 and for the non-deprived 2·1, 89·3, 53·3, 57·7 and 44·4. When the nucleic acids of bone marrow and skeletal muscle were fractionated into ribonucleic acid and deoxyribonucleic acid, more radio-active formate was found to be incorporated into the deoxyribonucleic acid fraction. The specific activity of both acid-soluble and nucleic-acid purines after injection of formate was much higher in the deprived animals. Vitamin E deficiency reduced the incorporation of glycine into purines, slightly decreased the conversion of formate to CO_2 and increased the oxidation of glycine to CO_2.—R. J. Ward.

1684

LOEWI, G. **A lesion in the aorta of vitamin-E-deficient animals.** *J. Pathol. Bacteriol.*, 1955, **70,** 246–249. [Dunn Nutrit. Lab., Univ. Cambridge.]

In guineapigs and rabbits which had been deprived of vitamin E for from 7 to 10 months, areas of necrosis, calcification and fibrosis were found in the aorta. The abnormalities were mainly confined to the media; sub-endothelial fibrosis and nuclear palisading were also prominent. Histologically the lesions did not resemble atheroma even though necrosis was involved. No aortic lesion could be found in rats deprived of vitamin E for similar periods.—T. Moore.

1685

SLINGER, S. J., PEPPER, W. F. and ARTHUR, D. **Effect of phosphorus, vitamin E and environment on growth and the incidence of perosis in turkeys.** *Poultry Sci.*, 1955, **34,** 935–941. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Groups of Broad Breasted Bronze turkeys received, from hatching, diets containing different amounts of inorganic P with or without supplement of vitamin E. At 8 weeks of age each group was divided into two of which one was reared in a slatted sun-porch, the other on deep litter. For the next 16 weeks, all birds received a diet containing 0·5 per cent. inorganic P. The vitamin E supplement was continued to birds which previously received it. During the first 8 weeks diets containing 0·7 per cent. inorganic P gave better growth than those containing 0·5 per cent., but after 24 weeks the difference disappeared, and it is concluded that 0·5 per cent. inorganic P was sufficient in both starting and rearing diets for optimum growth and efficiency of feed utilisation. About

0·7 per cent. was required to prevent perosis. Supplements of vitamin E had no beneficial effect on growth up to 8 weeks of age, but increased the bodyweight of 24-week-old birds which had received 0·3 and 0·5 per cent. inorganic P during the starting period. The vitamin E supplement decreased the incidence and severity of perosis in all groups except those receiving 0·3 per cent. inorganic P in the starting ration. The birds reared on deep litter were in all respects superior to those reared in sun-porches.

BUNNELL, R. H., MATTERSON, L. D., SINGSEN, E. P., POTTER, L. M., KOZEFF, A. and JUNGHERR, E. L. **Studies on encephalomalacia in the chick. 3. The influence of feeding or injecting various tocopherols and other anti-oxidants on the incidence of encephalomalacia.**

SINGSEN, E. P., POTTER, L. M., MATTERSON, L. D., BUNNELL, R. H., KOZEFF, A. and JUNGHERR, E. L. **4. The influence of oil in fish meal, oils from various species of fish, and animal fats on the incidence of encephalomalacia.** *Poultry Sci.*, 1955, **34**, 1068–1075; 1075–1079. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Univ. Connecticut.]

3. Anti-oxidants were given to chicks deprived of vitamin E by intramuscular injection or in a basal diet supplemented with 2 per cent. of an oil containing vitamins A and D. The brains of chicks dying of encephalomalacia were examined histologically within an hour after death. Anti-oxidants found to be as effective in preventing encephalomalacia as N, N-diphenyl-*p*-phenylenediamine (DPPD) were 2 : 6-di-*tert*-butyl-4-methylphenol, dibutyl- and diamylhydroquinone, di-*sec*.-butyl-*p*-phenylenediamine and 1 : 2-dihydro-2 : 2 : 4-trimethyl-6-ethoxyquinoline. DPPD when injected gave complete protection, though no vitamin E could be detected in the blood. It was not as effective as vitamin E on an equimolar basis, but was nearly equivalent on a weight basis. When injected, α-tocopherol and γ-tocopherol gave almost complete protection, but δ-tocopherol was ineffective. The mode of action of anti-oxidants which prevent encephalomalacia is discussed, and it is suggested that they not only preserve vitamin E but also function as anti-oxidants *in vivo*.

4. Chicks hatched from the eggs of hens depleted of vitamin E for 2 months were given a basal diet containing, per lb., about 3 I.U. vitamin E from α-tocopherol. The diet was supplemented with 2 per cent. herring, red fish, cod liver or menhaden oil, or a feeding oil containing vitamins A and D, or a hydrogenated animal fat. Percentage mortality and incidence of encephalomalacia were directly related to the degree of unsaturation, and hence to the iodine number, of the oil. The hydrogenated fat, fat from meat scrap, or unstabilised yellow grease did not increase mortality from encephalomalacia. The addition of 2 per cent. lecithin to the diet containing the feeding oil considerably reduced the incidence, possibly because of the tocopherol content of the lecithin or its anti-oxidant properties. Oil added to the ration as fishmeal had the same effect as an equal amount of extracted oil. As little as from 0·5 to 1 per cent. of a highly unsaturated oil was sufficient to cause encephalomalacia in chicks deprived of vitamin E.—E. M. Cruickshank.

VITAMIN K

1688

MARCH, B. E., BIELY, J. and TOUCHBURN, S. P. **The composition of the breeder diet and blood clotting in dams and chicks.** *Poultry Sci.*, 1955, **34**, 1097–1100. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

The amount of vitamin K from dehydrated green feed given to hens kept in pens on litter did not influence the prothrombin time in the blood of the hens, but was reflected in the prothrombin time in the blood of the newly hatched chicks. When the breeding diet contained only 2·5 per cent. dehydrated green feed, the transfer of vitamin K to the chick appeared to be below the optimum but, since it varied somewhat from hatch to hatch, it is suggested that the vitamin K intake of the hens varied because of seasonal changes in temperature, which influenced synthesis of the vitamin by bacteria in the litter.

VITAMIN B COMPLEX: GENERAL

1689

KEVEI, E., KISZEL, M. and SIMEK, M. **Polarographic determination of the riboflavin and thiamin contents of foods. 1. Determination of riboflavin. 2. Determination of thiamin.** *Acta chim. hung.*, 1955, **6,** 345–363. [Inst. Res. Canning, Budapest.] Russian and German summaries.

1. Riboflavin was extracted by heating with 0·1 *N* HCl on a water-bath. The amount of acid required and the heating time varied for different foods according to the amount of riboflavin present. After acid extraction, incubation with takadiastase gave complete liberation of riboflavin. The extracts were centrifuged and cleared by precipitation of interfering substances with basic lead acetate. The riboflavin content of the solution could then be measured by polarography.

2. Free vitamin B_1 was extracted with HCl and alcohol. The vitamin was adsorbed on suitable charcoal, eluted successively with dilute HCl and 25 per cent. ethanol and measured directly in the polarograph. Bound vitamin B_1 was freed by incubation with takadiastase and subsequently extracted to give a value for total vitamin B_1.

For both riboflavin and vitamin B_1 it is claimed that more satisfactory results are given by polarographic than by fluorimetric methods.

DALGLIESH, C. E. **The relation between thiamine, biotin and tryptophan metabolism, studied in the rat.** *Biochem. J.*, 1955, **61,** 328–334. [Postgrad. Med. Sch., Ducane Rd., London, W.12.]

The effect was studied on metabolites in the urine of giving 1 mg. DL-tryptophan per g. bodyweight for 1 or 2 days to young rats having purified diets lacking vitamin B_1, or vitamin B_1 and pyridoxine, or biotin, or biotin and pyridoxine. After tryptophan non-deprived rats excreted small amounts of kynurenine, xanthurenic acid and anthranilic acid and its conjugates. Simple vitamin B_1 deficiency in severe stages prevented the excretion of any of these. Excretion after tryptophan of kynurenine, hydroxykynurenine, their conjugates and xanthurenic acid, characteristic of pyridoxine deficiency, was reduced in amount or ceased when vitamin B_1 was withdrawn as well as pyridoxine; if kynurenine was given instead of tryptophan at this stage the pattern of excretion typical of pyridoxine deficiency was restored. It is concluded that vitamin B_1 is concerned in the conversion of tryptophan to formylkynurenine. Lack of biotin alone or combined with lack of pyridoxine had no apparent effect on the pathways of tryptophan metabolism.—A. M. Copping.

BERNARDINI, A. Le modificazioni del contenuto in vitamine del complesso B da parte di tessuti di animali irradiati. 2. Le modificazioni della tiamina. [**Changes in the content of B complex vitamins in the tissues of animals treated with X-rays. 2. Changes in vitamin B_1.**] 3. Le modificazioni della niacina. [**3. Changes in nicotinic acid.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 295–297; 297–299. [Ist. Patol., Univ. Catania.]

With the same technique as was used for riboflavin (Abst. 390, Vol. 26), 4 groups of 7 rats were exposed once to X-rays, on the head only, on the thorax and abdomen, on the whole body, or not at all. Fifteen days later they were killed and vitamin B_1 and cocarboxylase were estimated in the liver, brain and muscle. In the muscle free vitamin B_1 increased after exposure, the increase being greatest when the whole body was exposed; the concentration of cocarboxylase was little affected. In the liver free vitamin B_1 and cocarboxylase decreased; the decrease was greatest when the thorax and abdomen were exposed. In the brain the free vitamin and cocarboxylase decreased, with the decrease greatest when the head was exposed.

3. With the same technique, in groups of 6 rats, the same parts of the body were exposed to X-rays. Fifteen days later nicotinic acid was estimated in the liver and muscle. In both tissues there was decrease in the content of nicotinic acid, which was greatest when the head was exposed, less with the whole body, and least with the thorax and abdomen.—E. M. Hume.

1692

DELORE, P. and BERRY, H. Carence alimentaire et recours à l'alcool. Recherches expérimentales. [**Dietary deficiency and recourse to alcohol. Experimental studies.**] *Presse méd.*, 1955, **63,** 1591–1592. [Lyons.]

When alcohol was available, rats on a diet deficient in the B vitamins took more of it than rats on a normal diet. Consumption of alcohol increased before signs of vitamin deficiency appeared.—L. Wills.

1693

LUCKEY, T. D., PLEASANTS, J. R., WAGNER, M., GORDON, H. A. and REYNIERS, J. A. **Some observations on vitamin metabolism in**

germ-free rats. *J. Nutrition*, 1955, **57**, 169–182. [Lobund Inst. Res. Life Sci., Univ. Notre Dame, Ind.]

With germ-free rats reared according to the method described by Orland *et al.* (Abst. 5037, Vol. 24) the requirement for biotin, folic acid, citrovorum factor, vitamin B_{12}, vitamin K and inositol was found to be like that of normally reared rats except that the presence of biotin in the diet seemed to be essential, and synthesis of folic acid and citrovorum factor did not take place without it. The amount of food eaten was measured and the shed hair, urine, faeces and wasted food were analysed for all vitamins of the B complex. Less riboflavin, nicotinic acid and biotin were found in body tissues and excreta than in the food consumed. The balance of pantothenic acid and vitamin B_{12} was even and the folic acid and citrovorum factor in the body exceeded the amount taken in. Severe biotin deficiency occurred in rats given no biotin, with loss of weight, loss of hair, dermatitis and skin ulcers. Germ-free male rats did not grow as rapidly as normal rats. Those born naturally and suckled by their dams grew better than rats taken by caesarean section and hand-fed to weaning.

A. M. Copping.

1694

BEZNÁK, A. B. L. and VAN ALPHEN, G. W. H. M. **Cardiac automatism and choline acetylation in rats on thiamine- and pantothenic-acid-deficient diets.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 867–883. [Dept. Physiol., Univ. Ottawa.]

Young male albino rats were given purified diets with a complete vitamin supplement, or without vitamin B_1 or pantothenic acid or both. Simultaneous deprivation of vitamin B_1 and pantothenic acid diminished the growth retardation and lessened the severity of the signs seen in rats deprived of vitamin B_1 only. When only pantothenic acid was lacking growth was similar to that of fully supplemented rats. Severe changes occurred in the electrocardiogram of all rats deprived of vitamin B_1 but no electrocardiographic abnormality occurred in those deprived of pantothenic acid only. No change was detected in the power to acetylate choline by extracts of heart muscle from rats deprived of vitamin B_1 or pantothenic acid or both. The results are discussed with reference to the literature, and further studies of a possible relationship between acetylcholine, cocarboxylase and disturbances of cardiac automatism are suggested.—A. M. Copping.

1695

JONES, J. D. and BAUMANN, C. A. **Relative effectiveness of antibiotics in rats given limiting B vitamins by mouth or by injection.** *J. Nutrition*, 1955, **57**, 61–71. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

The effect on growth of penicillin, aureomycin or streptomycin added in amounts of 25 mg. per kg. to a purified basal diet was studied in rats given a suboptimum dose, by mouth or injection, of vitamin B_1, riboflavin or pantothenic acid. The diet was adequate in all vitamins except that under investigation. Penicillin or aureomycin enhanced the effect of a limited amount of any of the 3 vitamins whether the vitamin was given by mouth or by injection, but the effect was in most experiments greater when the vitamin was given by mouth. Penicillamine and penicilloic acid had no effect on growth. Streptomycin did not increase the effect of a limited amount of vitamin given by mouth but did increase the effect when the vitamin was injected. The results are discussed with reference to many other observations, and it is considered that penicillin and aureomycin probably stimulate intestinal synthesis of vitamin B_1, riboflavin and pantothenic acid. The mode of action of streptomycin is discussed but is still unexplained.—A. M. Copping.

1696

HÜBNER, O. and LIEBSCHER, W. Der Vitamin-B-Komplex bei der Fütterung der Hühner. Versuche mit Fortafeed 2-49C. [**Vitamin B complex in poultry feeding. Experiments with Fortafeed 2-49C.**] *Arch. Geflügelk.*, 1955, **19**, 247–254. [Mitterndorf.] English summary.

The needs of poultry for vitamins of the B complex are reviewed and a table of the B vitamins in feedingstuffs is given. Studies were made with diets containing 3 per cent. food yeast or 0·03 per cent. of a supplement of riboflavin, pantothenic acid, nicotinic acid, choline chloride and folic acid (Fortafeed 2-49C) with 2·97 per cent. groundnut meal to give protein equivalent to that in yeast. During 10 weeks young birds grew equally well and used feed equally efficiently on both diets. In laying and hatching tests the synthetic supplement was as effective as the yeast and was cheaper.

A. M. Copping.

1697

MAYFIELD, H. L., ROEHM, R. R. and BEECKLER, A. F. **Riboflavin and thiamine content of eggs from New Hampshire and White Leghorn hens fed diets containing condensed fish or dried whale solubles.** *Poultry Sci.*, 1955, **34**, 1106–1111. [Dept. Home Econom. Res., Montana State Coll., Bozeman.]

Eggs were collected from New Hampshire and White Leghorn Hens on a basal diet with or without inclusion of condensed fish solubles or dried whale solubles. The diets contained, per g., 6·3 to 8·1 μg. riboflavin and 4·3 to 4·7 μg. vitamin B_1. The riboflavin content of the eggs was not

influenced by inclusion of fish or whale solubles but differed with breed. Eggs from Leghorn hens contained 220·7 μg. or 4·24 μg. per g. riboflavin; those from New Hampshire hens, 184 μg. or 3·57 μg. per g. The vitamin B_1 content of the eggs of the New Hampshire hens was much the same on all 3 diets, but the eggs of the Leghorn hens given fish or whale solubles contained 61·9 and 58·3 μg., respectively, compared with 51·1 μg. in eggs from Leghorns having the basal diet only. The eggs of the Leghorns had significantly more vitamin B_1 than those of the New Hampshires. The results showed the existence of a genetic difference between breeds in ability to use vitamin B_1 and possibly other components of the diet.

E. M. Cruickshank.

1698

CHITRE, R. G., DESAI, D. B. and RAUT, V. S. **The nutritive value of pure bred strains of cereals and pulses. 1. Thiamine, riboflavin and nicotinic-acid contents of 107 pure bred strains of cereals and pulses. 2. The effect of storage on thiamine, riboflavin and nicotinic acid in cereals and pulses.** *Indian J. Med. Res.*, 1955, **43**, 575–583; 585–589. [Indian Counc. Med. Res., Nutrit. Res. Unit, Seth G.S. Med. Coll., Parel, Bombay 12.]

1. Data are tabulated individually for the following numbers of samples of cereals and pulses: rice 51, jowar (*Sorghum vulgare*) 7, bajri (*Pennisetum typhoideum*) 2, ragi (*Eleusine coracana*) 1, tenai (*Setaria italica*) 5, wheat 13, red gram (*Cajanus indicus*) 10, green gram (*Phaseolus mungo*) 4, horse gram (*Dolichos biflorus*) 3, black gram (*Phaseolus roxburghii*) 7, Bengal gram (*Cicer arietinum*) 2 and lentil 2. Variations within species were wide and could not be definitely ascribed to environmental or genetic influences. Further investigation by pot culture in a greenhouse is recommended.

2. Pure strains of cereals and pulses were analysed before and after storage for 6 months in sealed bottles of amber glass or in gunny bags. With rice in bottles vitamin B_1 was unchanged and riboflavin increased; in gunny bags there was considerable loss of vitamin B_1 and the gain in riboflavin was larger; with either form of storage the nicotinic acid content was unchanged. In other cereals vitamin B_1 and nicotinic acid did not alter; their riboflavin content rose to the same extent in bottles and gunny bags. For pulses there was also no change in vitamin B_1 or nicotinic acid; riboflavin increased only during storage in gunny bags.—D. Harvey.

1699

FREY, K. J., HALL, H. H. and SHEKLETON, M. C. **Inheritance and heritability of protein, niacin, and riboflavin in oats.** *J. Agric. Food Chem.*, 1955, **3**, 946–948. [Dept. Agronom., Iowa State Coll., Ames.]

See Abst. 4428, Vol. 24.

From examination of 4 varieties of oats and the F_3 progenies from some of the crosses it was found that the contents of nicotinic acid and riboflavin were dominant in each of the crosses. In two crosses a high protein content was dominant; in another cross low protein was dominant. Heritability percentages for nicotinic acid and protein ranged from 83 to 93 and for riboflavin from 0 to 52.—A. Hepburn.

VITAMIN B_1 (ANEURIN, THIAMINE)

1700

MARTEN, G. **Quantitative separation of B vitamins by electrophoresis on agar plates.** *Nature*, 1955, **176**, 1064–1066. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

A brief preliminary note is given of a method for electrophoretic separation of vitamin B_1 and its pyrophosphate, monophosphate and disulphide on an agar plate. Cups cut in the agar held the test substances and the presence of vitamin B_1 was demonstrated with *Lactobacillus fermentum*, of the pyrimidine component with *Rhodotorula mucilaginosa* and of thiazole with *Phycomyces blakesleeanus*. It was possible also to use agar plates to assist separation of vitamins partly distributed by electrophoresis on paper. Full details of the method are to be published.—A. M. Copping.

1701

RIDYARD, H. N. **The determination of thiamine in vitamin concentrates containing Creta Praeparata.** *Analyst*, 1955, **80**, 834–837. [Res. Assoc. Brit. Flour Millers, Cereals Res. Stat., St. Albans, Herts.]

In estimating vitamin B_1 in mixtures containing *creta praeparata*, iron and nicotinic acid, made up with dry flour as a concentrate for enriching flour, it was found essential to use concentrated HCl for making the extracts. The best results were obtained when the vitamin concentrate was added slowly to the acid and the mixture was shaken vigorously during extraction and before samples were taken from subsequent dilutions for fluorimetric measurement. With tubes washed in acid, and other precautions, it was possible to obtain

very small blanks which could be ignored in calculating the results.—A. M. Copping.

1702

HOLT, C. V., BLUM, K. U. and HENRICH, W. D. Beitrag sur Frage der biologischen Activität des Cocarboxylase-disulfides. [**The biological activity of cocarboxylase disulphide.**] *Hoppe-Seyler's Ztschr.*, 1955, **302,** 68–72. [Physiol. Chem. Inst., Univ. Hamburg.]

Daily administration of 1 mg. neopyrithiamine hydrobromide per 100 g. bodyweight induced severe vitamin B_1 deficiency within from 7 to 12 days in rats of from 150 to 250 g. weight. Liver homogenates from the animals showed great reduction of pyruvate oxidation in comparison with normal livers. Addition of cocarboxylase or of cocarboxylase disulphide to the homogenate raised pyruvate oxidation to normal. It was calculated that from 5 to 7 times as much cocarboxylase disulphide was required to give the same effect as an optimum addition of cocarboxylase.

A. M. Copping.

1703

D'AGOSTINO BARBARO, A. Effetti della somministrazione di cocarbossilasi nel beri-beri sperimentale del colombo. [**Effects of giving cocarboxylase in experimental beriberi in the pigeon.**] *Arch. Sci. biol., Bologna,* 1955, **39,** 487–497. [Ist. Chim. Biol., Univ. Messina.]

Six pigeons were fed on a diet of polished rice, and blood sugar in the fasting birds was estimated every 4 or 5 days. When signs of deficiency appeared, an intramuscular injection of 1 mg. cocarboxylase was given immediately after a blood sample had been taken. An hour later blood was taken again and 0·5 mg. cocarboxylase was injected. After half an hour a third blood sample was taken. The bird then fasted for 24 hr. after which it continued to receive the polished rice diet with 0·5 mg. cocarboxylase daily, and further estimations of blood sugar were made. One pigeon died early. Full protocols are given for each bird. After the first treatment with cocarboxylase the signs of polyneuritis disappeared, and the raised blood sugar value fell sharply but then rose again, sometimes sharply, sometimes gradually. Suspension of treatment with cocarboxylase caused it to rise steeply. There was loss of weight with diarrhoea, and the pigeons died after 28, 52, 56, 80 and 88 days from the start of the experiment, but without reappearance of the signs of polyneuritis (see Title 369, Vol. 26).—E. M. Hume.

1704

DI STEFANO, E. and PREVITERA, L. Effetti della cistina e della cisteina sull'iperglicemia beriberica del colombo. [**Effect of cystine and of cysteine on the hyperglycaemia of beriberi in the pigeon.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 197–198. [Ist. Fisiol., Univ. Messina.]

Groups of 3 or 4 pigeons maintained on a diet of polished rice were given daily 130 or 350 mg. cysteine, or 130 mg. cystine, or no addition. Blood sugar was estimated at frequent intervals. Signs of polyneuritis appeared in the birds given no addition, and the blood sugar value rose; polyneuritis yielded to treatment with vitamin B_1 but the blood sugar, though reduced, did not fall to normal. The smaller dose of cysteine hindered the rise of blood sugar but had no other effect. The larger dose produced a toxic effect with nerve signs of cerebellar and labyrynthine involvement and high blood sugar; the birds died in spite of the administration of vitamin B_1. Cystine had no effect except a toxic one, and the pigeons died in spite of being given vitamin B_1.—E. M. Hume.

1705

BARBIERI, E. Sui rapporti tra acido ascorbico e cocarbossilasi. [**Relations between ascorbic acid and cocarboxylase.**] *Arch. Sci. biol., Bologna,* 1955, **39,** 443–449. [Ist. Chim. Biol., Univ. Padua.]

Groups of 5 or 6 female guineapigs weighing about 350 g. were maintained on a scorbutogenic diet with or without 15 mg. ascorbic acid every 3 days, or on a stock diet. Some were killed after 12 and some after 25 days, with or without an intraperitoneal injection 30 min. previously of 20 mg. vitamin B_1 per kg. bodyweight. Cocarboxylase was estimated in the liver, heart, striped muscle, brain and uterus, and in the liver only of those given vitamin B_1. In all organs of the guineapigs not given vitamin B_1, the amount of cocarboxylase declined with the progress of scurvy, the relative loss being greatest in the liver and least in the brain. After injection of vitamin B_1 the concentration of cocarboxylase was doubled in the liver of non-deprived guineapigs; the percentage increase after 12 days' deprivation was 75·4 and after 25 days' 54·2. The results with animals given stock diet were the same as with animals given the scorbutogenic diet and ascorbic acid.—E. M. Hume.

1706

ANDERSON, B. M. and PARKER, H. E. **The effects of dietary manganese and thiamine levels on growth rate and manganese concentration in tissues of rats.** *J. Nutrition,* 1955, **57,** 55–59. [Dept. Biochem., Purdue Univ. Agric. Exp. Stat., West Lafayette, Ind.]

Weanling rats were given purified diets lacking vitamin B_1 and containing 0·8, 5·0 or 50·0 mg. manganese per kg. Vitamin B_1 was depleted in 16 days in all groups irrespective of Mn supplement. Doses of 2·5, 16, or 100 μg. vitamin B_1

were then given daily for 4 weeks. In this period the amount of Mn given as well as of vitamin B_1 affected the rate of weight increase, but there was no evidence of antagonism between them. The Mn content of the liver and heart was estimated and found to depend on the Mn content of the diet and to be unaffected by the amount of vitamin B_1 given.
A. M. Copping.

1707

KOIKE, M. **Competitive inhibition of thiaminetriphosphate action by oxythiaminetriphosphate in the carboxylase system.** *J. Vitaminol., Japan*, 1955, **1**, 254–259. [Dept. Biochem., Med. Sch., Kumamoto Univ., Ninomaru.]

Oxythiamine triphosphate was synthesised by treating oxythiamine with orthophosphoric acid and purified by precipitation with cold acetone and alcohol. The pure triphosphate was tested with yeast carboxylase in presence of thiamine triphosphate. When oxythiamine triphosphate was added to the reaction mixture before thiamine triphosphate, it had an inhibitory effect, but oxythiamine did not inhibit cocarboxylase.—A. M. Copping.

1708

MATSUKAWA, T. and YURUGI, S. **On thiamine-destructive factor. 2.** *J. Vitaminol., Japan*, 1955, **1**, 173–179. [Res. Lab., Takeda Pharmaceutical Industries, Ltd., Osaka.]

In continuation of the experiments on chemical degradation of vitamin B_1 by sulphurous acid (Abst. 4873, Vol. 25) its effect on analogues of vitamin B_1 and on vitamin B_1 in presence of certain analogues was studied. Synthesis is described of analogues with nitrobenzyl, aminobenzyl and aminopyrimidyl groups and with ethyl and methyl groups in different positions. The destruction of vitamin B_1 was affected by amine substitution; the effect appeared to be related to that which occurs in the presence of aniline (Abst. 4873, Vol. 25). The similarity in effect of these chemical reactions to those of the enzyme thiaminase are discussed with reference to the observations of Sealock and Livermore (Abst. 403, Vol. 19).—A. M. Copping.

1709

RIGDON, R. H. and DRAGER, G. A. **Thiamine deficiency in sea lions (*Otaria californiana*) fed only frozen fish.** *J. Amer. Vet. Med. Assoc.*, 1955, **127**, 453–455. [Lab. Exp. Pathol., Univ. Texas Med. Branch, Galveston.]

One female and 2 male sea lions which had been fed on an exclusive diet of frozen fish died suddenly. The males were about 3 and 2 years old and the female about 7 years. Post-mortem examination showed myelin degeneration and heart changes, which were attributed to deficiency of vitamin B_1. The result is in harmony with other observations showing the presence in fresh fish of a substance which destroys vitamin B_1.—T. D. Bell.

RIBOFLAVIN

1710

CERLETTI, P. and SILIPRANDI, N. Separazione della riboflavina e dei suoi esteri fosforici mediante cromatografia su colonna di cellulosa. [**Separation of riboflavin and its phosphoric esters by chromatography on a cellulose column.**] *Acta vitaminol.*, 1955, **9**, 145–148. [Ist. Chim. Biol., Univ. Rome.] French, English, German and Spanish summaries.

The method of separation was studied on pure specimens of riboflavin, riboflavin phosphate and riboflavin pyrophosphate. An absorption column was prepared of Whatman Cellulose Powder B. Mixtures containing not more than 1 mg. of each substance in 4 ml. water were poured on the column and eluted with buffer solution of Na acetate at *p*H 5·1 or of trimethyl ammonium formate at *p*H 4·8. The yellow band quickly separated into 3 parts moving successively down the column, the pyrophosphate moving first, followed by the phosphate and then by riboflavin. The process took place as far as possible in absence of light.
E. M. Hume.

1711

CERLETTI, P. and SILIPRANDI, N. **Electrophoretic separation and determination of flavins.** *Biochem. J.*, 1955, **61**, 324–328. [Inst. Biol. Chem., Univ. Rome.]

A method of paper electrophoresis was applied to separate riboflavin, flavin mononucleotide, flavin adenine dinucleotide, lumichrome and lumiflavin. The fractions could be identified by their fluorescence in ultraviolet light. Recovery as measured by the fluorescence of the eluted spots tended to be incomplete but total recovery was obtained by measuring the extinction coefficients by spectrophotometer. Quantitative elution of the fractions could be obtained after electrophoresis of mixtures on a cellulose column. (See also preceding Abst.)—A. M. Copping.

1712

SULMAN, F. G. **A note on the resorption and excretion of riboflavine from aluminium monostearate suspensions in the rat.** *J. Pharm.*, 1955, **7**, 473–476. [Dept. Appl. Pharmacol.,

Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

Depots of riboflavin for slow absorption were made by injecting rats subcutaneously with a riboflavin suspension in 2 per cent. aluminium monostearate. Such a depot of 50 mg. took up to 105 days to be absorbed and smaller quantities took shorter periods, 20 mg. being absorbed in 52 days.

MIANI, N. and MUNARI, P. F. Sulla localizzazione della riboflavina e dei suoi derivati nella fibra gigante di *Sepia officinalis*. Ricerche con la tecnica cromatografica. [**Location of riboflavin and its derivatives in the giant nerve fibre of *Sepia officinalis*. Chromatographic investigation.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 265–267. [Ist. Anat., Univ. Padua.]

The axoplasm was separated from the myelin sheath in the giant fibres of several specimens of squid, and riboflavin, riboflavin phosphate and flavin adenine dinucleotide were estimated in extracts by paper chromatography. The greatest concentration in both parts of the nerve was of flavin adenine dinucleotide; riboflavin was less and riboflavin phosphate still less. Riboflavin phosphate was slightly more concentrated in the axoplasm, but the other two substances were more concentrated in the myelin sheath.

GUGGENHEIM, K. and DIAMANT, E. J. **Effect of riboflavin and choline deficiencies on water metabolism in rats.** *J. Nutrition*, 1955, **57**, 249–260. [Lab. Nutrit., Dept. Biochem., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

Young male rats were given a complete purified diet with or without riboflavin, and for testing the effect of deprivation of choline a high-fat and a low-fat diet were used. Rats deprived of riboflavin or choline showed delayed diuretic response to a water load. Injection of cortisone or adrenocorticotropic hormone increased excretion of urine by rats deprived of riboflavin, but had no effect on normal rats. Tests *in vitro* showed that the ability of the liver to inactivate pitressin was unchanged in riboflavin deficiency and decreased when choline was lacking. The effect of choline deficiency was apparent with diets containing 5 or 20 per cent. fat and was not related to the protein content of the diet. Administration of vitamin B_{12} or aureomycin to rats deprived of choline improved the capacity of the liver to inactivate pitressin. The different mechanisms affecting water metabolism in deficiency of riboflavin or choline are discussed with reference to previous observations in relation to deficiency of other members of the vitamin B complex (*cf.* Absts. 3019, Vol. 24; 460, Vol. 25).—A. M. Copping.

PURPURA, R. and LA GRUTTA, A. Lesioni epatiche nella aribоflavinosi sperimentale dei ratti e loro modificazioni dopo trattamento aureomicinico. Prime osservazioni. [**Lesions of the liver in experimental riboflavin deficiency of rats and their modification by treatment with aureomycin. Preliminary observations.**] *Sperimentale*, 1954, **104**, 106–121. [Ist. Clin. Pediat., Univ. Palermo.]

Three groups of from 3 to 6 rats weighing from 41 to 64 g. were given a diet of, per cent., casein 18, starch 68, butter 8, salts 4 and cod liver oil 2, with all B vitamins except riboflavin. One group received no addition, one after 52 days had 100 mmg. aureomycin per kg. bodyweight daily, and one had 0·5 mmg. riboflavin per kg. bodyweight daily [units are given as quoted but may be mg.]. A fourth group of 3 rats had a stock diet. The rats given riboflavin grew normally. Those deprived of riboflavin soon ceased to grow and showed signs of riboflavin deficiency; 2 died of pneumonia within 28 days. The rest of the group died in from 54 to 74 days. In 3 of the latter the liver at autopsy showed fatty degeneration. Those given aureomycin after 52 days resumed growth and signs of deficiency disappeared; 2 of them killed 13 days after aureomycin treatment began showed only residual signs of change in the liver.

KOTAKE, Y. and SHIBATA, Y. **On anthranilic acid excreted as a result of tryptophan administration to albino rats afflicted with V.B_2 deficiency and its inter-relations with 5-hydroxyanthranilic acid.** *Wakayama Med. Rep.*, 1955, **2**, 125–132. [Nutrit. Lab., Wakayama Med. Coll.]

Albino rats fed for about 4 weeks on a diet deficient in riboflavin excreted more anthranilic acid and xanthurenic acid and less creatinine in the urine in response to a dose of tryptophan than normal rats. The excretion of anthranilic acid was greatly reduced and the excretion of the others returned to normal when 5-hydroxyanthranilic acid was given simultaneously with the tryptophan; at the same time bodyweight tended to increase and the signs of deficiency to disappear.

MORRIS, H. P., WAGNER, B. P. and VELAT, C. A. **Tumors induced by 2-acetylaminofluorene in Buffalo-strain rats ingesting different levels of riboflavine.** *J. Nat. Cancer Inst.*, 1955, **16,** 489–493. [Lab. Biochem. Nat. Cancer Inst., Bethesda, Md.]

A constant amount of 6 mg. 2-acetylaminofluorene per 100 g. bodyweight was given weekly to rats of the Buffalo strain receiving diets containing 1, 2 or 10 μg. riboflavin per g. The amount of riboflavin in the diet did not appear to affect the incidence of tumours in the liver, but, with the highest dose of riboflavin, there seemed to be increased numbers of mammary tumours, squamous cell carcinomata in the ear duct, and tumours in sites other than the liver. With the lowest dose of riboflavin the carcinogen proved highly toxic, so that only about 40 per cent. of the animals survived long enough for tumours to develop.

COLES, R. and CUMBER, F. **Observations on the relationship between riboflavin, hatchability and clubbed down.** *J. Agric. Sci.*, 1955, **46,** 191–198. [Minist. Agric., London.]

A flock of White Leghorns was inbred for 6 years in an attempt to improve hatchability, but after rapid initial progress the hatchability of fertile eggs became stable at about 80 per cent. The standard diet provided about 3·6 μg. riboflavin per g., and clubbed down was sometimes found on chicks dead in shell.

In 1954, 7 pens were made up, each containing on the average 12 pullets and a cockerel; the pullets were of full sister families divided at random between the pens, which were on grass. Three rations were used, containing from 1·60 to 1·72, from 3·31 to 3·66 and from 13·72 to 14·20 μg. riboflavin per g. and called rations L, N and H. They were given to 2, 3 and 2 pens of birds from 14 January, egg collection began on 19 February, settings were made from 28 February to 21 March and then the groups on rations L and H exchanged diets and those on N went on as before. Settings continued until 22 April.

Total egg production for 63 days was almost 39 eggs per bird, from 35 to 36 of them fertile; there was no significant difference between pens. Pullets which started on ration L produced a larger number of fertile eggs after the change to ration H, about an equal proportion of chicks dead in shell, but fewer with clubbed down. Pullets started on ration H, after the change to ration L, produced a larger number of eggs, a larger percentage of chicks dead in shell and slightly more with clubbed down.

It is concluded that there was no significant effect of riboflavin on hatchability and that the presence of clubbed down, although readily influenced by riboflavin intake, was no indication that a higher riboflavin intake would improve hatchability. In a long discussion it is suggested that hatchability depends more on the supply of vitamin B_{12}, or more probably of an unidentified animal-protein factor, than on the supply of riboflavin.

HOFFER, A., LEVINE, M. N. and GEDDES, W. F. **Effect of leaf and stem rust on the content and distribution of riboflavin in hard red spring wheats at successive stages of kernel development.** *Cereal Chem.*, 1955, **32,** 347–355. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

The paper forms part of a thesis (Hoffer, Univ. Minnesota, 1944) and reports part of an extensive study made during the war under the Work Projects Administration on the effects of leaf and stem rust on wheat, hitherto mostly unpublished.

Riboflavin was estimated by the method previously described (Abst. 308, Vol. 15) in grain, chaff and straw from samples taken twice weekly (for method, see Abst. 3228, Vol. 12) from plants of Thatcher and Marquis wheat subjected to 3 degrees of controlled inoculation with leaf and stem rust, respectively. Kernel weight and moisture content of tiller were determined also. The results are presented in tables.

Ripe kernel weight and moisture content of tiller were reduced by the rusts. The total riboflavin content of the entire tiller decreased greatly during maturation of the grain; it was reduced by the rusts, especially the leaf rust. The total riboflavin content of the kernel increased to about the medium-dough stage (21 days after flowering) in Thatcher and then declined; in Marquis the decline was earlier. The rusts seemed to interfere with translocation of riboflavin into the kernel. The riboflavin concentration of the dry matter in all parts declined with maturity and was not much affected by the rusts.—W. M. Deans.

NICOTINIC ACID (NIACIN)

1721

HEMSLEY, L. A. **Suspected "blacktongue," nicotinic acid deficiency in a dog.** *Vet. Rec.*, 1955, **67**, 790. [Croydon.]

Blacktongue in a 3-year-old sheepdog is reported. The clinical signs and progress are described. The diet was of porridge and table scraps, but 2 other dogs on the same diet were healthy. There was no response to treatment with compound vitamin tablets, but 50 mg. nicotinic acid daily gave a good response within a few days. The diet was changed to contain a high proportion of animal protein.

1722

FRANCE, W. H. **Bracken poisoning in cattle.** *Vet. Rec.*, 1955, **67**, 802–803. [Kirkby Lonsdale.]

When signs of bracken poisoning have become obvious it is usually too late to save the affected animals. In an investigation of 3 herds with 52 animals in all, where bracken poisoning was suspected, blood samples were examined. Thrombocytes usually were few or absent. Prophylactic treatment with nicotinamide was tried and was successful if the thrombocyte count was not too low. It is suggested that where bracken poisoning is suspected frequent blood tests should be made, and nicotinamide given if the thrombocytes are low. In advanced cases blood transfusion and penicillin should be given, and the animals should be removed from the offending pasture.

VAN EYS, J., TOUSTER, O. and DARBY, W. J. **The purification of a glucuronide of nicotinic acid from rat urine.** *J. Biol. Chem.*, 1955, **217**, 287–292. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Nicotinoyl glucuronide was isolated from rat urine by precipitation with lead acetate, decomposition of the lead salt and adsorption on Dowex 50. Subsequent paper chromatography and chemical and microbiological studies established the identity of the glucuronide as β-nicotinoyl-D-glucuronide. It appeared to be a normal constituent of rat urine, since 70 μg. were isolated from 10 ml. urine without previous administration of nicotinic acid.—A. M. Copping.

1725

HAYMAN, S., SHAHINIAN, S. S., WILLIAMS, J. N. (Jr.) and ELVEHJEM, C. A. **Effect of 3-acetylpyridine on pyridine nucleotide formation from tryptophan and niacin.** *J. Biol. Chem.*, 1955, **217**, 225–228. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Weanling male rats were depleted of liver pyridine nucleotide by a diet free from protein and nicotinic acid. After a depletion period of from 2 to 3 weeks a single dose of 2·5 mg. nicotinic acid or 4·15 mg. tryptophan with or without 2·61 mg. acetylpyridine was given and rats were killed at intervals up to 18 hr. afterwards. Acetylpyridine alone proved highly toxic to depleted rats, but apparent pyridine nucleotide increased in the liver. When acetylpyridine was given with tryptophan or nicotinic acid there was increased formation of pyridine nucleotide in the liver, as estimated by the spectrophotometric method of Feigelson *et al.* (Title 3126, Vol. 20). The high mortality which occurred from 4 to 5 hr. after administration of acetylpyridine alone was prevented when tryptophan or nicotinic acid was given at the same time or shortly afterwards.—A. M. Copping.

PORCELLATI, G. Attività nicotinamidasica: determinazione spettrofotometrica. [**Spectrophotometric estimation of nicotinamidase activity.**] Disintegrazione cellulare ed idrolisi enzimatica della nicotinamide. [**Cellular disintegration and enzymic hydrolysis of nicotinamide.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 141–144; 145–146. [Centro Enzimol., presso Ist. Chim. Biol., Univ. Naples.]

A spectrophotometric method was used to estimate the nicotinic acid derived from nicotinamide by enzymic hydrolysis in homogenates of rat's and rabbit's brain, liver and kidney. Some nicotinic acid was formed by all 3 organs of both species, the percentage of the substrate transformed being in the rat 10·2 for liver, 12·5 for brain and 14·8 for kidney; the corresponding values for the rabbit were 4·5 for liver, 6·5 for kidney and 8·2 for brain. When the amount of nicotinamide in the substrate was increased with rat homogenates, the amount hydrolysed increased, but the percentage did not change greatly.

In the same way the production of nicotinic acid by homogenates and slices of rat liver and kidney was compared. The amount formed by slices was always somewhat less. Suggestions are made to account for the difference.—E. M. Hume.

1728

BORIANI, A. Azione della'acido nicotinico e di alcuni suoi derivati sull'attività della colinesterasi serica. [**Action of nicotinic acid and some of its derivatives on the activity of serum cholinesterase.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 135–136. [Ist. Farmacol., Univ. Modena.]

Percentage inhibition of cholinesterase in horse serum *in vitro* by nicotinic acid and certain of its derivatives was for nicotinic acid 48·4, nicotinamide 56·6, trigonellin 100·0, N^1-methyl-6-hydroxynicotinic acid 33·7, N^1-methyl-2-hydroxynicotinic acid 81·4, 2-hydroxytrigonellinamide 37·3 and 6-hydroxytrigonellinamide 37·3.—E. M. Hume.

FISHER, H., SCOTT, H. M. and JOHNSON, B. C. **Quantitative aspects of the nicotinic acid-tryptophan interrelationship in the chick.** *Brit. J. Nutrition*, 1955, **9**, 340–349. [Div. Animal Nutrit. and Dept. Animal Sci., Univ. Illinois, Urbana.]

Day-old male chicks were fed on a basal diet containing, per cent., hydrolysed casein 22, salts 5·3, maize oil 3, cellulose 3, glucose 64, choline chloride 0·2, DL-methionine 0·3, L-arginine hydrochloride 1·0 and glycine 1·0, with adequate amounts of vitamins A, D, E and all B vitamins. Growth tests began after 3 days, with 4 chicks in each group, receiving the diet supplemented with from 0·1 to 0·4 per cent. L-tryptophan without nicotinic acid, and with from 2·5 to 20 mg. nicotinic acid per cent. In absence of nicotinic acid an average bodyweight of 138 g. was attained after 3 weeks with 0·2 per cent. tryptophan, or with 0·15 per cent. when 2·5 mg. nicotinic acid per cent. was given as well. With the marginal amount of 0·10 per cent. tryptophan no benefit was obtained from larger amounts of nicotinic acid up to 20 mg. per cent. There were some scattered cases of perosis.

When the basal diet was further supplemented with, per cent., L-histidine 0·3, DL-threonine 0·8 and L-leucine 0·65 at the expense of glucose, perosis was frequent and more tryptophan and nicotinic acid were needed for protection.

When maize replaced glucose in the basal diet, 0·15 per cent. tryptophan with 1·25 mg. nicotinic acid per cent. was adequate for growth, but perosis was frequent. Reduction of the casein from 22 to 16 per cent. improved growth and there was less perosis. It is suggested that, by reduction in quantity and quality of the protein in the diet, the tryptophan that could be used for protein synthesis may have been reduced, so that more may have been available for synthesis of nicotinic acid. On the maize diets the amount of nicotinic acid needed for optimum growth and prevention of perosis was about 10 mg. per cent.; the increased need is attributed to a stress condition imposed by the amino-acid composition and balance of maize. No support is given for the presence of a toxic principle in maize responsible for perosis.

Practical starting rations containing, per cent., soya bean 30 or fishmeal 23 with maizemeal 54 or 65, and tryptophan 0·31 or 0·26 were adequate for growth to weights between 275 and 297 g. at 3 weeks of age, and were not improved by addition of up to 5·6 mg. nicotinic acid per cent. (See also Absts. 1949, 1950, Vol. 22.)—H. Chick.

1730

ADAMO, G. Il contenuto in acido nicotinico nel caffè. [**Nicotinic acid content of coffee.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 79–82. [Ist. Merceol., Univ. Bari.]

Trigonellin and nicotinic acid were estimated chemically in alcoholic extracts of green coffee and in roasted coffee, which in the process of roasting is brought to a temperature up to 220° C. In 3 kinds of coffee the percentage of trigonellin before roasting ranged from 1·15 to 1·28, and after roasting from 0·24 to 0·35. The percentage of nicotinic acid before roasting was less than 0·001, and after roasting ranged from 0·47 to 0·51. It is pointed out that in coffee less strongly roasted than is customary in Italy, less nicotinic acid is likely to be produced from trigonellin.—E. M. Hume.

VITAMIN B_6 (PYRIDOXINE, ADERMIN)

1731

FUJITA, A., MATSUURA, K. and FUJINO, K. **Fluorometric determination of vitamin B_6. 1. Determination of pyridoxine.**

FUJITA, A., FUJITA, D. and FUJINO, K. **2. Determination of pyridoxamine. 3. Fractional determination of pyridoxal and 4-pyridoxic acid.**

FUJITA, A. and FUJINO, K. **4. Fractional determination of vitamin B_6 components and 4-pyridoxic acid in the urine.** *J. Vitaminol., Japan*, 1955, **1**, 267–274 ; 275–278 ; 279–289 ; 290–296. [Biochem. Lab., Kitasato Inst., Minato-ku, Tokyo.]

1. A method was devised for estimating pyridoxine by converting it into the fluorescent lactone derivative of 4-pyridoxic acid (*cf.* Huff and Perlzweig, Abst. 3199, Vol. 14). Pyridoxine was extracted from tissues with dilute H_2SO_4, the acid was neutralised by barium hydroxide, and interfering substances were removed by adsorption on Permutit. Pyridoxine was converted to 4-pyridoxic acid by oxidation with permanganate and thence to the lactone by heating with 6*N* HCl. Fluorescence of the product was measured in alkaline solution at *p*H 10. Other analogues of vitamin B_6 did not interfere with the estimation of pyridoxine by this procedure.

2. Pyridoxamine was estimated by the method just described after preliminary treatment of extracts with sodium nitrite to deaminate pyridoxamine and convert it to pyridoxine. The nitrite treatment did not affect pyridoxine and pyridoxal in the extracts and their presence did not interfere with estimation of pyridoxamine.

3. Pyridoxal was oxidised to 4-pyridoxic acid by heating with ammoniacal silver nitrate. Both pyridoxal and 4-pyridoxic acid were extracted from tissues by the acid and alkaline treatments required to obtain free pyridoxal. The 4-pyridoxic acid was removed by adsorption on an ion-exchange substance and pyridoxal was then converted to pyridoxic acid lactone for measurement of fluorescence. By this method it was possible to measure all components of vitamin B_6, and a table is given showing values for tissues and foods, with comparative figures reported by investigators using other methods. From the results the fluorimetric method seemed to be satisfactory.

4. In order to apply the fluorimetric method of estimating vitamin B_6 components to urine it was essential first to remove 4-pyridoxic acid with ion-exchange resin. Pyridoxal could be selectively adsorbed on another suitable resin and pyridoxine on Permutit. Details of the fractional separation of the components are given, with results from studies of normal urine and blood.

BIANCHI DONNASIBILLA, L. and MAGGIORA, L. Carenza piridossinica da desossipiridossina nel ratto. Studio del sangue periferico e del midollo osseo. [**Pyridoxine deficiency produced by deoxypyridoxine in the rat : the peripheral blood and bone marrow.**] *Acta vitaminol.*, 1955, **9**, 211–217. [Ist. Clin. Pediat., Univ. Pavia.] French, English, German and Spanish summaries.

Of 30 rats weighing from 150 to 200 g., fed on a stock diet, 20 were given daily by intramuscular injection 400 μg. deoxypyridoxine. Blood from the tail was examined after 20, 30, 40 and 50 days and, at the same intervals, rats were killed for comparison of the bone marrow with that of the 10 normal rats. In the peripheral blood there was no change in red cells, lipids or polysaccharides. Of the white cells, the lymphocytes diminished progressively and severely. The granulocytes diminished slightly at first, then increased up to the 40th day, and again fell, the number being less than the initial one by the 50th day. In the bone marrow there was no change affecting the red cells, but there was an increase of immature eosinophils, a slight progressive increase in the number of haemocytoblasts, and a decrease in the number of neutrophil myelocytes and metamyelocytes.—E. M. Hume.

1733

BIANCHI DONNASIBILLA, L. and CORTESI, M. Ulteriori indagini sui poteri immunitari nella carenza piridossinica sperimentale da desossipiridossina. [**Further studies of immunising power in experimental pyridoxine deficiency produced by deoxypyridoxine.**] *Acta vitaminol.*, 1955, **9**, 219–222. [Ist. Clin. Pediat., Univ. Pavia.] French, English, German and Spanish summaries.

Of 18 normally fed rabbits weighing from 900 to 1200 g., 10 were injected with 3 mg. deoxypyridoxine daily. On the 5th and 8th day 2 in each group were injected with 500 mg. DL-tryptophan. Those given deoxypyridoxine responded with an excretion of xanthurenic acid which proved them to be in a state of deficiency of vitamin B_6. On the first and 10th day of the experiment all the rabbits were injected with a typhoid vaccine, and on the first and 5th day with a diphtheria toxoid. On the 10th, 20th and 30th day, the degree of immunity induced was measured by

estimating in the serum the amount of H and O agglutinins and the degree of haemagglutination, respectively. Both groups showed an immune reaction which was not diminished by deficiency of vitamin B_6 induced with deoxypyridoxine.

WERTMAN, K., O'LEARY, W. M. and SMITH, L. W. **The effects of pyridoxine deficiency on some physiological factors of importance in resistance to infection.** *J. Nutrition*, 1955, **57**, 203–214. [Div. Bacteriol., Dept. Biol. Sci., Univ. Pittsburgh, Pa.]

Rats weighing about 45 g. were given a purified diet with or without vitamin B_6. Some of those receiving the vitamin had their food intake restricted to that of the deprived rats. After 8 weeks samples of blood were taken from the tail and an intraperitoneal injection of Locke's solution and nutrient broth was given to cause inflammation. Twelve hr. later the rats were anaesthetised and bled by heart puncture. Cell counts were made on the peripheral blood samples, the bone marrow and the inflammatory exudates. No difference was found in total erythrocyte count between the groups. Microcytosis and leucopenia occurred in blood of rats deprived of vitamin B_6 and not of those with restricted food intake. The deprived rats showed an increase of polymorphonuclear leucocytes and a decrease of lymphocytes. Cellular migration to the inflamed area was less in deficient rats. Granulocytosis and lymphopenia were greater in inflammatory exudates and bone marrow of deprived rats than of those given the vitamin, whether the food was restricted or not. There was no change of capillary permeability in any group.—A. M. Copping.

1735

BOONE, I. U., TURNEY, D. F. and LANGHAM, W. H. **Isoniazid in vitamin B_6-deficient rats.** *J. Lab. Clin. Med.*, 1955, **46**, 549–559. [Los Alamos Sci. Lab., Univ. California, N. Mex.]

Four groups of 20 rats received from 6 weeks of age a basal diet deficient in vitamin B_6 with daily supplements of 50 μg. pyridoxine, or 100 μg. deoxypyridoxine, or 50 mg. isoniazid per kg. bodyweight, or 120 mg. isoniazid per kg. bodyweight and 50 μg. pyridoxine. Some animals in the groups given pyridoxine had the food intake restricted. Weight loss was most severe in rats given isoniazid alone, and this group and those given isoniazid and pyridoxine had convulsions but no acrodynia. Severe acrodynia occurred in rats given deoxypyridoxine but they did not have convulsions. Excretion of xanthurenic acid in response to a dose of tryptophan was raised in rats given isoniazid but not as much as in those given deoxypyridoxine. Atrophy of the thymus gland occurred in rats given deoxypyridoxine or isoniazid. All signs of metabolic disturbance due to isoniazid, including convulsions, disappeared rapidly when large doses of pyridoxine were given. Toxic effects of isoniazid were more severe in animals deprived of vitamin B_6 than in normal animals. The results are discussed with reference to the possible occurrence of vitamin B_6 deficiency in patients treated with isoniazid.—A. M. Copping.

1736

CHARCONNET-HARDING, F. and ABRAHAM, J. Influence comparée de la carence B_6 et de l'isonicotinylhydrazide (INH) sur le métabolisme du L-tryptophane et du D-tryptophane chez le rat blanc. [**Comparative effect of vitamin B_6 and *iso*nicotinylhydrazide on the metabolism of L- and D-tryptophan in the white rat.**] *C.R. Acad. Sci.*, 1955, **241**, 993–995.

In rats receiving *iso*nicotinylhydrazide the excretion of indole derivatives in response to a dose of D- or DL-tryptophan closely resembled that found in rats deprived of vitamin B_6, but a dose of L-tryptophan produced no increase of indole excretion, an effect different from that reported in man (Biehl and Vilter, Abst. 4442, Vol. 24).

1737

SANDMAN, R. and SNELL, E. E. **Some effects of ω-methyl analogues of vitamin B_6 in rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 63–67. [Biochem. Inst., Univ. Texas, Austin.]

When large doses of ω-methylpyridoxal, ω-methylpyridoxamine or ω-methylpyridoxine were given with a diet lacking vitamin B_6, rats gained weight for about 4 weeks but weight gain then slackened and they died. Convulsive seizures occurred within the first 2 weeks of treatment with the ω-methyl compounds even when weight increase was still good. Convulsions and weight loss were prevented if pyridoxal was given in addition to the ω-methyl compounds. Enzyme studies showed that transaminase and thionase activities were low in rats given ω-methyl analogues. ω-Methylpyridoxal phosphate had only about 10 per cent. of the activity of pyridoxal phosphate as an activator of transaminase. The metabolic role of the ω-methyl analogues is discussed.

HURWITZ, J. **Enzymatic phosphorylation of vitamin B_6 analogues and their effect on tyrosine decarboxylase.** *J. Biol. Chem.*, 1955, **217**, 513–525. [Dept. Biochem., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

The possibility of enzymic phosphorylation by a kinase preparation in presence of adenosine triphosphate was studied with 11 analogues of

pyridoxine, pyridoxal and pyridoxal phosphate being used as standards for comparing the effects of analogues and phosphates on tyrosine decarboxylase. Analogues substituted in the 6 position of the ring could not be phosphorylated. All analogues which formed phosphates had the 6 position free and the 5 position occupied by a hydroxymethyl group to which the phosphate group could be attached. The structural requirements for union of pyridoxal phosphate and tyrosine decarboxylase could not be defined from the reactions obtained with the analogues.

BLAKLEY, R. L. **The interconversion of serine and glycine : participation of pyridoxal phosphate.** *Biochem. J.*, 1955, **61,** 315–323. [Dept. Biochem., John Curtin Sch. Med. Res., Australian Nat. Univ., Canberra.]

The activity of an enzyme, prepared from rabbit liver, which catalyses the synthesis of serine from glycine and formaldehyde, was studied manometrically. With successive purifications, increased requirement for pyridoxal phosphate was shown. The enzyme was almost completely inactivated by incubation at *p*H 9 and 37° C. for from 15 to 30 min. It could be re-activated by brief incubation in presence of pyridoxal phosphate at *p*H 7·2. Re-activation was inhibited by deoxypyridoxine phosphate and by pyridoxine phosphate. A number of metals were tested for participation in the enzymic synthesis of serine ; all exhibited inhibition and none activated the reaction. Ethylenediamine tetra-acetate did not inhibit synthesis. Direct evidence for formation of Schiff's bases between pyridoxal phosphate and amino-acids was obtained in spectrophotometric studies which gave further evidence about the mechanism of enzyme reactions employing pyridoxal phosphate.—A. M. Copping.

CHRISTENSEN, H. N. **Possible role of chelation between alkali metals and pyridoxal in biological transport.** *Science*, 1955, **122,** 1087–1088. [Dept. Biochem. Nutrit., Tufts Univ. Sch. Med., Boston, Mass.]

Spectrophotometric and titrimetric evidence was obtained that chelated compounds of pyridoxal and magnesium, calcium, lithium, sodium and potassium were formed when pyridoxal was added to a solution of a metal chloride containing small quantities also of a metal hydroxide. The strongest chelation occurred with Mg, Li and Na, which are the metals that cause the apotryptophanase and pyridoxal phosphate system to dissociate, whereas K tends to stabilise the enzyme system. A possible role of the metallic complexes in transfer of metals through cellular boundaries is suggested.—A. M. Copping.

GINOULHIAC, E., TENCONI, L. T. and VANDELLI, I. Influence des stéroïdes sexuels sur le métabolisme du tryptophane. [**Influence of sex steroids on metabolism of tryptophan.**] *Acta vitaminol.*, 1955, **9,** 193–198. [Lab. Direction Méd. Centrale, Lepetit S.p.A., Milan.] Italian, English, German and Spanish summaries.

The work continues that reported in Abst. 4279, Vol. 23.

In adult rats with ovaries removed, the amounts of kynurenine and diazo substances found in the urine after tryptophan had been given were much less than in normal rats ; the amount of xanthurenic acid was unchanged 42 days after operation but increased after 150 days.

Treatment with folliculin 500 days after operation reduced the output of xanthurenic acid to normal and, in the largest dose, caused a particularly high output of kynurenine and diazo substances. Cortisone and hydrocortisone had similar effects, but the increases in excretion of kynurenine and diazo substances were less. Progesterone and testosterone were without effect, and progesterone failed to modify the effect of folliculin. Hexoestrol behaved like folliculin. Folliculin reduced the high output of xanthurenic acid in intact rats deprived of pyridoxine, but not to the normal amount.

It is concluded that the effects of pyridoxine and folliculin on tryptophan metabolism are not identical.—D. Duncan.

1743

EDDY, A. A. and KIRSOP, B. **Accumulation of indole metabolites and of anthranilic acid in cultures of *Saccharomyces cerevisiae* deprived of pyridoxin.** *J. Inst. Brewing*, 1955, **61,** 382–385. [Brewing Indust. Res. Found., Nutfield, Surrey.]

In cultures of 10 out of 13 strains of *Saccharomyces cerevisiae* in a medium without pyridoxine, a positive indole reaction was detected with the Ehrlich reagent. The cultures containing indole

showed blue fluorescence in ultraviolet light. From a detailed investigation of one culture, indole, tryptophol and an unidentified indole derivative were isolated by ether extraction and paper chromatography. The blue fluorescence was found to be due to anthranilic acid. The role of these metabolites in the synthesis of tryptophan by micro-organisms is briefly discussed.

PANTOTHENIC ACID

1744

DUBOST, S., BRIGNON, J. and WOLFF, R. Sur la croissance de *Lactobacillus helveticus* en présence d'acide pantothénique et de pantéthéine et son application au dosage microbiologique du coenzyme A dans les tissus. [**Growth of *Lactobacillus helveticus* in the presence of pantothenic acid and pantotheine and its application to the microbiological estimation of coenzyme A in tissues.**] *C.R. Soc. Biol.*, 1955, **149,** 1008–1011. [Lab. Chim. Biol., Fac. Méd., Nancy.]

With turbidity as criterion it was shown that pantotheine was a growth factor for *Lactobacillus helveticus*. A characteristic alteration in shape of the curve of response was obtained when pantothenic acid and pantotheine were present. Pantotheine was formed when coenzyme A was treated with intestinal phosphatase, and the coenzyme A content of tissues could thus be estimated by the use of *L. helveticus*. Results obtained with the method and with the double enzyme technique of Lipmann (Abst. 466, Vol. 19) were in good agreement.

LEFEBVRES-BOISSELOT, J. Contribution à l'étude des besoins en acide pantothénique de l'embryon et du foetus. Résultats expérimentaux obtenus chez le rat. [**Pantothenic acid requirements of the embryo and foetus. Experimental results obtained with the rat.**] *Arch. Sci. physiol.*, 1955, **9,** 145–155. [Lab. Physiol., École Hautes-Études, Paris.]

The progress and results of gestation were recorded in rats receiving amounts of pantothenate ranging from 0 to 150 μg. daily. With up to 10 μg. pantothenate in a purified diet all the embryos were resorbed. With from 20 to 25 μg. about 60 per cent. of the embryos were resorbed and of the young born half showed abnormalities. With increasing amounts the number of resorbed embryos and deformed young decreased. The least amount permitting all young to be normal was 50 μg. daily. When the dose was from 40 to 45 μg. almost 10 per cent. of the young were deformed. The requirement of the foetus appeared to decrease with age according to a curve constructed from results obtained in the present study and reported by other observers.—A. M. Copping.

1746

STOTHERS, S. C., SCHMIDT, D. A., JOHNSTON, R. L., HOEFER, J. A. and LUECKE, R. W. **The pantothenic acid requirement of the baby pig.** *J. Nutrition*, 1955, **57,** 47–53. [Michigan State Coll., East Lansing.]

Baby pigs removed from the sow from 72 to 96 hr. after birth were given a basal synthetic milk without pantothenic acid or with 5·0, 7·5, 10·0, 12·5 or 15·0 mg. Ca pantothenate per kg. solids. Diarrhoea occurred in from 14 to 28 days in those deprived of pantothenate, and those which survived developed signs of inco-ordination from 7 to 10 days later. Injection of 100 mg. pantothenate daily cured the diarrhoea and weakness. Pigs in groups receiving less than 10·0 mg. pantothenate per kg. milk solids developed diarrhoea within 38 days, and there was some inco-ordination and weakness of the hind quarters. At least 12·5 mg. pantothenate per kg. solids was required for normal growth and efficiency of use of feed.

Histological examination of tissues from the deficient pigs showed lesions in the large intestine and nervous system like those described by Wintrobe (Abst. 3444, Vol. 10).

1747

SERONDE, J. (JR.), ZUCKER, L. M. and ZUCKER, T. F. **The influence of duration of pantothenate deprivation upon natural resistance of rats to a corynebacterium.** *J. Infect. Dis.*, 1955, **97,** 35–38. [Dept. Pathol., Coll. Phys. Surg., Columbia Univ., New York.]

In continuation of previous studies (Absts. 4450, 4451, Vol. 24) the resistance of 2 strains of rats to *Corynebacterium* 197 was examined when they were deprived of pantothenate for 10, 20, 30 or 40 days from weaning. One strain proved far more susceptible than the other, developing severe and fatal infections in 20 days, while the less susceptible did so only after 40 days' deprivation. With the highly susceptible strain and with another related strain the effect of varying the size of the inoculum was investigated for 30 days without pantothenate. There was little difference in response between undiluted broth and a broth diluted 1 in 5 with saline. With more dilute broth, lesions were less severe. Again there were differences in susceptibility between the strains of rats.—A. M. Copping.

1748

ASCHKENASY, A. (with NEVEU, C.) Études sur les changements pondéraux de divers organes et tissus provoqués par la surrénalectomie chez le rat. Rôle joué par le facteur temps, le sexe des animaux et la teneur du régime en protéines et en acide pantothénique. [**Study of weight changes in organs and tissues induced by adrenalectomy in the rat. Role of time, sex and the protein and pantothenic acid content of the diet.**] *Arch. Sci. physiol.*, 1955, **9**, 157–181. [Hôp. Pitié, Paris.]

The early and late results of adrenalectomy were studied in 142 rats of about 150 g. original weight. During the week after operation there was some loss of bodyweight, but during the next 5 weeks adrenalectomised male rats on a normal diet grew as well as intact males, and the weight increase of adrenalectomised females was slightly above that of intact females. If the diet was low in protein the adrenalectomised rats' appetite was poor and they lost weight. With only 2 per cent. protein in the diet weight loss was severe and the rats died. When extra pantothenic acid was added to a normal diet adrenalectomised male rats grew a little better than intact animals.

The weight of the muscles, liver, kidney, testes, seminal vesicles, preputial glands, spleen and thymus, thyroid and submaxillary glands was recorded for comparable adrenalectomised and intact rats. With a normal diet there was hypertrophy of the lymphoid organs and decrease in the weight of the liver after the operation. Hypertrophy of the spleen disappeared after 6 weeks but that of the muscle, thyroid gland and testes increased with time of survival. Female rats showed no change in the weight of the liver after adrenalectomy, but had greater hypertrophy of the thymus gland and spleen than males. With a limited protein intake, hypertrophy of the organs and tissues was almost completely abolished in both males and females, but liver atrophy was increased in males, an effect which could be prevented by large doses of pantothenic acid.

BONOMO, B. and MAINARDI, L. Studio radiologico degli effetti dell'acido pantotenico sulla funzione motoria dell'intestino nei ratti a midollo reciso. [**Radiographic study on the effects of pantothenic acid on the motor function of the intestine in rats with the spinal cord cut.**] *Acta vitaminol.*, 1955, **9**, 163–171. [Ist. Radiol., Univ. Pavia.] French, English, German and Spanish summaries.

Normally fed rats weighing from 200 to 300 g. were given a barium meal after a fast of 3 hr. In some the spinal cord was cut at the level of the fourth dorsal vertebra. At intervals for 24 hr. X-ray photographs were taken. There was marked retardation in the passage of the barium meal in the rats in which the cord had been cut. The experiment was repeated with 2 groups of 15 rats; the cord was cut in all. To one group an intramuscular injection of 5 mg. Ca pantothenate per kg. bodyweight was given 15 min. and 15 hr. after the barium meal. The X-ray photograph was taken after 24 hr., when it was apparent that the barium meal had passed out of the small intestine in 13 of the rats given Ca pantothenate and in only 4 of those not given it.—E. M. Hume.

1750

CHERNICK, S. S., MOE, J. G. and SCHWARZ, K. **Dietary necrotic liver degeneration and coenzyme A.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 520–523. [Lab. Biochem. Nutrit., Nat. Inst. Arthritis Metabol. Dis., Nat. Insts. Health, Bethesda, Md.]

Necrotic degeneration of the livers of rats caused by a diet containing 30 per cent. of torula yeast as sole source of protein, lacking vitamin E and low in cystine (Abst. 5235, Vol. 21; 1037, Vol. 22) was found to be preceded by a metabolic lesion characterised by reduced uptake of oxygen. Low values for coenzyme A were found in affected livers and addition of vitamin E to the diet did not raise the coenzyme A content of the liver, but almost normal values were obtained if cystine, methionine or cysteine was added. The effect of supplements on the content of coenzyme A was not related to their protective effect against necrotic degeneration.—A. M. Copping.

1751

TURCHETTO, E., INFANTE, R. and SECHI, A. M. Influenza della tiroxina sulla attività lipotropa dell'acido pantotenico. [**Effect of thyroxine on the lipotropic activity of pantothenic acid.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 233–234. [Ist. Chim. Biol., Univ. Bologna.]

Fifty rats weighing from 125 to 130 g. in 10 groups were maintained for 16 days on a diet high in fat, low in protein and containing 0·5 per cent. cholesterol. They received additions of pantothenic acid with or without thyroxine or neither. Total lipids were estimated in the liver. The mean values, per cent., were for no addition 16·2, for 10, 20 and 50 mg. pantothenic acid daily 8·0, 8·0 and 6·1, and for the same amounts of pantothenic acid with 100 or 200 μg. thyroxine daily from 2·0 to 3·5.—E. M. Hume.

1752

SWELL, L., BOITER, T. A., FIELD, H. (Jr.) and TREADWELL, C. R. **Pantothenate and dietary cholesterol in the maintenance of blood and tissue cholesterol esters.** *J. Nutrition*, 1955,

57, 121–132. [Gen. Med. Res., Veterans Admin. Centre, Martinsburg, W. Va.]

After a preliminary study of blood cholesterol values with a normal diet, rats weighing from 60 to 70 g. were given a purified diet with no fat or with 25 per cent. olive oil, and with or without 1 per cent. cholesterol and 0·5 per cent. sodium taurocholate. Some groups were deprived of pantothenate and others received it. Blood cholesterol was estimated after 10, 20 and 35 days of the diets; the rats were then killed and the liver and adrenal glands were analysed.

No change in blood cholesterol occurred when a fat-free diet without added cholesterol was given to rats with or without pantothenate. When cholesterol and bile salt were added to the fat-free diet, rats deprived of pantothenate showed very little rise in blood cholesterol, but rats not deprived of pantothenate showed a rise. Addition of fat to the diet increased blood cholesterol further in non-deprived animals and raised it in those deprived of pantothenate. The cholesterol content of the liver and adrenal glands was increased in all animals which had high values for blood cholesterol. In pantothenate-deficient rats most groups showed low values for adrenal cholesterol except where addition of fat, cholesterol and bile salts to the diet had raised blood cholesterol. The amount of cholesterol in the liver was less in rats deprived of pantothenate than in those having comparable diets containing pantothenate.

1753

BRÆKKAN, O. R. **Role of pantothenic acid in the reproductive cycle of ovaries in fish.** *Nature*, 1955, **176,** 598. [Govt. Vitamin Lab., Norwegian Fish. Res. Inst., Bergen.]

Pantothenic acid was estimated microbiologically in the ovaries of young and mature cod (*Gadus morrhua*) during the months from April to September. The content, up to 375 μg. per g. fresh weight, was highest in ovaries of young and mature fish in the early stages of regeneration after spawning. Later in the regeneration cycle and during maturation of the reproductive organs, the pantothenic acid content of the ovaries decreased to values of from 10 to 30 μg. per g. tissue shortly before spawning. The maximum values are the highest reported for pantothenic acid from natural sources.—A. M. Copping.

1754

PIERPOINT, W. S., HUGHES, D. E., BADDILEY, J. and MATHIAS, A. P. **The phosphorylation of pantothenic acid by *Lactobacillus arabinosus* 17-5.** *Biochem. J.*, 1955, **61,** 368–374. [Med. Res. Counc. Unit Res. Cell Metabol., Dept. Biochem., Univ. Oxford.]

When dried cells of *Lactobacillus arabinosus* were incubated with pantothenic acid in presence of adenosine triphosphate and phosphate buffer the pantothenic acid was converted into a phosphoric ester. Treatment with phosphatase gave complete recovery of pantothenic acid. The presence of fluoride increased the extent of phosphorylation. A study of the effect of intestinal phosphatase on known pantothenic phosphates showed that the phosphate formed by *L. arabinosus* was pantothenic-4′-phosphate. The result was confirmed by chromatography and by tests of stability to acid and alkali.—A. M. Copping.

1755

WIELAND, T., MAUL, W. and MÖLLER, E. F. Verfolgung des Schicksals radioaktiver Pantothensäure in Mikroorganismen mit Hilfe der Papierelektrophorese. [**Fate of radio-active pantothenic acid in micro-organisms followed by electrophoresis on paper.**] *Biochem. Ztschr.*, 1955, **327,** 85–92. [Inst. Org. Chem., Univ. Frankfurt a.M.]

The synthesis of pantothenic acid containing ^{14}C in the β-alanine group was achieved, starting from ^{14}C-cyanoacetic ethyl ester. The use of the marked pantothenic acid by *Streptobacterium plantarum* and by *Saccharomyces carlsbergensis* was studied with the aid of paper chromatography and electrophoresis. All radio-activity appeared to migrate to the anode, so that the pantothenic components intermediate in the synthesis of coenzyme A by the micro-organisms were acidic and not neutral or basic derivatives. The paper chromatograms from extracts of cultures of the organisms showed different distributions of the components, which were identified as dephosphocoenzyme A, 4-phosphopantothene, panthenylcysteine, coenzyme A and pantothenic acid for *Streptobacterium*, and as pantothenic acid, coenzyme A and 4-phosphopantothenic acid for *Saccharomyces*. The possible metabolic pathways suggested by the observations are discussed.—A. M. Copping.

BIOTIN

1756

KATSH, S., KOSARICK, E. and ALPERN, J. **Effect of biotin deficiency on body and organ growth and accessory reproductive structures in male rats.** *Growth*, 1955, **19,** 45–56. [Kerckhoff Labs. Biol., California Inst. Technol.]

Groups of young male albino rats were given normal or purified diets with and without

sulphaguanidine, or diets containing egg white and sulphaguanidine with or without added biotin. Other groups had normal diets in amounts restricted to those of rats given egg white and no biotin, or those given a purified diet.

The earliest signs of biotin deprivation appeared in rats given egg white and the lesions were prevented by inclusion of biotin in the diet. When severe biotin deficiency developed after 60 days all the rats in the group and in comparable groups were killed. Others were kept for 100 days on the experimental diets. Bodyweight, and weight of the pituitary, thyroid, adrenal, prostate and thymus glands and of the spleen and seminal vesicles were recorded. Testicular lesions were present in rats given egg white and no biotin. No other histological change was noted, and changes in organ weights appeared to be related to bodyweight as determined by limited or unlimited food intake.—A. M. Copping.

1757

DELOST, P. and TERROINE, T. Étude des modifications pathologiques du développement du testicule provoquées par la carence en biotine chez le rat. [**Pathological modifications in development of the testicle induced by biotin deficiency in the rat.**] *C.R. Soc. Biol.*, 1955, **149,** 907–910. [Lab. Physiol. Gén., Sorbonne, Paris.]

When male rats aged 1 month were given a diet without biotin and containing egg white, signs of testicular degeneration appeared within a short time. The weight of the testes was below normal from the first week and spermatogenesis was retarded, with degeneration of spermatocytes. The seminal tubules were deformed from about the seventh week of deprivation and from then until the ninth week the degeneration progressed rapidly. Rats given restricted amounts of a diet containing biotin showed no testicular abnormality.

A. M. Copping.

1758

DELOST, P. and TERROINE, T. Action inhibitrice de la carence en biotine sur le développement du tractus génital du rat mâle. [**Inhibitory effect of biotin deficiency on the development of the genital tract of the male rat.**] *C.R. Soc. Biol.*, 1955, **149,** 1236–1239. [Lab. Physiol. Gén., Sorbonne, Paris.]

The genital organs of male rats, which received for 3 months from 4 weeks of age a diet without biotin, were lighter and less well developed than those of rats having an adequate diet in restricted or unrestricted amounts. The seminal vesicles and prostate epithelium remained underdeveloped; the epididymis was almost normal. The ductus deferens was of small diameter. The mechanism of the effect is discussed.—A. M. Copping.

p-AMINOBENZOIC ACID

1759

RUSSELL, C., BHANDARI, R. R. and WALKER, T. K. **Studies of lactic acid bacteria associated with brewery products. 4. Interrelationships in requirements for purines, folic acid and *p*-aminobenzoic acid.** *J. Sci. Food Agric.*, 1955, **6,** 633–636. [Coll. Technol., Univ. Manchester.]

For previous parts see *J. Sci. Food Agric.*, 1954, **5,** 27; 1955, **6,** 133; *J. Gen. Microbiol.*, 1954, **10,** 371.

The requirements for adenine, guanine, xanthine and uracil in presence or absence of folic acid and *p*-aminobenzoic acid were estimated for 34 lactic acid bacteria isolated from beer or yeast. Uracil was necessary for 17 organisms, xanthine for none, adenine for 6 and guanine for one. The effects of folic and *p*-aminobenzoic acid varied with different strains but the requirements as ascertained existed in the presence of both these.

A. M. Copping.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

1760

MITBANDER, V. B. and SREENIVASAN, A. **Synthesis of citrovorum factor in rats given chloretone.** *Biochem. J.*, 1955, **61,** 607–610. [Dept. Chem. Technol., Univ. Bombay.]

When 20 mg. chloretone were given daily by mouth for 4 days to male rats weighing from 80 to 100 g. and having a normal diet, excretion of ascorbic acid in the urine increased and there was a slight increase in the amount in the liver. Some animals were given 4 μg. folic acid daily as well as chloretone. Folic acid and citrovorum factor increased in the liver of all rats given chloretone with or without folic acid. The extent to which folic acid was converted to citrovorum factor increased on succeeding days on which chloretone was given. The effect of the narcotic on xanthine, choline and tyrosine oxidases in the liver was to depress their activity unless folic acid was given, which was considered to be a direct effect of the narcotic on general metabolism.

A. M. Copping.

1761

DOCTOR, V. M. and TRUNNELL, J. B. **Effect of sex hormones on conversion of folic acid to citrovorum factor by rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 251–253. [Sect. Exp. Med., Univ. Texas, Houston.]

The urinary excretion of citrovorum factor estimated with *Leuconostoc citrovorum* was used as an index of its synthesis by adult male rats given a normal basal diet with a supplement of folic acid or oestradiol dipropionate or testosterone or combinations of them. Oestradiol dipropionate alone or with folic acid increased the excretion of citrovorum factor. Testosterone alone caused a decrease but had no effect on the increased excretion in response to folic acid or oestradiol.

1762

PENHOS, J. C. and FAJER, A. B. Interactions entre la somatotropine, les oestrogènes et l'acide folique chez les rats hypophysectomisés. [**Interactions between somatotropin, oestrogens and folic acid in hypophysectomised rats.**] *C.R. Soc. Biol.*, 1955, **149,** 1281–1283.

Somatotropin, oestradiol benzoate and folic acid were injected separately or in various combinations into young hypophysectomised, castrated female rats of about 90 g. weight. With oestrogen and folic acid the loss of weight was greater than in hypophysectomised rats given no vitamin or hormone. Somatotropin alone or with folic acid or oestrogen caused weight increase. Injection of oestrogen increased the weight of the uterus but decreased that of the thymus, liver and kidney. Folic acid and somatotropin had no effect on the weight of the uterus but increased that of the thymus, liver and kidney. None of the treatments affected the weight of the thyroid or adrenal glands.—A. M. Copping.

1763

MÉTAIS, P. and MANDEL, P. Action de l'acide 4-amino-ptéroylglutamique sur les acides nucléiques de la moelle osseuse du rat. Étude quantitative. [**Quantitative study of the effect of 4-aminoopteroylglutamic acid on the nucleic acids of the bone marrow in the rat.**] *C.R. Soc. Biol.*, 1955, **149,** 1022–1026. [Lab. Clin. Méd., Fac. Méd., Strasbourg.]

Doses of 10, 20, 40 or 80 μg. aminopterin daily for 3 days, or 20 μg. for 8 days, or single doses of 100 μg., were given intraperitoneally to male rats weighing about 250 g. With repeated small doses or a single large dose the deoxyribonucleic acids of the bone marrow showed a greater decrease than the ribonucleic acids. With repeated large doses both types of nucleic acid decreased. Simultaneous injection of cytosine, uracil or adenine had no effect. Large doses of folic acid, thymine and guanine were to some extent protective against the effects of aminopterin.—A. M. Copping.

1764

BALIS, M. E. and DANCIS, J. **Effects of A-methopterin on nucleic acid synthesis in leukemic spleen breis.** *Cancer Res.*, 1955, **15,** 603–608. [Labs. Sloan-Kettering Inst. Cancer Res., New York 21.]

In spleen homogenates from normal or leucaemic mice, amethopterin reduced the amount of formate incorporated into purines and thymine. The incorporation of formate and the effect of amethopterin were less in mice with leucaemia resistant to amethopterin than in those with non-resistant leucaemia.

In experiments in which the amethopterin was given to the mice 1 or 2 hr. before they were killed, there was increased synthesis of purine from formate, but reduced synthesis of thymine. The difference between the effects of amethopterin *in vivo* and *in vitro* suggested that in the body it was converted to another active substance. The independent and opposite effects on synthesis of thymine and of purines provided evidence that the routes of formation of the two substances are different.—D. Duncan.

1765

STOLYGVO, N. S. and TSIELENS, E. A. Vliyanie folievoi kisloty na rezistentnost' organizma k tuberkulezu. [**The influence of folic acid on resistance to tuberculosis.**] *Vop. Pitan.*, 1955, **14,** No. 5, 13–15. [Inst. Microbiol., Akad. Nauk Latv. SSR, Riga.]

Of 7 groups of from 12 to 26 rats weighing from 185 to 230 g., one received a stock diet and 6 a low-choline diet containing, per cent., casein 18, starch 69, soya bean oil 6, cod liver oil 1, cellulose 2 and Osborne and Mendel salt mixture 4, yeast autolysate, vitamin B_1 and riboflavin. One group had no addition, and the other 5 had, per 100 g., 50 mg. choline chloride, or 3 μg. vitamin B_{12}, or 0·5 mg. folic acid, or both vitamin B_{12} and folic acid, or fresh greenstuff. After 2 months the rats were given 3 mg. bacterial mass of bovine tubercle bacilli, and were killed from 75 to 80 days later.

Active lesions were found in 14 and healing lesions in 7 of the 17 rats on the unsupplemented low-choline diet; corresponding values were for the group on stock diet 3 and 1 out of 23, choline supplement 0 and 0 out of 26, vitamin B_{12} 12 and 6 out of 17, folic acid 2 and 0 out of 12, vitamin B_{12} and folic acid 3 and 0 out of 14, and green food 3 and 1 out of 17. The choline content of the liver was normal in all except those having the low-choline diet with and without the vitamin B_{12} supplement and these 2 were the only groups showing fatty infiltration of the liver.—D. Duncan.

VITAMIN B_{12}

1766

DROOP, M. R. **A suggested method for the assay of vitamin B_{12} in sea water.** *J. Marine Biol. Assoc. U.K.*, 1955, **34**, 435–440. [Marine Stat., Millport.]

In order to avoid the difficulty of removing salt from sea water extracts so that vitamin B_{12} could be estimated with freshwater organisms, the use of marine organisms for the purpose was investigated. *Monochrysis lutheri*, a supralittoral, euryhaline phytoflagellate, gave a reasonably sensitive response to vitamin B_{12}, though it responded also to pseudovitamin B_{12} and factor A. Its specificity in this respect resembled that of *Lactobacillus leichmannii*. It could be used to estimate vitamin B_{12} in sea water and statistical analysis of typical tests showed the suitability of the method. A disadvantage of *Monochrysis* was the length of time required for the test, since cultures required about 3 weeks to reach maturity. The amount of vitamin B_{12} found in water from incoming tides in February and March was between 5 and 10 mμg. per litre.

1767

MATSUDA, T. **Isolation of vitamin B_{12} from trichomycin fermentations.** *J. Vitaminol., Japan*, 1955, **1**, 221–228. [Govt. Indust. Res. Inst. Nagoya, Hiratemachi, Kita-ku.]

The waste liquor from fermentation by *Streptomyces hachijoensis*, used for preparation of the antibiotic trichomycin, proved a rich source of vitamin B_{12}. The original material contained 0·33 μg. per litre and 65 per cent. of it was recovered from a charcoal adsorbate. Extraction with phenol and butanol and chromatography on Amberlite IRC-50 yielded the pure vitamin, which was crystallised by addition of acetone. The final product was cyanocobalamin whether potassium cyanide was used in the extraction process or not. Absorption spectra in ultraviolet and visible light and countercurrent distribution curves were used to identify the vitamin B_{12} fractions obtained.—A. M. Copping.

1771

ANDREENKO, G. V. and KUDRYASHOV, B. A. Ismenenie tromboplasticheskoi aktivnosti krovi pri vvedenii v organizm zhivotnykh vitamina B_{12}. [**Change in the thromboplastic activity of the blood on introduction of vitamin B_{12} into the animal organism.**] *Dokl. Akad. Nauk SSSR*, 1955, **102**, 787–788.

Intraperitoneal injection of vitamin B_{12} increased thromboplastic activity in the blood of normal animals; the effect was still demonstrable after 7 days. When the injections were discontinued thromboplastic activity fell rapidly to the physiological level. It is concluded that formation of prothrombokinase as well as of platelets depends on vitamin B_{12}.—E. S. Fountain.

1772

JONES, C. C., BROWN, S. O., RICHARDSON, L. R. and SINCLAIR, J. G. **Tissue abnormalities in newborn rats from vitamin B_{12} deficient mothers.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 135–140. [Dept. Biol., Texas Agric. and Mech. Coll., Galveston.]

Female rats which had been given diets low in vitamin B_{12} weaned from 40 to 70 per cent. of their young, but normal females weaned 95 per cent. The young of deprived mothers were light in weight and immature in general development. There were abnormalities of the heart, liver, kidney and spleen. The pathological changes were prevented in young from mothers which received 25 μg. vitamin B_{12} per kg. basal diet.

1773

FERGUSON, T. M., RIGDON, R. H. and COUCH, J. R. **A pathologic study of vitamin B_{12}-deficient chick embryos.** *Arch. Pathol.*, 1955, **60**, 393–400. [Dept. Biochem. Nutrit., Agric. and Mech. Coll. Texas, College Station.]

Live embryo chicks were removed after 17 days' incubation from the eggs of hens on a normal diet or one low in vitamin B_{12} with or without a supplement of crystalline vitamin B_{12}. In 139 embryos from hens deprived of vitamin B_{12} the size was reduced and there were haemorrhages in the body cavity, heart, kidney, liver and brain, areas of necrosis in the liver, brain and spinal cord, accumulation of fat in the parenchymatous tissues and general oedema. There was gross evidence of pathological changes in 74 per cent. of the embryos from deprived hens. The significance of the observations is considered in relation to the use of vitamin B_{12} for neurological disorders.

1774

LANDBOE-CHRISTENSEN, E. and HOFF-JØRGENSEN, E. **Observations on the histo-topographic localization of the vitamin B_{12} binding factor in the fundus, pylorus and duodenum.** *Acta pathol. microbiol. scand.*, 1955, *Suppl.* 105, 104–117. [Dept. Anat., Univ. Copenhagen.]

Studies were made of post-mortem and operation material from pigs, and operation material from partial gastrectomy in man. Details are given of the methods used. Frozen material from the animals was sectioned at right angles to the surface and then separated into layers parallel to the surface, in each of which the vitamin B_{12} binding factor was estimated.

In the pig the mucosa of the fundus and pylorus and the duodenal wall all showed vitamin B_{12} binding activity, greatest in the middle layers which contained the gastric glands, the pyloric glands proper and Brunner's glands, respectively. The greatest concentration of vitamin B_{12} per mg. wet tissue was bound by the pyloric gland layer, range 29 to 43 mμg., and by the Brunner's gland layer, range 6 to 24 mμg. The cardiac mucosa showed no binding power, the superficial and deep layers of the gastric mucosa only very little, and the tunica muscularis of the duodenum none.

In man the binding activity of the mucosa was greatest in the mucosa from the fundus and lowest in the pyloric mucosa, but the highest activity found, 180 to 280 mμg. per g. wet tissue, was only about 1 per cent. of the maximum values found in material from the pig. The human material was not separated into layers. To exclude the possibility that the operative procedure might account for the low value, material from pigs was obtained by operation in the same way but showed no great reduction of binding activity.—L. Wills.

1775

WATSON, G. M. and FLOREY, H. W. **The absorption of vitamin B_{12} in gastrectomised rats.** *Brit. J. Exp. Pathol.*, 1955, **36**, 479–486. [Sir William Dunn Sch. Pathol., Oxford.]

Vitamin B_{12} containing ^{60}Co was given by mouth to normal rats and to gastrectomised rats, alone, or with an extract of rat stomach or a dialysed filtrate of pig pyloric juice. Excretion in the faeces of normal rats was on the average 66·5 per cent. of the amount given. Gastrectomised rats excreted 93·8 per cent. on the average if they had no treatment. Extract of rat stomach reduced excretion almost to normal, but results with pig pyloric juice were irregular. Most of the rats subjected to gastrectomy survived and showed good appetite and weight increase for many months after operation, but some hyperplasia and hyperkeratosis occurred in the squamous epithelium of the remnant of the stomach, and in a few animals ulcers occurred. The reasons for ulceration were not clear; mechanical irritation as well as loss of gastric secretion may have been responsible.—A. M. Copping.

1776

CHOW, B. F., QUATTLEBAUM, J. K. (Jr.) and ROSENBLUM, C. **Effect of intrinsic factor concentrate on vit. B_{12} absorption by gastrectomized rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 279–281. [Dept. Surg., Med. Sch., Johns Hopkins Univ., Baltimore, Md.]

Doses of from 50 to 200 mμg. vitamin B_{12} containing ^{60}Co were given by tube to gastrectomised rats, and the excretion of radio-active material in the faeces was used as a measure of absorption. In a second test the same dose of vitamin B_{12} was given with a concentrate of intrinsic factor and excretion of radio-activity was measured. Absorption of vitamin B_{12} by gastrectomised rats was negligible whether intrinsic factor was given or not. When intact rats were given concentrates of intrinsic factor absorption of vitamin B_{12} was inhibited in proportion to the dose of intrinsic factor.—A. M. Copping.

1777

VISTOLI, G. Sulle interazioni di alcuni aminoacidi con la vitamina B_{12} nella prevenzione della steatosi epatica dietetica del ratto. [**Interaction of some amino-acids with vitamin B_{12} in the prevention of dietary fatty liver in the rat.**] *Acta vitaminol.*, 1955, **9**, 199–204. [Lab. Provinciale Igiene.] French, English, German and Spanish summaries.

Adult male rats were given a diet of, per cent., casein 10, sucrose 59, cottonseed oil 10, lard 15, liver oil 2, salts 3, cholesterol 0·5, inositol 0·3, and vitamins except vitamin B_{12}. Three sets of 12

were divided each into 2 groups of 6 receiving subcutaneously 100 μg. vitamin B_{12} per kg. bodyweight daily or no addition ; or 10 mg. tryptophan per kg. bodyweight daily with or without the same dose of vitamin B_{12} ; or 10 mg. glycine per kg. bodyweight daily with or without the same dose of vitamin B_{12}. [The duration of the experiment is not recorded.] Histochemical examination was made of the liver for phospholipins, total and free cholesterol, glycogen and nucleic acids. It provided no evidence of lipotropic action except by tryptophan.—E. M. Hume.

1778

INFANTE, R., TURCHETTO, E. and RABBI, A. Influenza della tiroxina sulla attività lipotropa della vitamina B_{12}. [**Influence of thyroxine on the lipotropic activity of vitamin B_{12}.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 157–159. [Ist. Chim. Biol., Univ. Bologna.]

Ten groups of 5 rats weighing about 160 g. were fed for 15 days on one of 2 diets to produce a fatty liver. Two groups were given no addition, 2 were given 0·2 μg. vitamin B_{12} three times a week with 50 or 100 μg. thyroxine daily. Total fat was estimated in the liver and, in rats given no supplement, amounted to 15 or 16 g. per 100 g. fresh tissue. Vitamin B_{12} alone, in the amounts given, had no power to reduce the liver fat but when it was given with thyroxine the amount was reduced. The larger dose of vitamin B_{12} and the smaller dose of thyroxine, or the smaller dose of vitamin B_{12} and the larger dose of thyroxine, had about the same effect, reducing the percentage of fat to 11 or 12 ; with the larger doses of both substances the percentage was still lower, about 6.

E. M. Hume.

1779

PICCARDO, M. G. and SALVETTI, F. Lipotropi e metabolismo del fosforo : l'azione della vitamina B_{12} sul metabolismo del fosfato di sodio segnato con P^{32}. [**Lipotropic substances and metabolism of phosphorus: action of vitamin B_{12} on the metabolism of sodium phosphate labelled with ^{32}P.**] *Arch. Fisiol.*, 1955, **54,** 315–319. [Ist. Patol. Med., Univ. Palermo.] English summary.

Radio-active ^{32}P as Na phosphate was injected intraperitoneally into 17 rats weighing about 150 g. ; 7 of them immediately afterwards received an intraperitoneal injection of 200 μg. vitamin B_{12}. The rats were killed soon afterwards and radio-activity was estimated in the heart, liver and kidneys. In the rats given vitamin B_{12} the amount of radio-activity in the heart was nearly double that in those not given vitamin B_{12}, and in the liver it was about one-third more, but in the kidneys there was no difference.

ERICSON, L. E. and HARPER, A. E. **Effect of diet on betaine-homocysteine transmethylase of rat liver. 3. B-vitamins other than vitamin B_{12}.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 298–300. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

In order to investigate the specificity of the vitamin B_{12} requirement of the rat to maintain betaine-homocysteine transmethylase activity in the liver, the effect of withholding other members of the vitamin B complex was examined. Lack of biotin or choline caused a slight decrease of transmethylase, but an increase occurred if vitamin B_1, riboflavin, nicotinic acid, pyridoxine, pantothenic acid or folic acid was lacking. The findings are discussed with reference to other reported increases in enzyme activity in rats deprived of certain B vitamins.—A. M. Copping.

1781

SAHASHI, Y., IWAMOTO, K. and HAYASHI, J. **Effect of vitamin B_{12} on the intermediary metabolism of chicks.** *J. Vitaminol., Japan*, 1955, **1,** 312–318. [Tokyo Univ. Agric., Setagaya.]

The effect of vitamin B_{12} on enzymes containing vitamin B_1, nicotinic acid or pantothenic acid was studied in chicks depleted of vitamin B_{12}. Conjugated forms of the 3 vitamins diminished in the liver and blood of depleted chicks. In the depleted birds the vitamin B_{12} content of the liver was low but that of the blood was not less. It is considered that vitamin B_{12} is concerned in the formation of coenzymes containing vitamin B_1, nicotinic acid and pantothenic acid, and further enzyme studies are in progress.—A. M. Copping.

1782

BOXER, G. E., SHONK, C. E., GILFILLAN, E. W., EMERSON, G. A. and OGINSKY, E. L. **Changes in coenzyme A concentration during vitamin B_{12} deficiency.** *Arch. Biochem. Biophys.*, 1955, **59,** 24–32. [Res. Labs., Chem. Div., Merck and Co., Inc., Rahway, N.J.]

Coenzyme A was estimated by measurement of acetylation of sulphanilamide by aged pigeon liver and by phosphotransacetylase from *Bacterium coli*, and pyridoxal phosphate by tyrosine decarboxylase from *Streptococcus faecalis*. Rats were given diets containing only vegetable protein with or without vitamin B_{12}. In some experiments thyroid powder was included. The concentration of coenzyme A in liver and kidney in rats deprived of vitamin B_{12} was between two and three times that in non-deprived rats fed to appetite or pair-weighed. Addition of thyroid to the diet did not affect the rise in coenzyme A in deprived rats. In deprived rats there was no change in the

coenzyme A content of the brain or in the pyridoxal phosphate content of the liver. Degradation of coenzyme A proceeded at the same rate in homogenates from the liver of rats with or without vitamin B_{12}, and there was no marked difference in the oxidation of α-ketoglutarate, succinate, pyruvate or acetate by their liver and kidney homogenates.

No difference was found in the coenzyme A content of cells of *Bact. coli* grown with or without vitamin B_{12}, though the vitamin stimulated the oxidation of acetate and glutamate in the presence of deficient cells.—A. M. Copping.

1783

JOHNSON, E. L. **Turkeys require vitamin B_{12} and choline.** *Poultry Sci.*, 1955, **34**, 1013–1016. [Dept. Poultry Husb., Iowa State Coll., Ames.]

Poults hatched from the eggs of turkey hens maintained on a diet containing animal protein were given a basal all-vegetable diet. The addition to it of choline or a vitamin B_{12} concentrate improved growth up to 6 weeks of age, but not to the level of growth on a practical ration.

In a second experiment poults from hens maintained on a diet containing no animal protein were given a basal all-vegetable diet. Growth on this diet alone was poor, but was significantly increased by supplements of crystalline vitamin B_{12}. The further addition of choline did not always improve growth, but did significantly increase survival rate. A significantly greater response to supplements of vitamin B_{12} was given by poults hatched late in the season, when the parent birds had been for a long time on a vegetable diet, than by the poults of earlier hatches. It is suggested that the poult's requirement for vitamin B_{12} is not more than 3 μg. per kg. feed.—E. M. Cruickshank.

1784

JUCKER, H. Die Wirkung abgestufter vitamin B_{12}- und Antibiotika-Zulagen auf Wachstum und Futterverwertung, geprüft an Ratten und Kücken. [**Effect of graded supplements of vitamin B_{12} and antibiotics on growth and feed utilisation, tested on rats and chicks.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46**, 288–311. [Eidg. Tech. Hochsch., Zürich.] French and English summaries.

Groups of 3 male rats were given basal diets with or without animal protein and with 0, 20 or 40 μg. vitamin B_{12}, or 0, 15 or 30 mg. terramycin, per kg. diet. In some tests both vitamin B_{12} and terramycin were included. Significant increase of growth on diets containing animal protein was obtained with the higher dose of vitamin B_{12} or terramycin; the lower doses stimulated the growth of rats receiving only vegetable protein. Efficiency of feed utilisation was increased by the supplements to vegetable- but not to animal-protein diets. There was no apparent interaction between vitamin B_{12} and terramycin in rat growth tests.

In tests with chicks there were significant increases in weight gain when 20 μg. vitamin B_{12} or 20 mg. terramycin was added to a diet containing animal protein, but with a diet based on vegetable protein there was no definite effect on weight and no improvement in efficiency of feed utilisation.—A. M. Copping.

1785

ARSCOTT, G. H., SHORB, M. S. and BOGGS, U. **Effect of vitamin B_{12} and antimetabolites of vitamin B_{12} on chick hatchability.** *Poultry Sci.*, 1955, **34**, 986–988. [Dept. Poultry Husb., Univ. Maryland, College Park.]

Eggs were collected from hens maintained on a basal diet containing, per lb., 1 μg. vitamin B_{12} or none, until the hatching capacity of the fertile eggs of the hens on the diet lacking vitamin B_{12} was appreciably reduced. Injection before incubation of 0·5 or 1·0 μg. vitamin B_{12} into eggs from hens having the deficient diet improved hatching capacity to some extent, but did not restore it to normal. Fifty μg. of 1 : 2-dichloro-4 : 5-diaminobenzene, an analogue of 1 : 2-dimethyl-4 : 5-diaminobenzene, an apparent precursor of vitamin B_{12}, did not seem to affect the hatching capacity of eggs from hens deprived of vitamin B_{12}. This amount slightly decreased the hatching capacity of eggs from hens given 1 μg. vitamin B_{12} per lb. diet; 500 μg. reduced it much more. Fifty μg. of 2 : 5-dimethylbenzimidazole completely inhibited hatching of eggs lacking vitamin B_{12}, and 500 μg. depressed it considerably in eggs from hens receiving 1 μg. vitamin B_{12} per lb. diet. The results showed that analogues related to potential precursors of vitamin B_{12} may be used to study the function of the vitamin in the development of the embryo chick.—E. M. Cruickshank.

1786

RAKO, A. and ZELJKO, M. O utjecaju vitamina B_{12} i bacitracina na prirast težine prasadi. [**The effects of vitamin B_{12} and bacitracin on the growth of domestic pigs.**] *Vet. Arhiv*, 1955, **25**, 175–180. English and French summaries.

The addition of from 10 to 14 μg. vitamin B_{12} per kg. feed, alone or in combination with 5 mg. bacitracin per kg., did not improve the growth rate of pigs, regardless of the quality or quantity of protein in the ration in different experiments. (From summary.)—J. S. Thomson.

1787

ODLAND, L. M., MAYFIELD, H. L. and PAGE, L. **The influence on palatability of certain grain combinations, fish solubles and a vitamin B_{12}-aureomycin supplement in poultry rations.** *Poultry Sci.*, 1955, **34**, 822–831. [Dept. Home Econ. Res., Montana State Coll. Agric. Exp. Stat., Bozeman.]

Broad Breasted Bronze turkeys and White Leghorn and New Hampshire broilers were reared on diets containing a simple or a complex mixture of grains, or on diets supplemented with 3 per cent. fish solubles or a preparation containing vitamin B_{12} and aureomycin. The eating quality of the flesh of the roasted turkeys and the broiled chickens was tested by a panel of 10 judges. One half of each bird was cooked when fresh, the other half after storage at — 10° F. for 6 months. Methods of cooking and storage are described. When the grain portion of the ration consisted of wheat and oats or wheat and barley, the broilers were superior in eating quality to the birds receiving more complex grain mixtures of wheat, wheat products and barley, with or without maize. The reverse was true of the turkeys. The addition of fish solubles to the diet did not improve the palatability of the flesh of White Leghorn broilers, but it did increase the general desirability of both light and dark meat of turkeys and did not produce a fishy flavour in the fresh or stored meat. The addition to the diet of an antibiotic and vitamin B_{12} supplement had no effect on the quality of turkey meat, but significantly improved the tenderness and texture of the light meat of White Leghorn broilers.

E. M. Cruickshank.

1788

TARR, H. L. A. **The nutritive value of fish meal and condensed fish solubles. 10. The vitamin B_{12} content of herring stickwater and condensed solubles.** *Fish. Res. Board Canada, Progr. Rep. Pacific Coast Stat.*, 1955, No. 103, 18. [Pacific Fish. Exp. Stat.]

Vitamin B_{12} was estimated microbiologically in herring press water and condensed solubles from November to February. The values in mg. per lb. dry weight ranged from 0·42 to 0·77 for stickwater (press water) and from 0·32 to 0·55 for condensed solubles. It is calculated that 2 per cent. condensed herring solubles in a ration would satisfy the vitamin B_{12} requirement of chicks.

A. M. Copping.

1789

EVANS, R. J., BANDEMER, S. L., BAUER, D. H. and DAVIDSON, J. A. **The vitamin B_{12} content of fresh and stored shell eggs.** *Poultry Sci.*, 1955, **34**, 922–928. [Dept. Agric. Chem., Michigan State Coll., East Lansing.]

Eggs were collected from hens given a diet of maize, oats, wheat by-products, dried alfalfa, meat scraps, fishmeal, dried milk, soya bean oilmeal, minerals and vitamins A and D. They were stored at 0° C. for up to 12 months. Vitamin B_{12} was estimated in the boiled eggs by the method of Skeggs *et al.* (Abst. 1820, Vol. 20) with *L. leichmannii* as the test organism. The vitamin was liberated from the yolks and whites by autoclaving with a buffer containing sodium bisulphite. The vitamin B_{12} content of the yolks of eggs from individual hens varied considerably, from 112 to 678 millimicrograms per yolk. Fresh whole eggs contained, on the average, 387 mμg. vitamin B_{12}, of which 362 were in the yolk and 25 in the white. No change in the vitamin B_{12} content of the whites took place during 12 months' storage, but the concentration increased as the result of transfer of water from the white to the yolk. The yolks lost 34 per cent. of their original vitamin B_{12} content during 12 months' storage, mostly during the last 5 months. After 12 months' storage whole eggs contained 260 mμg. vitamin B_{12} per egg or 5·03 mμg. per g. The yolk contained 237 mμg. or 11·35 mμg. per g. and the white 23 mμg. or 0·77 mμg. per g.—E. M. Cruickshank.

1790

SREENIVASAMURTHY, V., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Vitamin B_{12} content of some animal foods.** *Indian J. Physiol. Allied Sci.*, 1955, **9**, No. 1, 33–38. [Central Food Technol. Res. Inst., Mysore.]

Vitamin B_{12} was estimated microbiologically with *Lactobacillus leichmannii* 4797 in goat and sheep muscle, goat liver, fish and eggs. Samples were autoclaved with and without cyanide for estimation of hydroxocobalamin and cyanocobalamin, and bound and free forms were estimated after digestion with papain. Goat liver was an excellent source of vitamin B_{12} with 526 mμg. per g. fresh weight, nearly all in the free form. Sheep muscle also was a good source with 300 mμg. per g., but only 94 in the free form. Hen's egg contained 104 mμg. per g. with 29 in the free form, and the values for fish ranged from 50 to 210 mμg. per g. with from 38 to 81 in the free form.

FORD, J. E. and HUTNER, S. H. **Role of vitamin B_{12} in the metabolism of microorganisms.** *Vitamins and Hormones*, 1955, **13**, 101–136. [Nat. Inst. Res. Dairying, Univ. Reading.]

OTHER B VITAMINS

1792

RABBI, A., VIVIANI, R. and MARCHETTI, M. Attività xantinossidasica del fegato di ratto carente di fattori proteici animali (FPA) della caseina. [**Xanthine oxidase activity of the liver of rats deprived of the animal-protein factor from casein.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 159–161. [Ist. Chim. Biol., Univ. Bologna.]

Xanthine oxidase was estimated by the method of Litwack *et al.* (Title 2702, Vol. 23) in the liver of rats of the first generation bred on a diet of purified casein (Abst. 3530, Vol. 21) lacking the animal-protein factor, and maintained on the diet for from 150 to 220 days. There was an increase in the amount of activity of the enzyme, which was greater the more definite the signs of deficiency. When the signs of deficiency were severe the amount of xanthine oxidase was doubled or trebled.—E. M. Hume.

1793

MERTZ, W. and SCHWARZ, K. **Impaired intravenous glucose tolerance as an early sign of dietary necrotic liver degeneration.** *Arch. Biochem. Biophys.*, 1955, **58,** 504–506. [Lab. Biochem. Nutrit., Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

Liver necrosis was produced in rats by the diet described in Abst. 464, Vol. 23. After different periods on the diet rats fasted for 18 hr. and sugar tolerance tests were made after a single intravenous injection of 125 mg. glucose per 100 g. bodyweight. When excess blood sugar was plotted against time, straight lines were obtained. From these lines was calculated the mean rate of removal of excess sugar from the blood in percentage per min. Mean rates were 4·1 in rats on stock diet and 2·8 in rats after 30 days on experimental diet. Addition of cystine to the experimental diet delayed the decline in glucose tolerance, so that it was still normal after from 25 to 30 days. Vitamin E did not prevent the decline in glucose tolerance, but factor 3 from crude casein (Abst. 464, Vol. 23) did, which is another sign that the two substances are not simple substitutes for one another.

D. Duncan.

1794

STANDERFER, S. B. and HANDLER, P. **Fatty liver induced by orotic acid feeding.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 270–271. [Dept. Biochem. Nutrit., Sch. Med., Duke Univ., Durham, N.C.]

Thirteen groups each of 10 male rats were given a diet of, per cent., casein 18, salts 5, sucrose 75 and maize oil 2, supplemented with cod liver oil, vitamin K, vitamins of the B group and sulphadiazine, without orotic acid or with 0·2, 0·5 or 1 per cent. Some groups were given supplements of folic acid, vitamin B_{12}, methionine, choline, thymine or uracil. The last two are known to be synthesised from orotic acid. The animals were killed after 28 days and liver fat was estimated. There was fatty liver when orotic acid was given, and none of the supplements prevented its appearance. Thymine and uracil did not promote it.—G. F. Garton.

VITAMIN C (ASCORBIC ACID)

1795

BARAKAT, M. Z., SHEHAB, S. K. and EL-SADR, M. M. **A new titrimetric method for the determination of ascorbic acid.** *Analyst*, 1955, **80,** 828–833. [Dept. Biochem., Fac. Med., Abbassia Ibrahim Pasha El-Kebir Univ., Cairo.]

The quantitative reduction by ascorbic acid of the orange-coloured reagent sodium 1 : 2-naphthoquinone-4-sulphonate to the colourless hydroquinone was the basis of the method. Ascorbic acid acidified with metaphosphoric acid was titrated from a microburette. Pharmaceutical products and citrus fruit juices were examined. Comparative analyses were made with the new method and that using 2 : 6-dichlorophenolindophenol. [A table suggests greater accuracy with the new method, but the authors do not make any claim.]

A. Hepburn.

BAKER, L. C., LAMPITT, L. H. and WITTENBERG, E. **Ascorbic acid. Photochemical oxidation in solutions containing oxalic acid. 1. Catalysis**

by traces of iron salts. *J. Sci. Food Agric.*, 1955, **6**, 682–688. [Lyons Labs., 149 Hammersmith Rd., London, W.14.]

Ascorbic acid in a solution containing oxalic acid and a trace of iron salt was lost when exposed to light from a mercury vapour lamp. Apparently it was oxidised to dehydroascorbic acid and diketogulonic acid. The photochemical reaction depended upon irradiation, a supply of air and a trace of iron salt. Oxidation occurred in the absence of oxalate in both darkness and light. As oxalate concentration increased the oxidation of ascorbic acid in the dark decreased to zero ; in light oxidation increased rapidly and then declined.

CURTIN, C. O. and KING, C. G. **The metabolism of ascorbic acid-1-C^{14} and oxalic acid-C^{14} in the rat.** *J. Biol. Chem.*, 1955, **216**, 539–548. [Dept. Chem., Columbia Univ., New York.]

When ascorbic acid, dehydroascorbic acid or 2 : 3-diketogulonic acid, each labelled with ^{14}C in carbon atom 1, was injected intraperitoneally into rats, 2, 9 or 12 per cent., respectively, of the radio-activity was recovered as oxalate in the urine within 24 hr. The percentages of the first two substances converted to radio-active respiratory CO_2 in 24 hr. were 19 and 29, respectively. The percentage of 2 : 3-diketogulonic acid thus converted depended on the *p*H, and was 17 at *p*H 7 and 47 at *p*H 3.

With labelled oxalate no more than 0·4 per cent. of the radio-activity was recovered as CO_2 and there was no apparent conversion to other compounds. After 10 days radio-activity was widely distributed in the tissues.

The half-life of the radio-active ascorbic acid was calculated to be 3·6 days and of oxalic acid 2·5. The rate of synthesis of ascorbic acid was calculated to be from 5 to 8 mg. daily.

WEXLER, B. C., PENCHARZ, R. and THOMAS, S. F. **Adrenal ascorbic acid and histological changes in male and female rats after half-body X-ray irradiation.** *Amer. J. Physiol.*, 1955, **183**, 71–74. [Res. Lab. Exp. Biol., Stanford Res. Inst., Calif.]

Groups of about 20 rats with the entire sagittal halves of their bodies protected by lead shields were exposed to X-rays, 625 r. They were killed from 1 to 168 hr. later. The initial depletion of ascorbic acid from the adrenal glands and its subsequent repletion which occurred after about 6 hr. was much greater than had been found after total body exposure (Abst. 584, Vol. 22). The response was more acute in the male. The adrenal gland from the shielded body half was heavier and contained more ascorbic acid than the unshielded gland. Both had qualitatively similar changes in ascorbic acid and both were shown histologically to lose lipids rapidly after treatment.

BERNARDINI, A. and CALTABIANO, S. L'azione dei raggi Roentgen sul metabolismo dell'acido ascorbico. 2. [**Action of X-rays on ascorbic acid metabolism. 2.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 293-295. [Ist. Patol., Univ. Catania.]

It was previously found (Abst. 5003, Vol. 25) that the amount of ascorbic acid in the liver, adrenal glands and spleen was greatly reduced, and that in the urine was increased, when rats were exposed to X-rays over the whole body. In the present experiment groups of 7 rats had the head only, or the thorax and abdomen, or the whole body, exposed. Others were not exposed. Fifteen days later ascorbic acid was estimated by the methylene blue method in the liver, adrenal glands, spleen and brain. Decrease in the ascorbic acid content of all the tissues was greatest when the head was the part exposed ; the effect was less when it was the whole body, and less still when it was the thorax and abdomen. There was no localisation of effect.—E. M. Hume.

1804

KLEIN, P. D., HANDA, D. T. and SWICK, R. W. **Fate of ascorbic acid in early radiation damage.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 204–208. [Argonne Nat. Lab., Div. Biol. Med. Res., Lemont, Ill.]

Ascorbic acid was estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) in organs and tissues of groups from 4 to 6 rats killed 4, 28 or 72 hr. after irradiation with X-rays, 600 r, and of rats not exposed to X-rays. The concentration and total content of ascorbic acid in the liver, brain, pancreas, kidneys, muscle, testes and brown adipose tissue was not much affected. The concentration in the thymus, lymph nodes and spleen dropped within 4 hr. and continued to drop for the remaining 68 hr. The concentration in the intestinal mucosa increased sharply during the first 4 hr. and then declined. Stimulation of ascorbic acid synthesis by chloretone did not alter

the effects, and tissue hydration could not explain them. Aminopterin produced a small rise in the concentration of ascorbic acid in the mucosa but the concentration in the lymph nodes, spleen and liver was unchanged; the changes did not reproduce those caused by exposure to X-rays.

BUTTURINI, U. and MANCINI, A. M. Azione dell'STH, dell'ACTH e del cortisone sull'acido ascorbico e suoi gruppi sulfidrilici del fegato e dei tessuti linfatici. (Ricerche istochimiche.) **[Action of STH, ACTH and cortisone on the ascorbic acid and sulphydryl groups of the liver and lymphatic tissues. Histochemical studies.]** *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 13–16. [Int. Anat., Univ. Bologna.]

Four groups including in all 34 normally fed male rats weighing from 150 to 200 g. were daily given adrenocorticotropic hormone (Ciba) 1·5 mg. by intramuscular injection for 12 days, or cortisone (Merck) 3 mg. by intramuscular injection for 15 days or 6 mg. for 5 days, or somatotropic hormone (Choay) 1·5 Evans unit by intraperitoneal injection for 10 days, or no treatment. In the liver and lymphoid tissue the distribution of vitamin C was studied histochemically by silver nitrate staining, and of protein sulphydryl groups by the histochemical method of Chevremont-Fredericq. Vitamin C could scarcely be demonstrated in the liver. In lymphoid tissue the amount was uninfluenced by adrenocorticotropic hormone; it was increased by somatotropic hormone and by the larger dose of cortisone; by the smaller dose of cortisone it was decreased. The distribution of protein sulphydryl groups in the liver and lymphoid tissue was not affected by adrenocorticotropic hormone; it was decreased by cortisone and increased by somatotropic hormone, except in the centre of the liver.—E. M. Hume.

1808

BERGERON, G. A. and BOURBEAU, G. Effets de la cortisone, de l'ACTH et de la vitamine 'C' sur l'hypertension expérimentale à la DCA. **[Effects of cortisone, of adrenocorticotropic hormone and of vitamin C on experimental hypertension produced with deoxycorticosterone acetate.]** *Laval méd.*, 1955, **20**, 465–480. [Dept. Physiol., Laval Univ., Quebec.]

One kidney was removed from 78 male rats weighing about 109 g. Five days later, in 5 groups of 15 or 16 animals, they were given deoxycorticosterone acetate (DCA), or cortisone, or both, or cortisone and vitamin C, or all 3. The mortality rate was high among the rats given DCA, the number of survivors after 21 days, in the order given above, being 10, 13, 12, 7 and 6. Cortisone and DCA, separately or together, caused severe hypertension, and vitamin C did not mitigate it. The effect of cortisone ceased when administration ceased, but that of DCA did not.

In a second similar experiment, 6 groups of from 9 to 13 rats, after removal of one kidney, received adrenocorticotropic hormone (ACTH), or ACTH and vitamin C, or ACTH and DCA, or all 3, or DCA, or no treatment. After 25 days all the rats were surviving in the 3 groups not receiving DCA, but of those given DCA, whether alone or not, only 4, 4 and 5 survived. ACTH had no effect on blood pressure and, with or without vitamin C, did not counteract the effect of DCA.

BACCHUS, H. and LAMPKIN, J. M. **Influence of citric acid cycle intermediates on the *in vitro* metabolism of corticosteroids in ascorbic acid deficiency.** *Endocrinology*, 1955, **57**, 531–540. [Endocrine Lab., Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

Liver slices from guineapigs fed on a scorbutogenic diet for up to 24 days metabolised the 17-hydroxy-20 : 21-ketol side chain of cortisone *in vitro* to a greater extent than slices of normal liver. After from 31 to 36 days of the diet, when the animals were moribund, the ability decreased. Pyruvate, α-ketoglutarate, citrate, ascorbate or, to a less extent, oxaloacetate, could prevent the increase, but succinate, fumarate and malate had no effect. All the 3 last substances and oxaloacetate could increase the metabolism of the side chain of cortisone by normal liver slices, but the others had no effect. Rinsing or storing liver in cold buffer solution tended to abolish the metabolic differences between the livers of normal guineapigs and of those deprived of ascorbic acid.

[**Metabolism of the adrenal cortex and biosynthesis of corticosteroids. 9. Further contribution on the mode of action of ascorbic acid.**] *Biochem. Ztschr.*, 1955, **327**, 284–291. [Zentrallab., Städt. Krankenanst., Mannheim.]

Dehydroascorbic acid was reduced to ascorbic acid by a homogenate of whole adrenal gland, but not by adrenal mitochondria. Ascorbic acid, but not dehydroascorbic acid, at *p*H 6·6 activated 11 β-oxidation of deoxycorticosterone by isolated mitochondria from pig adrenal glands, and the action was increased by ultraviolet light. Ultraviolet light activated total corticosteroid synthesis by adrenal homogenates in the presence of ascorbic acid.

It is concluded that ultraviolet light favours the formation of an active form of ascorbic acid, which influences the transport of hydrogen or electrons in the adrenal cell.—D. Duncan.

Reply to an abstractor's criticism of a method for adding ascorbic acid to butter described by the author in a paper with the above title (*Milchwissenschaft*, 1953, **8**, 300).—W. M. Deans.

1817

GUTHRIE, E. S. **Role of ascorbic acid in development of oxidized flavors in dairy products.** *Cornell Univ. Agric. Exp. Stat. Memoir* No. 340, June 1955, pp. 56.

Experiments over several years confirmed the theory of Krukovsky and Guthrie (Abst. 2059, Vol. 15) that oxidation of ascorbic acid is the most important cause of oxidised flavour in milk. Contributory causes are light, homogenisation, presence of metals, especially copper, oxygen and high temperature.

Pasteurisation for 30 min. caused less oxidation of ascorbic acid at 165° F. than at 143° F. and

oxidised flavour did not develop so readily. Fresh concentrated milk kept a fresh flavour longer than ordinary milk. Of 18 cows, 1 consistently gave milk susceptible to oxidation and 4 always gave non-susceptible milk; the milk from the other cows varied. Intensity of oxidised flavour was slightly greater in winter than in summer. Ascorbic acid had disappeared from the pasteurised milks of 5 cows after 7 days' storage but was still found in 5 other milks after 28 days.

Washing cream with warm water removed ascorbic acid and improved the keeping quality.

Milk exposed to daylight developed oxidised flavour which was greater when the milk had previously been homogenised. Amber bottles partly protected the milk even when homogenised. The worst flavour was found in cream.

An extensive review of the literature is given.

HOOVER, M. W. **Influence of maturity and storage treatments upon the ascorbic acid content of the seeds of Southern peas.** *Food Res.*, 1955, **20,** 469–473. [Univ. Florida Agric. Exp. Stat., Gainesville.]

Three types of Southern pea were harvested at 6 different stages of maturity, the first stage being as early as the seeds could be separated from the pericarp, about 10 days after flowering, and at 2-day intervals afterwards. Storage temperatures were 40°, 70 and 100° F. and samples were analysed fresh and after storage for 24, 48 and 72 hr. Vitamin C was estimated by the indophenol method.

At the earliest stage of maturity the peas contained from 51 to 58 mg. ascorbic acid per 100 g. fresh weight, the value falling gradually to from 7 to 15 mg. at the 6th stage of maturity. Peas at the 4th stage of maturity, containing about 32 mg. per 100 g. fresh weight, lost very little ascorbic acid when stored at 40° F. for 72 hr. but when the storage temperature was 100° F. the loss was 54 per cent.—J. S. Thomson.

LANG, K. and WEYLAND, H. Über den Stoffwechsel des Rutins und Quercetins. [**Metabolism of rutin and quercetin.**] *Biochem. Ztschr.*, 1955, **327,** 109–117. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

The metabolism of rutin and of quercetin was studied manometrically in the presence of liver and kidney preparations from rats, and with cyclophorase systems from brain, muscle and heart. Breakdown of the flavonols seemed to be closely associated with cyclophorase systems in all tissues. The most active enzyme was present in liver and kidney; those of brain, heart and muscle were less active. The breakdown appeared to be rapid and no intermediary product was identified.

When doses of from 0·2 to 2·0 g. rutin or quercetin per kg. bodyweight were given by mouth or parenterally to rats or rabbits, only very small quantities were excreted unchanged in the urine. There was no increase of phenols or keto-acids in the urine of animals receiving large doses of rutin or quercetin.—A. M. Copping.

1822

D'AMICO, G. Intorno all'azione della vitamina P sulle lesioni gastriche da acido fenilchinolincarbonico. [**Action of vitamin P on gastric lesions caused by phenylquinolinecarbonic acid.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 385–386. [Ist. Clin. Chirurg., Univ. Messina.]

Of 2 groups of 6 dogs given daily 0·25 g. Atophan (phenylquinolinecarbonic acid) per kg. bodyweight, I received in addition 2 daily intramuscular injections of vitamin P. Three dogs died; the rest were killed after 6 or 20 days. The incidence of gastric haemorrhage and ulcers was the same in the 2 groups.—E. M. Hume.

1823

SCHÄFER, E. and GREUEL, H. Der Einfluss des Rutins auf den Verlauf der experimentellen Meerschweinchentuberkulose. [**Influence of rutin on the course of experimental tuberculosis in the guineapig.**] *Ztschr. Tuberkulose*, 1955, **106,** 238–244. [1. Med. Klin., Med. Akad., Düsseldorf.]

In tests with 97 guineapigs, 25 mg. rutin every second or third day had no effect on survival time or severity of lesions after infection with tuberculosis. There appeared to be a slight retardation in the development of the tuberculous process in animals receiving rutin, but the results of the tests did not justify the recommendation of rutin for treating tuberculosis in man.—A. M. Copping.

Kozov., Stavropol.]

Studies on the pancreatic juice of sheep showed that the concentration of lipolytic, proteolytic and carbohydrate-splitting enzymes depended on the diet. The *p*H of the juice varied from 6·52 to 6·90. Adaptation of secretion, especially of proteolytic enzymes, to a change in diet was better when the change was gradual.—D. W. Taylor.

1828

BARRETT, J. L., NISHIKAWARA, M. T. and HAIST, R. E. **Effects of hypophysectomy and of undernutrition on amylolytic activity of the pancreas of the rat.** *Amer. J. Physiol.*, 1955, **182,** 35–38. [Dept. Physiol., Univ. Toronto.]

Unoperated control rats were given the amount of food eaten by pair-fed rats of both sexes with pituitaries removed. The diets were either ground fox ration or a mixture of dog food, bread, milk and sucrose.

Operated rats failed to grow, controls grew slightly. The activity of pancreatic amylase per g. pancreas or per mg. N was reduced by removal of the pituitary, and absolute activity was even less because the pancreas was small. In young rats, fasting reduced the size of the pancreas, but not its amylolytic activity per g. tissue. Restriction of food so as just to permit normal rats to maintain bodyweight did not reduce amylase activity per g. pancreas.

It is concluded that loss of amylase activity after removal of the pituitary cannot be ascribed solely to undernutrition.—D. Duncan.

1829

HOLZER, H., GOEDDE, H. W. and SCHNEIDER, S. Umsatz von Oxybrenztraubensäure und Glykolaldehyd mit Carboxylase und Alkoholdehydrase aus Hefe. [**Conversion of hydroxypyruvic acid and glycolaldehyde with carboxylase and alcohol dehydrase from yeast.**] *Biochem. Ztschr.*, 1955, **327**, 245–254. [Physiol. Chem. Inst., Univ. Hamburg.]

Purified carboxylase from brewer's yeast decarboxylated both pyruvate and hydroxypyruvate. The relative rates of reaction were 76 : 1. Breakdown of pyruvate and hydroxypyruvate in the presence of carboxylase could be calculated from the rate of loss of substrate as estimated with lactic dehydrase; breakdown of pyruvate was quicker, but separation of the two substances on this basis was impossible. Hydroxypyruvate inhibited decarboxylation of pyruvate, and it probably regulates carbohydrate metabolism by this competition for carboxylase. The product of decarboxylation of hydroxypyruvic acid was glycolaldehyde, which was reversibly converted to ethylene glycol by alcohol dehydrase and reduced diphosphopyridine nucleotide. This provided an optical test for the rate of decarboxylation of hydroxypyruvate.—D. Duncan.

EMANUELSSON, H. **Changes in the proteolytic enzymes of the yolk in the developing hen's egg.** *Acta physiol. scand.*, 1955, **34**, 124–134. [Dept. Zoophysiol., Univ. Lund.]

In the yolks of hen's eggs after different periods of incubation, measurements were made of free amino-acids by chromatographic methods and of enzyme activity by proteolytic action on a solution of Hb. No evidence of change in the amounts of amino-acids or of peptides soluble in alcohol was found. Activity was, in the main, referable to 3 enzymes with optimum *p*H values of 3, 5 and 7. The concentration of the first was doubled in the first day of incubation, then fell and later rose; its lowest concentration on the ninth day was still well above that in the unincubated egg. The second and third enzymes also increased during incubation, but did not reach their maximum activities until the ninth day.

The findings are discussed with reference to the view that the first enzyme reaches the yolk by diffusion from the embryo and that the others are liberated in the yolk during incubation.

D. Harvey.

1833

LANG, K. and KELLER, C. Die Einwirkung des Cyclophorase-Systems auf die schwefelhaltigen Aminosäuren. [**Effect of the cyclophorase system on the sulphur amino-acids.**] *Biochem. Ztschr.*, 1955, **327**, 202–208. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

The cyclophorase system was prepared from rat liver or kidney by the method of Green *et al.* (*J. Biol. Chem.*, 1948, **172**, 389). It was found to deaminate DL-methionine to α-keto-γ-hydroxymethylbutyric acid and α-keto-γ-thiomethylbutyric acid; to oxidise L-cysteine to L-cystine; to oxidise DL-homocysteine to DL-homocystine and also to deaminate 10 to 15 per cent. of it; and to attack cystathionine. In the last-named reaction oxidative deamination occurred, but there was more uptake of oxygen and less production of keto-acids than would be expected on theoretical grounds. It is concluded that the cystathionine was attacked by thionase and that the products were deaminated or were oxidised to disulphides.

The interpretation of the results is discussed.

D. Duncan.

ESTES, F. L., WAINIO, W. W. and ALLISON, J. B. **Effect of limitation of protein intake on hepatic uricase and on urinary uric acid and allantoin.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 619–621. [Dept. Chem., Douglass Coll., New Brunswick, N.J.]

The 3 groups of rats were as described in Abst. 4431, Vol. 23. When they were killed the livers were removed for estimation of uricase activity. Urine samples were collected during each 3-day period of the experiment and pooled for estimation of allantoin and uric acid.

The uricase activity in the livers of the rats on the protein-free diet was lower than that in the livers of the other 2 groups; the fall was not

accompanied by an increase in the uric acid : allantoin ratio in the urine. The allantoin or the uric acid content of the urine and the uricase content of the liver followed the same trend.

BAMANN, E. and RIEHL, J. Zur Frage der Co-Existenz einer Phospho-mono- und -di-esterase. 1. Mitteilung zur Spezifität der Phosphatase. [**Co-existence of phospho-mono- and -di-esterase. 1. Specificity of phosphatase.**] *Biochem. Ztschr.*, 1955, **327,** 136–148. [Inst. Pharm., Univ. Munich.]

The aromatic ester monophenylphosphoric acid is more readily hydrolysed than the aliphatic phosphoric mono-esters of methyl, ethyl, *n*-propyl and *n*-butyl alcohols, whether by acid or alkaline phosphatases from cattle or pig liver or from potato. This difference is related to a slightly greater rate of splitting of intermediary products of monophenylphosphoric acid. The susceptibility of the aliphatic esters increases with the chain length of the alcohol residue, which is related to the simultaneous increase of the affinity of the substrate for the enzymes and increase in the rate of splitting of intermediary products in the series from monomethyl- to mono-*n*-butylphosphoric acid.

Dimethyl- and diethylphosphoric acid are not attacked by animal or plant phosphatases. Di-*n*-butyl- and diphenylphosphoric acid are attacked by animal phosphatases, but not by those of potato or *Aspergillus oryzae*. This demonstrates that it is possible for the same enzyme to hydrolyse both mono-esters and di-esters.—D. Duncan.

DIGESTION AND ABSORPTION

1837

ADAM, A. and CZECH, E. Die Magenverdauung der homogenisierten Milch beim Säugling. [**Gastric digestion of homogenised milk by infants.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 361–365. [Kinderklin., Univ. Erlangen.]

After a test feed of homogenised milk 15 healthy infants secreted less gastric juice than after a similar feed of untreated milk. In 3 infants with digestive disturbances this difference disappeared. Experiments *in vitro* showed that the homogenising process increased the rate of breakdown of the carbohydrate and fat of milk by the gastric and intestinal enzymes, and the finding was thought to explain the smaller secretion of gastric juice after homogenised than after untreated milk.—L. Wills.

CZOK, G. and LANG, K. Wirkungsunterschiede zwischen gefiltertem und ungefiltertem Bohnenkaffee. [**Differences in effect between filtered and unfiltered coffee.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1641–1642. [Physiol. Chem. Inst., Univ. Mainz.]

Coffee made by pouring boiling water on ground coffee, allowing it to stand and carefully pouring it off raised total acidity and free HCl in the gastric juice of 12 healthy subjects much less than coffee prepared with "Melitta" filters. The difference is probably due to the removal of tannins by filtration. Unfiltered coffee had a significantly greater effect in increasing the activity and reducing the electroshock threshold of rats given per kg. bodyweight 5 ml. of an infusion made from 10 g. ground coffee and 200 ml. water.

JAVID, H. **Nutrition in gastric surgery with particular reference to nitrogen and fat assimilation.** *Surgery*, 1955, **38,** 641–651. [Dept. Surg., Univ. Illinois Coll. Med., Chicago.]

Dogs were given a diet supplying daily 80 Cal., 5 g. protein and 4 g. fat per kg. bodyweight. After studies of excretion of N and fat in faeces they underwent, in groups of 6, vagotomy alone, gastroenterostomy without or with vagotomy, or partial gastrectomy without or with vagotomy, with removal of two-thirds of the stomach. The studies of excretion were repeated at intervals of from 6 weeks to 6 months after the operations.

The effects of the operations in the above order were : none ; none ; increase in fat with no change in N excretion ; significant increases in excretions of both fat and N ; increases in excretions which were, on the average, still greater than those after gastrectomy without vagotomy. From the limited set of studies, gastroenterostomy with vagotomy is thought to be less harmful nutritionally than gastrectomy.—D. Harvey.

PONZ, F. and QUERALTÓ, M. R. Paso de compuestos de fósforo de la mucosa a la luz del intestino durante la absorción de azúcares. [**Passage of phosphorus compounds from the mucosa to the lumen of the intestine during the absorption of sugars.**] *Rev. española Fisiol.*, 1955, **11**, 105–141. [Lab. Fisiol. Animal, Fac. Cienc., Univ. Barcelona.] English summary.

The methods for estimation of P fractions are described in detail. The technique of Sols and Ponz (Abst. 3357, Vol. 17) was used to study absorption in rats of 60 to 180 g. bodyweight. The amounts of total, inorganic, ester and lipid P secreted into the intestine were estimated after 15, 30, 45 and 60 min. during absorption of glucose from hypotonic, isotonic and hypertonic solutions, during absorption of arabinose and after withdrawal of glucose solutions.

The secretion of inorganic P increased with the concentration of the glucose solution. A peak of concentration in the lumen was reached after 45 min. Ester P secretion fell as glucose concentration rose, but the total rate of secretion increased through the 60 min. of experiments. Lipid P concentration in the intestinal lumen increased steadily during glucose absorption from isotonic or hypotonic but not from hypertonic solutions. The peak of total P in the intestinal lumen was reached after 45 min. of glucose absorption and after this some P was re-absorbed. Results with arabinose were similar to those with glucose. Secretion of P into the intestine persisted at a reduced rate during 30-min. experiments after glucose had been replaced by isotonic NaCl solution.

Isotonic NaCl solution did not provoke secretion of P, nor did glycine. Secretion in response to glucose was inhibited by phloridzin or uranyl, but iodoacetate inhibited only the secretion of lipid P.

The mechanisms involved are discussed.

The presence of K in solutions introduced into segments of the ileum of rats reduced the quantity of glucose absorbed. This effect was not found in the colon.—A. T. Phillipson.

1843

ESCRIBANO, J. and PONZ, F. Nuevos inhibidores enzimáticos que afectan a la absorción intestinal de glucosa. [**New enzyme-inhibitors which affect absorption of glucose from the intestine.**] *Rev. española Fisiol.*, 1955, **11**, 153–180. [Lab. Fisiol. Animal, Fac. Cienc., Barcelona.] English summary.

Absorption of glucose in isotonic solutions, 5·4 per cent., was studied in experiments on rats by the Sols and Ponz technique (Abst. 3357, Vol. 17). Tests lasted 30 min., and in 4 successive tests on each rat absorption was studied of glucose alone, glucose with an inhibitor, glucose alone and glucose with the inhibitor again.

Atebrine inhibited absorption at concentrations of 9×10^{-4} *M* or more, and the inhibition was not reversible. Chloral hydrate inhibited, also irreversibly, at from 5×10^{-2} to 10^{-1} *M*. Neosalvarsan caused 20 per cent. inhibition at 10^{-3} *M* and 80 per cent. inhibition at $4{\cdot}3 \times 10^{-3}$ *M*, again irreversible. Triethylene melamine produced irreversible inhibition at between $7{\cdot}4 \times 10^{-4}$ *M* and 3×10^{-3} *M*. All the inhibitors had local action. Phenylacetic acid inhibited only in very concentrated solution, sulphaguanidine and sulphanilamide not at all. Sodium malonate produced 10 to 15 per cent. inhibition at 10^{-2} *M*, showing that succinic dehydrase is of importance for active transport of glucose.

The interpretation of the findings in terms of the mechanism of active transport of glucose is discussed.—D. Duncan.

1844

STERN, P., HUKOVIĆ, S. and FUKAREK, V. Über die Resorption der Kohlehydrate aus dem sterilen Darmkanal des Kaninchens. [**Absorption of carbohydrates from the sterile intestine of the rabbit.**] *Gastroenterologia*, 1955, **83**, 349–353. [Pharmakol. Inst., Med. Fak., Sarajevo.] English and French summaries.

Rabbits were given terramycin and penicillin for 5 or 6 days as described in Abst. 890, Vol. 25, until the faeces were bacteriologically negative except for *Proteus vulgaris*. Absorption of carbohydrate was estimated by a study of the blood sugar after administration by mouth of 20 ml. of 20 per cent. glucose solution, or starch in the form of oats to appetite.

Sugar was absorbed normally from the sterile intestine, but there was no increase in the blood sugar 4 hr. after the starch meal. The diastase activity of the gut wall was normal. It is concluded that starch breakdown in the normal rabbit depends on bacterial activity.—D. Duncan.

1845

PORTMAN, O. W., MANN, G. V. and WYSOCKI, A. P. **Bile acid excretion by the rat : nutritional effects.** *Arch. Biochem. Biophys.*, 1955, **59**, 224–232. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Bile acids were prepared from rat bile and estimated spectrophotometrically by a method similar to that described in Abst. 1894, Vol. 26. The adult rats were given a basal diet with, per cent., casein 25, fat 8, carbohydrate 57·6 and Cellu flour 5, minerals and vitamins, at the rate of 4 g. protein and 64 Cal. daily. Groups of from 4 to 10 rats received this diet or modifications of it or commercial Purina chow for 15 days and then their bile ducts were cannulated and bile was collected for 24 hr.

Rats on Purina chow excreted more total bile acids and a higher proportion of cholic acid than those on the synthetic diets. On both chow and basal diets, 5 per cent. cholesterol significantly increased bile acid and cholesterol output. Raising the maize oil from 8 to 15 per cent. had no effect on bile acids or cholesterol. Substitution of egg albumin for casein increased bile acid output, but addition of methionine, cystine or taurine to the casein diet did not. There was no significant effect of supplements of dried liver or brewer's yeast or of vitamin B_{12} given intraperitoneally. When rats previously fed on chow were fasted for 24 hr. before cannulation and during the collection of bile they excreted less bile acid than those fed on chow; but with rats on the basal diet fasting increased output of bile acids. When starch was given instead of sucrose there was a larger excretion of bile acids and a larger proportion of cholic acid, but dextrose had not this effect. An increase of Cellu flour from 5 to 20 per cent. also increased the output of bile acids and cholic acid.

It was concluded that sucrose and dextrose inhibit excretion of bile acids in the rat.

Clément, G., Clément, J., Drevet, M. and Abadie-Debat, J. Sur le mécanisme chimique de l'hydrolyse enzymatique des huiles et graisses naturelles. 2. Études des constituants lipidiques du contenu intestinal du rat après administration d'huiles ou de graisses diversement saturées. Influence de suc pancréatique et de la bile. [**Chemical mechanism of the enzymic hydrolysis of natural oils and fats. 2. The lipid constituents of the intestinal contents of the rat after oils or fats of differing saturation. Effect of pancreatic juice and bile.**] *Bull. Soc. Chim. biol.*, 1955, **37**, 857–865. [Inst. Res. Sci. Cancer, C.N.R.S., Paris.]

For part 1 see Abst. 3665, Vol. 25.

Normal rats and rats with bile and pancreatic duct fistulae were given 1 ml. fat or fatty acids by stomach tube and were killed 3 hr. later. Total lipids were extracted from intestinal contents and fractionated into free fatty acids, soaps, glycerides and phospholipins, the I value of each of which was estimated. The fats used included soya bean oil, linseed oil, mutton fat and karite butter [shea butter, *Butyrospermum parkii*].

It was concluded that the course of intestinal hydrolysis of fats involved the formation of fatty acids and soaps of lower I value than that of the remaining glycerides and that intestinal enzymic hydrolysis preferentially removed the more saturated fatty acids from a fat. Formation of phospholipins was favoured by administration of unsaturated fat, but not of saturated fat.

G. A. Garton.

1847

Blomstrand, R. **The intestinal absorption of phospholipids in the rat.** *Acta physiol. scand.*, 1955, **34**, 147–161. [Dept. Physiol. Chem., Univ. Lund.]

Phospholipins labelled with oleic acid-1-^{14}C, palmitic acid-1-^{14}C and ^{14}C-labelled glycerol, or palmitic acid-1-^{14}C and ^{32}P were given by stomach tube to rats with thoracic duct fistulae. Lymph was collected for 24 hr. and its lipids were fractionated into neutral fat and phospholipins for measurement of their radio-activity.

Most of the ^{14}C activity in the lymph lipids was associated with the glyceride fraction, a significantly greater proportion of the radio-activity than was found in earlier experiments when the labelled fatty acids were given free or in glyceride combination.

The data indicated that there was extensive hydrolysis of ingested phospholipins in the intestine and that a small amount of glyceride glycerol was derived from the phospholipin glycerol, suggesting synthesis from a mono- or di-glyceride. The relative specific activity of lymph phospholipin glycerol was about 30 per cent., suggesting that there had been direct absorption of unchanged phospholipin; the experiment with ^{32}P-labelled phospholipin supported this hypothesis.

Ivy, A. C., Lin, T. M. and Karvinen, E. **Absorption of dihydrocholesterol and soya sterols by the rat's intestine.** *Amer. J. Physiol.*, 1955, **183**, 79–85. [Dept. Clin. Sci., Univ. Illinois Coll. Med., Chicago.]

Balance studies showed that rats had a limited capacity to absorb cholesterol from the diet, about 92 mg. per 250 g. rat or 370 mg. per kg. bodyweight daily. Excess amounts of sterols which do not give the Liebermann Burchardt reaction were not excreted until cholesterol was given in excess of the animals' capacity for intestinal absorption. When 192 mg. dihydrocholesterol or soya bean sterols (93 per cent. sitosterols) was given to rats weighing 200 to 250 g. about 22 per cent. was absorbed. When 192 mg. dihydrocholesterol and 96 mg. cholesterol were given together, 18 and 36 per cent., respectively, was

absorbed. When 96 mg. cholesterol was given alone, 61 per cent. was absorbed, so the dihydrocholesterol reduced absorption of cholesterol by about 40 per cent. Soya bean sterols similarly affected the absorption of cholesterol from the diet.

It is suggested that dihydrocholesterol and soya bean sterols decrease absorption of cholesterol by competing for the total absorptive capacity.

GRIM, E., LEE, J. S. and VISSCHER, M. B. **Water exchange between intestinal contents, tissues and blood.** *Amer. J. Physiol.*, 1955, **182,** 359–363. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

In dogs cannulae were inserted at the ends of a loop, about 20 cm. in length, of the lower ileum, and the loop was perfused with fluid containing D_2O. Blood samples for analysis were withdrawn from the mesenteric vein draining the loop; in some experiments the loop was excised and the mucosal and muscular layers were separated and analysed.

The concentration of D_2O in the mucosal tissue was never, even after lavage for 2 hr., more than 25 per cent. and in the mixed venous blood never more than 5 per cent. of the concentration in the perfusing fluid.

Possible explanations are discussed.

D. Harvey.

1851

DOUGHERTY, R. W. and HABEL, R. E. **The cranial esophageal sphincter, its action and its relation to eructation in sheep as determined by cinefluorography.** *Cornell Vet.*, 1955, **45,** 459–464. [New York State Vet. Coll., Ithaca.]

The activity of the cranial oesophageal sphincter was studied in 6 lambs of 45 to 60 lb. liveweight, after a mixture of CO_2 and methane had been insufflated through a rumen cannula to stimulate eructation. The cranial sphincter remained tightly closed except during swallowing and eructation. It did not open when the rumen and oesophagus were forcibly filled with warm water and ingesta to a pressure of 40 mm. Hg, which overcame the resistance of the cardial and diaphragmatic sphincters. The process of eructation is described.

D. Duncan.

1852

DZIUK, H. E. and SELLERS, A. F. **Physiological studies of the vagal nerve supply to the bovine stomach. 2. Studies on the eructation mechanism in adult cattle.** *Amer. J. Vet. Res.*, 1955, **16,** 499–504. [Div. Vet. Physiol. Pharmacol., Sch. Vet. Med., St. Paul, Minn.]

For part 1 see Abst. 526, Vol. 26.

In 3 cows with rumen fistulae electrodes were applied to the dorsal vagal trunk in the thorax. Studies of responses to stimulation could be made for from 3 to 6 months after operation. Movements of the rumen, reticulum and cardia were recorded by pressure changes.

In all 3 cows stimuli at a frequency of 10 cycles per sec., 5 millisec. pulse duration and 10 volts applied for 2 to 5 min. caused increased rumen movements and about doubled the frequency of eructation when air was insufflated into the rumen at constant rate. Stronger stimuli, either of greater frequency or higher voltage, produced spasmodic contractions of rumen, reticulum and cardia. Even when the rumen contained much water and the cow's hindquarters were raised to submerge the cardia, eructation occurred regularly and was increased by vagal stimulation.

D. Duncan.

1853

WILLIAMS, E. I. **A study of reticulo-ruminal motility in adult cattle in relation to bloat and traumatic reticulitis with an account of the latter condition as seen in a general practice. 1. A study of reticulo-ruminal motility in adult cattle with reference to the eructation of ruminal gases and bloat. 2. A survey of sixty-four cases of traumatic reticulitis diagnosed by the "reticular grunt" method.** *Vet. Rec.*, 1955, **67,** 907–911; 922–927. [St. Clears, Carms, S. Wales.]

1. Reticulo-ruminal motility was studied in 400 normal adult cattle by combined palpation with the hand in the left iliac fossa and auscultation with the stethoscope placed at the costochondral junction of the left seventh rib. A remarkably constant cycle of movement is described. Belching usually accompanied those rumen contractions which occurred without contraction of the reticulum. The rhythm of primary reticulo-ruminal contractions and extra ruminal contractions was 1 : 1 in 295 animals, 2 : 1 in 64 and 1 : 2 in 41. The 2 : 1 rhythm was mostly found with relatively empty stomachs.

Movements were studied also in the course of rumenotomy operations on 69 animals, 64 of them for traumatic reticulitis. In all the cattle with reticulitis there was a 1 : 1 rhythm of contractions. Eructation did not accompany the extra ruminal contraction unless the incision was sealed round the operator's arm with cotton-wool. In the 2

animals with frothy bloat the extra ruminal contractions were absent, but the primary contractions were particularly forceful. The cardia was normally closed, and was opened by contraction of the dorsal sac. Massage in the region of the reticulo-ruminal fold sometimes initiated regurgitation.

The mechanism of eructation is discussed.

2. Diagnosis of traumatic reticulitis from a grunt accompanying reticular contraction was extremely reliable. In most animals the grunt occurred during the phase of reticular relaxation and contraction of the dorsal ruminal sac.

D. Duncan.

1854

POUNDEN, W. D., HIBBS, J. W. and CONRAD, H. R. **Rumen content in young calves.** *Vet. Med.*, 1955, **50,** 435–440. [Dept. Vet. Sci., Ohio Agric. Exp. Stat., Wooster.]

Fluid was removed by stomach tube from the rumens of young Jersey and Holstein calves. In Jerseys there was an increase between the eighth and tenth days of life, and then the quantity gradually fell. In Holsteins there was an increase between the sixth and ninth days, a fall and then another increase between the tenth and thirteenth days, and then a tailing-off.

During the first day of life there was milk in the rumens of more than half the calves examined. From 1 to 9 days old milk was present in only a quarter of the animals. For the next 20 days milk or curd was found in one in 8 calves getting concentrates and hay, and in one in 30 getting only hay as dry feed. At post-mortem examination fibre- and hairballs were found in fewer calves under 10 or over 21 days old than in those between these ages.

The average *p*H of rumen contents of calves under 10 days old was 6·83 with range 5·97 to 7·60 in those with no milk present. When milk was present the *p*H was lower, 4·43 to 6·27, average 5·42. From calves aged from 11 to 25 days getting grain and hay to appetite the *p*H was 6·69, and in those getting only milk was 6·50.

The importance of giving roughage at an early age is discussed.—T. D. Bell.

1855

LAMPILA, M. **Preliminary studies on the variations of pH and volatile fatty acid concentration of the rumen contents of the cow.** *Maataloust. Aikakausk.*, 1955, **27,** 142–153. [Agric. Res. Centre, Dept. Animal Husb., Tikkurila, Finland.] Finnish summary.

Measurements were made of the *p*H at different levels in the rumen of a cow with a fistula, and samples of contents were taken from neighbouring points for estimation of volatile fatty acids. Observations were made with 5 different diets during stall feeding, and at pasture.

The *p*H changes in the course of the day were negligible when the cow was at pasture. Their rate and extent during stall feeding depended on the ration. The lowest *p*H was always in the uppermost part of the rumen and the highest *p*H at the bottom. The greatest changes occurred in the upper part. The low *p*H in the upper part was related to a higher concentration of volatile fatty acids, at times as much as 50 per cent. more than in the lower parts. The *p*H values measured *in vitro* were from 0·15 to 0·65 units higher than those *in vivo*.

1856

CUNNINGHAM, H. M. and BRISSON, G. J. **Note on alcoholic fermentation in the stomachs of lambs fed high-glucose diets.** *Canad. J. Agric. Sci.*, 1955, **35,** 511–512. [Div. Chem., Sci. Serv., Canada Dept. Agric., Ottawa.]

Signs of alcoholic intoxication were seen in lambs fed on a fat-free high-glucose diet. The stomach contents smelt of alcohol and concentrations up to 0·62 per cent. were found. Alcohol was present in the blood and urine. Alcohol was not detected when the carbohydrate of the diet was lactose.

The signs of intoxication in lambs given absolute alcohol at the rate of 5 to 10 ml. per kg. bodyweight were identical with those seen after the high-glucose diet.—A. T. Phillipson.

1857

RAYNAUD, P. Diverses formes d'azote dans les réservoirs digestifs des bovidés. [**Different forms of nitrogen in the digestive tract of cattle.**] *Arch. Sci. physiol.*, 1955, **9,** 83–96. [Labs. Physiol., Fac. Sci., Toulouse.]

See also Abst. 3655, Vol. 25.

The N content of material from the rumen, abomasum and duodenum of cattle was divided into protein, ammonia, polypeptide and residual, mainly mono-amino-, fractions.

Protein N increases from rumen to duodenum, but forms a decreasing proportion of the total N. Ammonia N is lowest in the abomasum, high in rumen and duodenum. Polypeptide N increases from rumen to duodenum, and forms its highest proportion of the soluble N in the abomasum. Residual N is almost absent in the rumen, unimportant in the abomasum, but rises to a mean of 17 per cent. of the total and 42 per cent. of the soluble N in the duodenum. Thus there seems to be little digestion of polypeptides in the stomach, such as there is in non-ruminants.—D. Duncan.

1858

LEWIS, D. **Amino-acid metabolism in the rumen of the sheep.** *Brit. J. Nutrition*, 1955, **9,** 215–230. [Agric. Res. Counc. Inst. Animal Physiol., Babraham, Cambridge.]

Amino-nitrogen was estimated in the rumen liquor after concentration at *p*H 9 *in vacuo*. The quantities found ranged from 0·1 to 1·4 mg. per 100 ml. The principal acids present were glycine, alanine, valine, glutamic acid and proline. Individual amino-acids introduced into the rumen gave rise to ammonia. Washed suspensions of rumen bacteria deaminised mixtures of amino-acids more rapidly than individual acids. Of the acids tested individually, aspartic acid gave rise to most ammonia. The optimum *p*H for deamination was 6·5.—A. T. Phillipson.

1859

OTAGAKI, K. K., BLACK, A. L., GOSS, H. and KLEIBER, M. ***In vitro* studies with rumen microorganisms using carbon-14-labeled casein, glutamic acid, leucine, and carbonate.** *J. Agric. Food Chem.*, 1955, **3**, 948–951. [Dept. Animal Husb., Univ. California, Davis.]

The action of rumen bacteria on protein and amino-acids was investigated. The bacterial fraction from sheep's rumen fluid was incubated anaerobically at 39° C. in 50-ml. amounts of suitable nutrient media, with the addition of ^{14}C-labelled casein, glutamic acid, leucine or carbonate. At the end of 48 hr. enzymic activity was terminated and the distribution of isotope in bacterial protein, volatile fatty acids and CO_2 was found. With casein, the greatest amount was accounted for in the volatile fatty acids, with little in the bacterial protein. With glutamate, a considerable proportion was found in CO_2, as well as in the volatile fatty acids, indicating amino-acid breakdown. With leucine, by contrast, little was found in CO_2, but half was recovered from fatty acids. With ^{14}C-carbonate fixation of CO_2 was demonstrated in all amino-acid components of the protein fraction.—J. C. Appleby.

1860

DAIN, J. A., NEAL, A. L. and DOUGHERTY, R. W. **The occurrence of histamine and tyramine in rumen ingesta of experimentally over-fed sheep.** *J. Animal Sci.*, 1955, **14**, 930–935. [Dept. Biochem. Nutrit., Cornell Univ., Ithaca, N.Y.]

Acute indigestion was produced in sheep overfed with 4 lb. fresh wheat or cracked maize. Samples of rumen contents were withdrawn through a rumen fistula at intervals and analysed by paper chromatography for histamine and tyramine, and the *p*H of the samples was estimated.

Value for histamine of 70 μg. per ml. were obtained in some experiments after 36 to 42 hr. At this level of histamine the animals died. At 5 μg. per ml. the animals were obviously, but not critically, ill. The severity of signs was directly related to the level of histamine. The *p*H fell as the histamine level rose. When the histamine level was high enough to be fatal the *p*H was about 4·5.—T. D. Bell.

1861

HUNGATE, R. E., FLETCHER, D. W. and DYER, I. A. **Effects of chlortetracycline feeding on bovine rumen microorganisms.** *J. Animal Sci.*, 1955, **14**, 997–1002. [Dept. Bacteriol., State Coll., Washington, Pullman.]

By a manometric technique described elsewhere (*Applied Microbiol.*, in the press), total fermentation products of the rumen contents of bullocks fed on rations with or without chlortetracycline (aureomycin) were estimated and the effect of the addition of more chlortetracycline to the fermentation apparatus was studied. The inhibition of fermentation by added antibiotic was greater in the rumen contents of animals which had not had chlortetracycline, and this showed that the rumen flora had been altered by the antibiotic in the ration.—T. D. Bell.

1862

RAVAUD, M. Recherches sur la physiologie et la pharmacodynamie des mouvements intestinaux chez les ruminants. [**Research on the physiology and pharmacodynamics of the intestinal movements of ruminants.**] *Thesis*, Toulouse, 1955, pp. 128.

The intestinal movements were studied in 28 small ruminants narcotised with chloralose, by recording pressure changes from balloons in the lumen or by simple observation of the intestines exposed in a chamber at 39° C. and high humidity. "Normal" motility was studied for 4 or 5 hr. and then the effects of different drugs.

The motility was on the whole similar to that seen in non-ruminant species, but somewhat weak. Veratrine and emetine were without effect; anticholinesterases were the most active and least dangerous stimulants of motility and atropine was the most effective inhibitor.—D. Duncan.

1863

HERNDON, J. F. and HOVE, E. L. **Surgical removal of the cecum and its effect on digestion and growth in rabbits.** *J. Nutrition*, 1955, **57**, 261–270. [Dept. Animal Husb. Nutrit., Alabama Polytech. Inst., Auburn.]

Rabbits aged 6 weeks or older were given a diet containing, per cent., extracted casein 25, maize starch 33·8, cellulose 10, vitamin mixture in sucrose 5, salts 5, cod liver oil 1, lard 19 and $KHCO_3$ 1·2, with 10 mg. α-tocopherol acetate weekly. When the rabbits were at least 8 weeks old the caecum was removed by a method which is described. The operation was successful in 5 rabbits.

After operation the rabbits lost weight for about 2 days and then resumed growth at an average

rate of about 22 g. daily, against 27 g. for normal rabbits on the same diet. They remained outwardly normal, but after periods of up to 9 months after operation enlargement of the adrenals and colon was found, and the kidneys were large, pale and slightly scarred. The rabbits excreted two types of faeces, one hard, dry and white, the other dark, irregularly shaped and moist. The faeces did not show the high protein content, the tough mucous covering or the grape-like clustering of true soft faeces, and the two types differed only in the presence of bile in the dark faeces. The rabbits did not eat their faeces.

Balance experiments with 2 normal and 2 operated rabbits in metabolism cages showed that digestibility of fat and protein were somewhat low in operated rabbits, digestibility of cellulose was normal, utilisation of Ca was normal, but losses of Na and K were 5 times normal.

It is concluded that the rabbit is not dependent on caecal micro-organisms for digestion of fibre or synthesis of vitamins, and that its digestive system is closer to that of other mammals with simple stomachs than to that of the ruminant.

1864

MYERS, K. **Coprophagy in the European rabbit (*Oryctolagus cuniculus*) in Australia.** *Austral. J. Zool.*, 1955, **3**, 336–345. [Wildlife Survey Sect. Field Stat., C.S.I.R.O., Albury, N.S.W.]

Rabbits were captured at all times of the day and night and dissected immediately. The distribution of hard and soft faecal pellets in the rectum and the presence or absence of pellets in the stomach were studied.

Soft pellets were passed and eaten underground, during the day, and hard pellets during feeding at night. The change from one type to the other commonly occurred before the rabbits moved up or down. In winter the rabbits remained above ground longer than in summer, and production of soft faeces did not last so long.

In young rabbits coprophagy began at an early age, with bodyweights of 6 oz. upwards.

It is suggested that coprophagy is most extensive and also most valuable to the rabbit during the dry summer months, when green feed is scarce.

KÜNZER, W. Untersuchungen zur Reifungszeit der Reticulocyten von Neugeborenen, jungen Säuglingen und Frühgeburten. Zugleich ein Beitrag zur Frage der Lebensdauer von Neugeborenenerythrocyten. [**Maturation time of reticulocytes of the newborn, young infants and premature infants, with a contribution on the problem of the duration of life of erythrocytes in the newborn.**] *Ztschr. Kinderheilk.*, 1955, **77**, 249–260. [Kinderklin., Univ. Würzburg.]

Samples of 3 to 5 ml. venous blood were placed in siliconed flasks with a few drops of Liquemin Roche and incubated at 37° C. Reticulocyte counts were made initially and after 2, 4, 6, 8, 10, 24 and 36 hr. in preparations stained with brilliant cresyl blue. Ten samples were of umbilical vein blood and 10 each from premature infants, infants 2 to 14 weeks old and adults.

The curves of reticulocyte counts during incubation were similar within all 4 groups. The initial values were highest in umbilical blood and declined with age. In all groups there were few or no reticulocytes to be found after 48 hr. The rate of fall of counts was steeper the higher the initial value, *i.e.*, the mean maturation time was less in infants than in adults. It is concluded that red cell formation in premature and newborn infants is at least enough to maintain the cell count in the first 3 months, and anaemia in such infants must be the result of increased breakdown.

BRING, S. V., WARNICK, K. P. and WOODS, E. **Nutritional status of school children 15 and 16 years of age in three Idaho communities; blood biochemical tests.** *J. Nutrition*, 1955, **57**, 29–45. [Dept. Home Econ. Res., Univ. Idaho, Moscow.]

Hb, packed cell volume, sedimentation rate, and, in serum, vitamin A, carotene, riboflavin, ascorbic acid, cholesterol, alkaline phosphatase, Fe and Cu were estimated in fasting venous blood samples from 280 subjects. The results of a dental and dietary survey of the children were reported previously (Absts. 1257, 5505, Vol. 25).

Significant positive correlations were found between ascorbic acid in the diet and serum ascorbic acid and between vitamin A in the diet and serum carotene. For both boys and girls significant positive correlations were found between some blood constituents, namely, vitamin A and carotene, free and total riboflavin, free and total cholesterol, Hb and packed cell volume, carotene and ascorbic acid, vitamin A and both free and total cholesterol, Cu and sedimentation rate.

Some other constituents were significantly correlated in blood of boys only. Mean values for girls were significantly higher than for boys for sedimentation rate, ascorbic acid, free cholesterol and Cu. Boys had significantly higher mean values than girls for alkaline phosphatase, Hb and packed cell volume. The only age difference was in alkaline phosphatase, which was significantly higher at 15 than at 16 years.—F. C. Aitken.

1867

SCHULTZE, A. B. **Changes of certain characters of the blood of dairy calves during one year of life and their possible relation to rate of gain in body weight.** *Growth*, 1955, **19,** 141–149. [Dept. Dairy Husb., Univ. Nebraska.]

Red cell count, sulphydryl content, sugar, Hg, haematocrit and eosinophil count were estimated in the blood of 29 Holstein calves at intervals of 30 days or less during the first year of life. There were significant differences between calves of the same age in red cell count, sulphydryl content, Hb and haematocrit. Significant changes occurred with advancing age in all the values studied. That most closely related to rate of weight gain was the haematocrit. A significant correlation was found between sulphydryl content and haematocrit at 90 to 125 days and the rate of gain of the calf from 100 to 360 days of age. Most of the calves were born in winter or spring, and only 7 in summer. The influence of season and the time of birth on the changes is discussed.—T. D. Bell.

1868

HOLMAN, H. H. **The blood picture of the cow.** *Brit. Vet. J.*, 1955, **111,** 440–457. [Agric. Res. Counc., Field Stat., Compton, Berks.]

Blood samples of 81 Ayrshire cows over 3 years old were examined. From the results, and those of other workers, values of: Hb 11 g. per 100 ml., packed cell volume 35 per cent., M.C.H.C. 33 per cent., red cells 6 million per c. mm., sp. gr. 1·052, percentage distribution of leucocytes, neutrophils 30, lymphocytes 52, monocytes 7 and eosinophils 11, are suggested as good working averages for European cattle in temperate zones.

From the estimated correlations between red cell measurements it is shown that a better indication of anaemia is obtained from packed cell volume or sp. gr. than from red cell count.

Causes of variations in the blood picture are discussed, and values of cell measurements which could be considered pathological are suggested.

T. D. Bell.

1869

EFTIMOV, B., PETROV, K. and KONSTANTINOV, G. Vliyanie na lyatnoto lagerno-pasishchno otglezhdane vorhu doini kravi. [**Effect of summer pasture-camps on dairy cows.**] *Nauch. Trudove, Selskostop. Akad. "Georgi Dimitrov," Sofia*, 1953–54, **4/5,** 261–269. Russian summary.

In cows after 3 months at summer pasture the pulse rate was 10 per cent. higher, respiration rate 32·5, red cell count 9·8, leucocyte count 24·9, Hb 4·04, Ca 11·5, and alkali reserve 7·8 per cent. higher than during the stall-feeding period. Cows at pasture from July to October gave 11·8 per cent. more milk than they gave indoors in the same period of the previous year.

A period at pasture is considered to be good for the health and productivity of cows under Bulgarian conditions. (From summary.)

1871

ROSSI-FANELLI, A., CAVALLINI, D., DE MARCO, C. and TRASATTI, F. Emoglobina fetale. 1. Analisi quantitative degli aminoacidi della emoglobina umana fetale cristallizzata ed alcuni accorgimenti tecnici. [**Foetal haemoglobin. 1. Quantitative estimation of the amino-acids in crystalline human foetal haemoglobin, and some hints on technique.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 328–330. [Ist. Chim. Biol., Univ. Rome.]

Sixteen amino-acids were estimated by paper chromatography in crystalline foetal human Hb after hydrolysis for 24, 48 or 72 hr. with 6*N* HCl. The values are tabulated; they did not vary much with progress of hydrolysis, except those for lysine and serine, which decreased. Comparative values are tabulated for the amino-acids in adult and foetal term Hb and in that of an 8-month foetus.

1872

HUISMAN, T. H. J., JONXIS, J. H. P. and DOZY, A. **Is foetal haemoglobin present in the blood of normal human adults?** *Biochem. biophys. Acta*, 1955, **18,** 576–577. [Dept. Paediat., Univ. Groningen.]

Small amounts, 0·3 to 0·4 per cent., of alkali-resistant Hb were shown to be present in blood samples from the 3 authors. The amino-acid

composition of this fraction was similar to that of foetal Hb.—G. F. Garton.

1873

SMITH, S. G. (with LASATER, T. E.) **Normal hemoglobin formation in the dog.** *Amer. J. Physiol.*, 1955, **182,** 433–438. [Dept. Bacteriol., Sch. Med., Duke Univ., Durham, N.C.]

The blood picture was studied every month or two from weaning at 7 weeks until 65 weeks in 6 healthy mongrel dogs and from weaning until $10\frac{1}{2}$ years in one dog, all of which were given a diet of casein 40, sucrose 34, cottonseed oil 10, cod liver oil 2, salt mixture 4 and dried brewer's yeast 10 per cent., with added vitamins of the B group. Food intake was recorded daily and bodyweight twice weekly.

The normal Hb value of the mature dog is 18 g. or more per 100 ml. blood. In the 6 dogs the mean values from reaching maturity at 30 weeks until the end of the experiment were: red cell count $7{\cdot}39 \pm 0{\cdot}088$ million per c. mm., Hb $18{\cdot}5 \pm 0{\cdot}139$ g. per 100 ml. and haematocrit $55 \pm 1{\cdot}65$ per cent. The dog studied for $10\frac{1}{2}$ years maintained comparable values from maturity at 37 weeks except when it was ill.—G. F. Garton.

1874

CRUMP, E. P., SCHECK, J. F., MUKHERJI, B. K., HARRIS, R. and TURNER, W. D. **Oxygen therapy in the newborn premature infant. 1. Its relation to some aspects of protein metabolism.** *J. Pediat.*, 1955, **47,** 442–449. [Meharry Med. Coll., Nashville, Tenn.]

Infants breathing unfortified incubator air were compared with similar infants for whom the incubator air was fortified with oxygen, usually 24 to 34 per cent. but sometimes 38 to 42 per cent.

Infants exposed to extra oxygen lost more weight on the average than did the controls. During the first week of life extra oxygen did not affect plasma protein values, but at 7 to 14 days values were lower for control than treated infants. Blood N.P.N. was consistently higher in treated infants than in controls. A similar pattern was found for blood urea N. Both N.P.N. and blood urea N values rose during the 2 weeks of study. Blood uric acid fell sharply between the fifth and seventh days and the fall was greater in infants not receiving oxygen.—F. C. Aitken.

1875

CLOSE, J. Le taux des protéines sériques chez le nourrisson africain. [**Concentration of serum proteins in African infants.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35,** 129–144. [Inst. Recherche Sci. Afrique Centrale, Centre Recherche Sci. Kivu, Lwiro, Belgian Congo.] Flemish summary.

Total protein and protein fractions were estimated by electrophoresis in the serum from 141 apparently healthy country infants up to 24 months old. The values were grouped by periods of 2 months. Mean total protein in g. per 100 ml. was at birth $5{\cdot}35 \pm 0{\cdot}092$; it decreased to $4{\cdot}94 \pm 0{\cdot}094$ in the first 2 months and then increased steadily to the 18th month, when it dropped slightly, to increase again to $6{\cdot}62 \pm 0{\cdot}261$ in the period from $22\frac{1}{2}$ to $24\frac{1}{2}$ months. Serum albumin, which was $3{\cdot}66 \pm 0{\cdot}104$ g. per 100 ml. at birth and $3{\cdot}75 \pm 0{\cdot}116$ at 24 months, also showed a slight fall immediately after birth and during the 18th to 22nd months. The α- and β-globulins rose immediately after birth and subsequently varied only slightly, but γ-globulin fell from $1{\cdot}11 \pm 0{\cdot}084$ g. per 100 ml. at birth to $0{\cdot}44 \pm 0{\cdot}054$ during the first 2 months, and then showed a steady rise to $1{\cdot}43 \pm 0{\cdot}139$ at the age of $16\frac{1}{2}$ to $17\frac{1}{2}$ months, after which it dropped to $1{\cdot}15 \pm 0{\cdot}116$ between $20\frac{1}{2}$ and $22\frac{1}{2}$ months and then rose again to $1{\cdot}64 \pm 0{\cdot}211$ in the next 2 months. With increasing age the dispersal about the mean increased. This is thought to be explained by the different foods given after weaning, infestation with parasites and infection.

In the American infant the albumin value rises steadily during the first 10 months, but in the African infant it does not rise appreciably above the birth value during the first 2 years. It is suggested that the failure to synthesise albumin results from protein deficiency caused by the African woman's insufficient secretion of milk, which is especially marked about the 5th month, at which time the rate of weight increase slackens and the albumin value ceases to rise. The initial albumin level found was the same as that of 4 newborn European infants in Katana. The α- and β-globulin values resembled those of the European infants. γ-Globulin at birth was lower than the mean for the 4 European infants; there was a similar fall after birth in both groups, but the rise in the value for Africans was greater than in the European infants. The findings are related to the critical period at weaning experienced by African infants. The changes in the albumin value can be related to protein deficiency in the diet, but the cause of the variations in globulin is less definite; deficient diet may play a part, but racial characteristics and liver insufficiency must be considered.—L. Wills.

1876

ORLANDINI T., O., SASS-KORTSAK, A. and EBBS, J. H. **Serum gamma globulin levels in normal infants.** *Pediatrics*, 1955, **16,** 575–584. [Dept. Paediat., Univ. Toronto.] Spanish and Interlingua summaries.

Proteins were measured in samples of blood serum from 28 mothers within 20 hr. before delivery, in the cord blood of their infants immediately after delivery and, for comparison, in samples from 13 adult women. Mean values in mg. per 100 ml. for the subjects in that order were : γ-globulin 0·82, 0·90 and 0·96, total globulin 3·19, 2·61 and 3·31, albumin 3·50, 3·63 and 4·44 and total protein 6·68, 6·24 and 7·75. The difference for γ-globulin between mothers and infants was significant only at the 5 per cent. level. Total globulin in infants was significantly lower than in mothers.

The changes with ageing were studied in 122 [112 in Table 2, p. 579] other children aged from 1 week to 24 months. In the first month there was a fall in γ-globulin which was most rapid in the first week. The level remained low until 3 months, mean for 7 infants 0·32 g., and thereafter rose steadily, mean for 14 children from 18 to 24 months 0·77 g. Data collected over the first week for 18 infants, of whom 13 were breast fed and 5 artificially fed, indicated no effect of γ-globulin in colostrum on the level in the infants' blood. Since total globulin in serum did not change during the first week of life, the tentative conclusion is that the amounts of α- and β-globulins may have risen. These findings are discussed with those of other workers on antibody production, and the hypothesis that practically no γ-globulin is formed in the first month of life seems warrantable.

D. Harvey.

1877

GEUBELLE, F. and NEVEN, M. Étude du taux de gamma-globulines chez le prématuré. 1. Taux pendant la première semaine de la vie. [**Concentration of gamma globulin in the premature infant. 1. Concentration to the first week of life.**] 2. Évolution du taux de la première à la cinquième semaine. [**2. Course of the concentration from the first to the fifth week.**] *Acta paediat. belg.*, 1955, **9,** 145–151. [Clin. Policlin. Maladies de l'Enfance, Univ. Liège.]

1. In 22 premature infants weighing from 1000 to 2500 g. at birth serum γ-globulin during the first week of life ranged from 0·20 to 1·25 g. per cent. ; in general γ-globulin varied directly with birthweight, but there was no relation between γ-globulin and degree of prematurity.

2. In most of the 12 infants examined again during the fifth week of life γ-globulin had fallen by from 40 to 65 per cent. of the initial value.

SMITHIES, O. **Zone electrophoresis in starch gels: group variations in the serum proteins of normal human adults.** *Biochem. J.*, 1955, **61,** 629–641. [Connaught Med. Res. Labs., Univ. Toronto.]

Protein was separated by zone electrophoresis in a starch gel made up in buffer and detected by staining. As little as 0·02 ml. serum could be used. Serum samples from over 40 normal adults were divided into 3 groups on the basis of the presence of several previously undescribed non-dialysable components. These were able to bind Hb and they migrated in the α_2-globulin position during filter paper electrophoresis.—A. Hepburn.

SATOSKAR, R. S. and LEWIS, R. A. **The effect of antibiotic dietary supplements upon the plasma proteins of Indian students.** *Indian J. Med. Res.*, 1955, **43,** 415–422. [Dept. Pharmacol., Seth G.S. Med. Coll., Parel, Bombay 12.]

Groups of students were given by mouth 50 mg. terramycin, 50 mg. tetracycline, 100 mg. erythromycin or a placebo for 2 months and blood albumin and globulin were estimated before, during and after treatment. Tetracycline and terramycin both produced a rise in albumin and a fall in globulin. Erythromycin had no effect except in one student showing a sprue-like syndrome. Improvement in his condition was noted as well as a rise in albumin and a fall in globulin. The results confirm the beneficial effect of antibiotics in human diets deficient in protein.—J. S. Thomson.

RICE, C. E. and DUHAMEL, L. **The effect of prolonged injection of ethionine on rabbits and guinea pigs fed a high cholesterol diet. 4. On serum proteins in rabbits.** *Canadian J. Comp. Med.*, 1955, **19,** 299–304. [Div. Animal Pathol., Animal Dis. Res. Inst., Canada Dept. Agric., Hull, Que.]

Two groups of 6 rabbits were injected 5 times weekly with 25, 50 or 100 mg. ethionine ; 2 similar groups were left untreated. One treated and one

untreated group were given a stock pellet diet, the other 2 groups the same diet supplemented with cholesterol in cottonseed oil. One rabbit from each group was bled after from 7 weeks to 6 months and killed immediately; the serum was analysed for total protein, globulin and albumin.

The total protein and globulin of the serum of rabbits given the high-cholesterol diet were higher than in rabbits on stock diet; the mean albumin : globulin ratios were 0·99 and 1·36, respectively. In the ethionine-treated group on the stock diet total serum protein fell below the level for the controls, but in the treated group on the high-cholesterol diet the level was maintained. In sera of both these groups an increase in globulin and a decrease in albumin occurred after 7 weeks or 3 months of treatment with ethionine, but after 4 to 6 months' treatment the values for both were normal.—G. F. Garton.

VANSTONE, W. E., MAW, W. A. and COMMON, R. H. **Levels and partition of the fowl's serum proteins in relation to age and egg production.** *Canad. J. Biochem. Physiol.*, 1955, **33,** 891–903. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

In poultry, total serum protein, estimated by the biuret reaction (see Abst. 4055, Vol. 24) and fractions, by zone electrophoresis on paper (methods described), were studied from the 14th day of incubation to the 13th week of laying. The eggs were from New Hampshire hens mated with a cock of the Barred Plymouth Rock breed. The birds were fed on a commercial chick starter and then on broiler pellets, finally supplemented with grain and oyster shell; from 4 weeks they were caged individually. The results are given in tables and diagrams.

Total serum protein amounted to 0·9 g. per 100 ml. in the 14-day embryo and rose to 2·1 g. at hatching and then more gradually. For the first 5 weeks there was no sex difference. Most of the subsequent analyses were for pullet chicks, in which there was a slow rise to about 4 g. per 100 ml. and then a more rapid rise to 5·4 g. just before the first egg was laid, followed by a rapid fall and later a return to the pre-laying value of 4 g. per 100 ml. The peak is ascribed to oestrogen activity.

Albumin and α_2- and β-globulin were present in embryo blood. At hatching α_1- and γ-globulin had appeared and by 7 days α_3-globulin. A week or two before laying began, 2 other fractions appeared, as reported earlier (Abst. 4055, Vol. 24). These largely accounted for the rise in total serum protein. Similar fractions were previously found in egg yolk (Abst. 3199, Vol. 24). They are thought to be phosphoproteins.—W. M. Deans.

1885

SOHAR, E., BOSSAK, E. T. and ADLERSBERG, D. **Species differences in serum glycoproteins of man, dog and rabbit, by paper electrophoresis.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 305–308. [Dept. Med., Mount Sinai Hosp., New York.]

MACDONALD, M. A. and WHITE, R. R. **Levels of non-protein and amino-acid nitrogen in blood of pasture-grazing beef calves.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37,** 259–266. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton.]

Blood samples were taken weekly from 3 heifer and 3 bull, and monthly from 2 heifer and 7 bull Aberdeen-Angus weaned calves during a grazing season of 12 weeks. N.P.N. and amino-acid N were estimated. The average N.P.N. content was 41·0 mg. per 100 ml., range 30·2 to 50·1, and that of amino-acid N 9·33 mg. per 100 ml., range 7·7 to 11·2. There was no pattern in the wide variations found in individual calves, and there was also wide variation between calves. In the literature, which is briefly reviewed, growth hormones have been reported to show a homeostatic effect on blood constituents, but this was not apparent in the present trial. Reasons for this are discussed.—T. D. Bell.

1887

KIDWELL, J. F., WADE, M. A. and HUNTER, J. E. **The relation of blood glutathione level to growth and body size in beef cattle.** *Growth*, 1955, **19,** 177–185. [Dept. Animal Husb., Univ. Nevada, Reno.]

Blood glutathione, Hb, total cell count, heart girth and bodyweight of 47 Hereford bullocks aged from 15 to 21 months were estimated at the beginning and end of an 84-day feeding period. Efficiency of feed conversion was calculated.

No relation was found between blood glutathione and liveweight or rate of gain, but there was a small correlation between glutathione and feed efficiency and heart girth. Glutathione was related to Hb and cell count. The level of glutathione was significantly higher at the end of the feeding period. The correlation between these values was smaller than that found by other workers, and this was thought to emphasise the importance of the plane of nutrition. The data

indicate that blood glutathione would not be of real value in selection of beef cattle for rate of gain and efficiency. On the other hand, the small correlations found suggest that there may be some metabolite which would be suitable.—T. D. Bell.

1888

HAVEL, R. J., EDER, H. A. and BRAGDON, J. H. **The distribution of chemical composition of ultracentrifugally separated lipoproteins in human serum.** *J. Clin. Invest.*, 1955, **34,** 1345–1353. [Lab. Metabol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Lipoproteins were separated from serum by repeated ultracentrifuging after the solvent density had been increased progressively by the addition of a solution of NaCl and KBr. The main fractions separated at densities below 1·019, 1·019 to 1·063 and above 1·063 were analysed for total cholesterol, lipoid P and protein. In young adults about two-thirds of the cholesterol and half the lipoid P were in the middle fraction. In disorders with high serum lipoproteins, one or both of the 2 lower density fractions were affected. The fraction of highest density was sometimes affected. Serum from rabbit, rat, pig, hamster, dog and monkey had wider variations in distribution and composition of lipoproteins than that of man. More lipid was associated with the fraction of highest density than in man.—A. Hepburn.

1889

MANN, G. V., NICOL, B. M. and STARE, F. J. **The beta-lipoprotein and cholesterol concentrations in sera of Nigerians.** *Brit. Med. J.*, 1955, ii. 1008–1010. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Blood samples from 46 African men living in 3 different areas of Nigeria were analysed in Boston, U.S. Though their dietary habits differed there was little difference in the content of total cholesterol and β-lipoproteins in their sera. For all subjects the mean values were for total cholesterol $122{\cdot}5 \pm 40{\cdot}6$ and for lipoproteins S_f 12–20, $24{\cdot}1 \pm 12{\cdot}5$ and S_f 20–100, $40{\cdot}6 \pm 28{\cdot}5$ mg. per 100 ml. For 30 of these men a group of American (U.S.) men comparable for age and weight were chosen. The difference in total cholesterol content of their blood, 83 mg. per 100 ml. greater in the Americans, was highly significant; that in S_f 12–20 β-lipoproteins, 9 mg. per 100 ml. greater in the Americans, was also significant, but the difference for S_f 20–100 lipoproteins was not so. Diet studies (see Absts. 5374, Vol. 19 and 2795, Vol. 22 and Title 3397, Vol. 23) indicated energy intake low in relation to activity, and low intake of fat. Clinical work in Nigeria and post-mortem studies in the Gold Coast, where conditions are similar (Edington, *Trans. Roy. Soc. Trop. Med.*, 1954, **48,** 419), showed that atherosclerosis and its complications are rare.

The findings are discussed in opposition to the view of Keys (see especially Abst. 5096, Vol. 24) that such differences result from differences in intake of fat. The low level of lipids in these Africans is thought to support the hypothesis, already advanced from work on Guatemalans (Mann *et al.*, in the press), that a high rate of muscular activity is the controlling agent.

WILGRAM, G. F., LEWIS, L. A. and BLUMENSTEIN, J. **Lipoproteins in choline deficiency.** *Circulation Res.*, 1955, **3,** 549–552. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Fifty-five male rats were given a high-fat, choline-deficient diet; 35 were used as controls, with a choline supplement; 10 males were given a synthetic low-fat, high-protein, choline-supplemented diet and 10 females were used as choline-deficient controls to be compared with the choline-deficient males. After 4 weeks the rats were killed and the serum lipoproteins were studied by ultracentrifugal analysis.

All the choline-deficient animals showed small amounts of the low-density lipoprotein fractions; the α-lipoproteins of the - S 1–10 and - S 10–15 classes were low in choline-deficient males. The significance of the findings in connection with the production of cardiovascular disease by choline deficiency is discussed.—G. F. Garton.

1891

MOORE, N. S., FRYER, J. H., YOUNG, C. M. and MAYNARD, L. A. **Blood lipid levels as influenced by weight reduction in men.** *Amer. J. Clin. Nutrit.*, 1955, **3,** 397–402. [Sch. Nutrit., Cornell Univ., Ithaca, N.Y.]

A study of total lipids, phospholipins and cholesterol in the serum of 24 men undergoing weight reduction revealed wide fluctuations. Some regression coefficients of lipids on weight were significant, but the changes in lipid levels did not appear to be of physiological importance.

SAARINEN, P. **Diet and plasma cholesterol in dairy cows.** *Maataloust. Aikakausk.*, 1955, **27,** 117–141. [Dept. Animal Husb., Univ. Helsinki.] Finnish summary.

Plasma cholesterol was estimated in the blood of 141 Ayrshire cows in 12 trials. Statistical analysis of the results showed no correlation between cholesterol value and age. In the first 9 trials the cows were in normal condition; in the last 3 they were fat, and cholesterol values were higher. A positive effect on cholesterol values of the proportion of fat in the ration, the energy

requirement of the cow and the digestible crude fibre in the ration was found. Digestible crude protein showed a positive correlation with cholesterol value in the normal cows, but in the fat cows and in sterile cows the correlation was negative. Temporary changes in the intake of energy did not affect plasma cholesterol.—T. D. Bell.

WYSOCKI, A. P., PORTMAN, O. W. and MANN, G. V. **Bile acids in blood: methods and their application to studies of experimental atherosclerosis in monkeys.** *Arch. Biochem. Biophys.*, 1955, **59,** 213–223. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The bile acids were segregated from serum and estimated spectrophotometrically under conditions which are described; the acids separately estimated were cholic, deoxycholic and chenodeoxycholic, and recoveries of 95 to 98 per cent. were obtained.

In 6 human subjects with high serum cholesterol, mean 388 mg. per cent., and 7 normal subjects with mean serum cholesterol 234 mg. per cent., the chenodeoxycholic acid values were 13·0 and 6·5 mg. per cent., respectively, but there was no significant difference in cholic or deoxycholic acid.

High levels of serum cholesterol and α-lipoprotein were produced in monkeys given for a year diets containing 20 per cent. soya bean α-protein with or without 1 per cent. cholic acid, or 25 per cent. casein with 1 per cent. cholic acid. Such monkeys had normal cholic and deoxycholic acid levels in the serum, but high chenodeoxycholic acid. All the monkeys with high serum cholesterol, whether it was produced by diets with α-protein or with casein and cholic acid, had aortic atherosclerosis.—D. Duncan.

1895

HALLMAN, N. and SALMI, I. **Citric acid in maternal and cord blood.** *Ann. Paediat. Fenn.*, 1955, **1,** 333–337. [Child. Clin., Univ. Helsinki.]

Citric acid, total protein, Ca and inorganic P were estimated in venous blood of women either immediately before or from 10 to 55 min. after delivery and in samples from the umbilical vein and artery. The data for 12 mothers gave mean values of 6·1, 5·2 and 4·6 mg. citric acid per 100 ml. plasma in that order, which were above the range 1·7 to 4·0 mg. taken to be normal. There was no correlation between the amount of citric acid and of the other constituents studied. Signs of tetany were not seen.—D. Harvey.

1896

BALLABRIGA, A. Sobre los electrolitos en el recien nacido. [**Electrolytes in the newborn infant.**] *Rev. española Pediat.*, 1955, **11,** 309–315. [Centro Estud. Crecimiento Nutric. Infant., Barcelona.] French, English and German summaries.

The subjects were 20 normal term infants from normal births, except 1 born by caesarean section, all in the University Obstetrical Clinic of Barcelona. Blood samples were taken in the first 24 hr. and 4 times more in the first 9 days of life. Samples were taken also from the mothers.

The mean serum K was 5·1 m. equiv. per litre in the mothers and 5·4 in the infants; plasma Na values, also in m. equiv. per litre, were 123·4 to 148·1, mean 136 for mothers, 128·4 to 153, mean 140·4 for infants in the first 24 hr., and 128·2 to 158, mean 138·1 for infants up to 9 days old. Equivalent values for plasma Cl were 95·1 to 110, 102·5; 97·6 to 113, 103·5; and 99·2 to 122, 107·7. Alkali reserve had a mean value of 23·02 m. equiv. per litre in the mothers and 20·3 in the newborn infants; the value for any infant was lower than that of the mother. Adult values were reached in 7 to 9 days. Inorganic P values were 1·8 to 3·4, mean 2·3 m. equiv. per litre in the mothers, 2·8 to 3, mean 3·2 [figures as printed] in infants in the first 12 hr. and 2·6 to 3·7, mean 3·3, in infants 7 to 9 days old. Plasma protein values of the mothers, who although apparently healthy were of poor social class and may have had a low protein intake, had a mean of 14·6 m. equiv. per litre; those of the infants were 13·3 at birth and 13·6 after 7 to 9 days.

The values are compared with others in the literature.—D. Duncan.

1897

VAN ZYL, A. and KERRICH, J. E. **Protein-bound iodine in the serum of the baboon (*Papio ursinus*).** *S. African J. Med. Sci.*, 1955, **20,** 9–22. [Dept. Physiol., Univ. Witwatersrand.]

An experimental colony of captive baboons housed in open-air cages and fed on a standard ration was kept under observation during the years 1952–54. The protein-bound iodine (PBI) content of the serum of 77 of these animals, ranging in age from 2 weeks to 15 years, was estimated in a total of 516 analyses.

The average serum PBI of the adult baboon was 3·99 ± 0·27 μg. per 100 ml. The average PBI of 6 human subjects in the climatic conditions of Johannesburg, 6000 ft. above sea level, was 5·70 ± 0·67. The PBI of monkeys was 3·59 ± 0·81, oxen 3·61 ± 0·44, rats 2·36 ± 0·91, fowls 1·03 ± 0·26 and *Xenopus laevis* 5·17 ± 0·94 μg. per 100 ml. The average serum PBI of the baboons fell from about 6·5 μg. per 100 ml. in infancy to

about 4·0 at 5 years and over. This gradual decrease with age conformed with that in man.

1898

AGARWAL, S. C. and MISRA, S. S. **Observations on the level of unsaturated iron-binding capacity, total iron-binding capacity and saturation percentage in pathologic subjects.** *Indian J. Med. Res.*, 1955, **43**, 403–409. [Dept. Med., K.G. Med. Coll., Lucknow.]

Serum Fe and unsaturated Fe-binding capacity were estimated and the degree of saturation was calculated by expressing the first as a percentage of the sum of the two. The 87 subjects were mainly patients admitted to hospital; 27 had Fe deficiency anaemia, 28 infections, 1 acute hepatitis and 13 cirrhosis of the liver, 5 nephritis, 5 leucaemia and 8 malignant disease. The individual values are tabulated.

In anaemia serum Fe and saturation were low. In infections other than acute hepatitis and kala azar each of the values was low; in the 2 exceptional conditions serum Fe was high and unsaturated Fe-binding capacity low. Values were low for Fe-binding capacity in cirrhosis and for serum Fe in malignant disease; they were variable in leucaemia, serum Fe usually being high.

TISSUES

1903

GOPALAN, C., SRIKANTIA, S. G. and VENKATACHALAM, P. S. **Body composition and basal metabolism of normal subjects.** *J. Appl. Physiol.*, 1955, **8**, 142–144. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

The body composition of 9 normal Indian subjects was ascertained by the method of McCance and Widdowson (Abst. 1425, Vol. 21), and their body fat was estimated also from sp. gr. measurements. Basal metabolic rates were estimated on the same day as body composition, with a Benedict Roth apparatus.

The values for total body water, water in fat-free mass, thiocyanate space and bone minerals agreed well with those reported in the literature. Body fat estimations by the 2 methods agreed closely.

The possibility of using cell solids as a reference for B.M.R. measurements is suggested.

INGLIS, J. S. S., JENNINGS, F. W., LAUDER, I. M., MULLIGAN, W. and WEIPERS, M. **The volume distribution of intravenously injected ^{24}Na in bovines.** *Vet. Rec.*, 1955, **67**, 765–768. [Vet. Sch., Univ. Glasgow.]

A catheter was inserted into the jugular vein to facilitate serial blood sampling in cattle. Each animal received an injection of ^{24}Na containing from 30 to 300 μC. of activity, and blood samples were taken at 30-min. intervals from $2\frac{1}{2}$ to 6 hr. later. "Radio-sodium space" was calculated as an indication of extracellular fluid volume.

The ^{24}Na space ranged from 10·8 litres in a young calf to 152·0 litres in an adult cow. The ratio of extracellular space to bodyweight was highest in calves and decreased with growth. Repeat estimations on 3 steers at grass, 4 on each animal at weekly intervals, showed fair agreement.

A syringe holder to protect the operator from the relatively large doses of radio-active material needed for large animals is described.

D. Duncan.

1905

WIDDOWSON, E. M. and MCCANCE, R. A. **Physiological undernutrition in the newborn guinea-pig.** *Brit. J. Nutrition*, 1955, **9**, 316–321. [Med. Res. Counc. Dept. Exp. Med., Univ. Cambridge.]

Ten litters of guineapigs, 23 animals, were killed at birth and 7 litters, 16 animals, were killed when they were 1 week old. The mothers had been reared on a stock diet of sugar-beet pulp, bran, oats and greens and the 16 young not killed at birth were allowed free access to the same diet.

The livers were analysed apart from the remainder of the body ; serum samples were taken for estimation of chloride.

The average chemical composition of the bodies of the week-old guineapigs showed an increase in the percentage of water, a decrease in the percentage of fat and a decrease in the N : K ratio as compared with the composition of the bodies of guineapigs killed at birth. In the livers of the week-old animals there was a large loss of weight, a decrease in the size of the individual liver cells and an increase in their number, an increase in protein content, a decrease in the percentages of glycogen and fat, an increase, but not in proportion to the increase in protein, in the percentage of K, a decrease in the percentage of Na and an increase in the N : K ratio.—G. F. Garton.

1906

BABINEAU, L. M. and PAGÉ, E. **On body fat and body water in rats.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 970–979. [Dept. Physiol. Nutrit., Laval Univ., Quebec.]

Four groups of 30 adult male rats had initially the same average bodyweight. One group was killed at the beginning of the experiment, the others after 20 to 21 days at room temperature or 30 to 31 or 56 to 57 days at 11° C. The diet contained, per cent., casein 20, Crisco 8, wheat germ oil 2, salts 5, cellulose 2 and sucrose 63, with vitamins. The carcases of all the rats were analysed.

The rats killed after a month in the cold had gained, compared with those killed initially, a mean of 9·4 g. non-fat dry matter and lost an identical amount of fat. The net gain of 16 g. in carcase weight was due to water. The controls killed after 3 weeks at room temperature had gained an identical amount of non-fat dry matter, but had also gained fat and water and their carcases were 20 g. heavier than those of rats exposed to cold. Rats exposed to cold for a second month gained twice as much bodyweight as in the first month, but only one-seventh of the amount of non-fat dry matter. Liveweight is thus an unreliable index of active growth.

Water in all groups comprised from 71·05 to 71·79 per cent. of fat-free bodyweight and none of the regression coefficients differed significantly from the rest. The influence of fat was negligible. The total body water could be used to predict non-fat dry matter with a high degree of accuracy. In samples of adipose tissue the ratio of water to fat-free dry matter was similar to that in the whole body.—D. Duncan.

1907

BRAUDE, R., COATES, M. E., DAVIES, M. K., HARRISON, G. F. and MITCHELL, K. G. **The effect of aureomycin on the gut of the pig.** *Brit. J. Nutrition*, 1955, **9**, 363–368. [Nat. Inst. Res. Dairying, Univ. Reading.]

Three experiments are reported, with 52 pigs fed on a practical ration from weaning to pork or bacon weight, half of which received Aurofac 2A at the rate of 20 g. per ton. At slaughter measurement was made of gut length and weight ; in one experiment liver, kidney and spleen were weighed and the gut was analysed for dry matter, crude fat and total nitrogen. Organ measurements were adjusted to a constant bodyweight.

Gut weight tended to be reduced in the group receiving aureomycin, but gut length was not affected, which indicated a thinning of the gut in the treated groups. There was no effect on weight of liver, kidney or spleen, and no chemical or histological change in the intestine.

J. S. Thomson.

1908

WOLF, R. C. and LEATHEM, J. H. **Hormonal and nutritional influences on the biochemical composition of the rat testis.** *Endocrinology*, 1955, **57**, 286–290. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

Immature male rats weighing 60 to 65 g. had their adrenals removed and were maintained with cortisone. They and unoperated rats received one of the following diets : Purina fox chow ; a 20 per cent. protein diet containing casein, groundnut flour or wheat gluten ; a 5 per cent. casein diet made isocaloric with the others by extra carbohydrate. After 20 days the rats were killed and their testes were examined. The testes were heaviest after fox chow or 20 per cent. casein diets. The dry testes contained initially 72·7 per cent. protein, and this was maintained on 20 per cent. casein diet, but fell when the diet contained 5 per cent. casein or 20 per cent. wheat gluten or groundnut protein, and was less in adrenalectomised than in normal rats. The lipid content was not significantly affected by diet or adrenal removal, nor was glycogen, except that it was low on the low-casein diet.—D. Duncan.

1909

SHETLAR, M. R. and MASTERS, Y. F. **Effect of age on polysaccharide composition of cartilage.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 31–33. [Res. Lab., Veterans Admin. Hosp., Oklahoma City.]

Costal cartilage was obtained from patients who had died from different disorders, at ages from the foetus to 88 years.

The uronic acid content fell progressively from mean values of 7·8 per cent. of the dry matter in 5 foetuses to 1·3 in 4 subjects from 71 to 88 years old, giving calculated chondroitin sulphate contents of from 19·1 to 3·2 per cent. Hexosamine also declined with age, but much less strikingly, from

8·2 to 5·4 per cent. If the excess of hexosamine over that calculated to be in the chondroitin sulphate is assumed to be contained in neutral polysaccharides, the latter increased with age until maturity and were then constant.—D. Duncan.

1910

IVANOV, I. I. and BLOKHINA, V. D. Fraktzionnyi sostav belkov gladkoi muskulatury pozvonochnykh zhivotnykh. [**Fractional composition of the proteins of vertebrate smooth muscle.**] *Biokhimiya*, 1955, **20**, 292. [Moscow.]

Electrophoretic fractionation of the proteins of smooth (stomach) and striated muscle of pigeons, rabbits and dogs showed that actomyosin was not the substrate involved in maintaining smooth muscle tone.—D. W. Taylor.

A new protein has been extracted from rabbit and lamb foetal muscle which has extraction and solubility properties similar to those of myosin, but differs from it in electrophoretic mobility. It has been given the name metamyosin.

J. S. Thomson.

1912

ROTHSCHILD, M. A., BAUMAN, A., YALOW, R. S. and BERSON, S. A. **Tissue distribution of I^{131} labeled human serum albumin following intravenous administration.** *J. Clin. Invest.*, 1955, **34**, 1354–1358. [Radioisotope Serv., Veterans Admin. Hosp., Bronx, N.Y.]

Two patients with severe heart disease were given intravenous injections of 112 and 107 μC. of human serum albumin labelled with ^{131}I. Ten drops of Lugol's solution daily inhibited the uptake of free I by the thyroid. Serial blood samples were taken and urine was collected. Plasma concentrations of labelled albumin were estimated up to the time of death, and at post-mortem examination tissues were obtained for estimations of radioactivity.

Plasma along with the extravascular spaces of skin, muscle and the large thoracic and abdominal viscera accounted for 75 to 80 per cent. of the total exchangeable albumin in the body. There was a high albumin concentration in whole skin. The extravascular space of the liver contained less than 1 per cent. of the total exchangeable albumin. Complete equilibration of albumin in viscera, skin and muscle with albumin in plasma required 4 to 5 days.—B. W. Simpson.

1913

WINNICK, T., WINNICK, R. E., ACHER, R. and FROMAGEOT, C. **Amino acids and peptides of posterior pituitary and hypothalamus tissues.** *Biochim. biophys. Acta*, 1955, **18**, 488–494. [Lab. Chim. Biol., Fac. Sci., Paris.] French and German summaries.

Bovine and pig tissues were used; the methods of preparation of the extracts are described.

In bovine posterior pituitary tissue the concentration of peptides was about 4 times that commonly attributed to known peptide hormones; the value for pig was almost twice that for bovine posterior pituitary tissue. Identification of the amino-acids in a peptide fraction adsorbed on charcoal suggested the existence of substances other than the hormones vasopressin, intermedin and oxytocin. Bovine anterior pituitary differed from posterior pituitary tissue in having no significant peptide pool. Like brain tissue, it was rich in glutamine and glutamic acid.—D. Harvey.

BOUCEK, R. J., NOBLE, N. L. and KAO, K. Y. T. **The conjugated lipids of connective tissue of the rat and rabbit.** *Circulation Res.*, 1955, **3**, 519–524. [Res. Lab., Miami Heart Inst., Fla.]

1916

HAWKE, J. C. **Volatile fatty acids in phospholipids.** *Nature*, 1955, **176**, 882. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Lipids were extracted with ethanol and ether from bovine muscle which had been freed of visible fat. The lipids were separated into glycerides and crude phospholipins by acetone precipitation; the phospholipins were then purified chromatographically on silica gel. Acid hydrolysis of the phospholipins, followed by steam distillation, yielded fatty acids which were subjected to gas-liquid chromatography.

The following acids, representing a total of 0·17 per cent. by weight of the total phospholipin fatty acids, were identified: acetic, octanoic, propionic, hexanoic, butyric, *iso*valeric and valeric, in decreasing amounts on a molar basis.—G. A. Garton.

1917

VAN DER GRIFT, J. Het kopergehalte van lever en bloedserum bij het Fries-Hollandse rund.

[The copper content of liver and blood serum of Friesian cattle.] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.10, pp. 61. [Rijkslandbouwproefstat., Hoorn.] English summary.

Serum Cu was estimated in samples from 346 cattle on about 90 farms in the late summer and autumn of 1951 and 1952. The range of values was wide : 12 per cent. were below 20 μg. per litre and 17·5 per cent. were above 81 μg. While values below 40 μg. per litre indicated Cu deficiency, many values between 60 and 80 mg. could not be improved by giving Cu, and serum Cu was not a sensitive indicator of Cu nutrition. Accordingly liver biopsy was used to obtain liver samples for Cu estimation. Two methods are described. Cu values obtained from biopsy samples agreed well with those from the whole liver after slaughter.

Monthly samples were taken from 7 calves from birth to about 19 months of age, and from 3 others starting at 3 months old. During the milk-feeding period the values, high at birth, fell so that the mean declined from 339 mg. per kg. dry liver at 1 day of age to 126 at 3 months and 150 at 5 months. During the first winter on stall feeding the values were then fairly constant and the mean at 11 months was 164 mg. per kg., but when the yearling animals went to pasture the values fell steeply, reaching 24 mg. per kg. when they were 17 months old and 8 mg. at 19 months, when 4 of the 7 were pregnant. During the first 5 months serum Cu rose from a mean of 45 μg. per 100 ml. at birth to 69, so there was no connection between serum Cu and liver stores. In 3 cows liver Cu values after parturition were 3·25, 18 and 210 mg. per kg. dry matter, and those of their calves 239, 316 and 447. The liver Cu stores of the calf thus depend on those of the mother. The liver Cu of pregnant cows fell sharply, especially in the last 2 months before calving.

Blood and liver Cu values were compared in 42 adult cows on 9 farms in 1953 and 1954. When liver Cu was below 25 mg. per kg. serum Cu was low, but when liver Cu exceeded 25 mg. per kg. serum Cu fluctuated about a mean of 85·3 $\pm$ 10·5 μg. per 100 ml., with extremes of 66 μg. with a liver Cu of 56 mg. per kg. and 103 μg. with a liver Cu of 570 mg. The probability that serum Cu values below 60 μg. are related to low liver Cu reserves is 0·05.

It is suggested that 75 per cent. of adult Friesian cattle in Holland have less than optimum Cu reserves.—D. Duncan.

GIACALONE, O. Ormoni e iponutrizione. **[Hormones and undernutrition.]** *Arch. Fisiol.*, 1955, **54**, 404–422. [Ist. Fisiol., Univ. Palermo.]

Adult male rats were maintained on a diet of, per cent., wheat starch 75, casein 10, butter 10 and Osborne and Mendel salt mixture 5, with vitamins. The amount was fixed and was such as to cause progressive loss of weight till death. Groups of 5 were given in addition thyroxine, adrenaline, insulin, thymus extract, extract of total adrenal cortex, extract of total anterior pituitary gland, testicular extract, ovarian extract, or no addition. Rate of loss of weight and time of survival did not differ greatly in the treated rats from those given no treatment. Decline was accelerated somewhat by thyroxine, adrenaline, thymus and testicular extract, but the other hormones had no effect.—E. M. Hume.

NÄGELE, E. Der primäre und der sekundäre Hyperparathyreoidismus. Über Beziehungen zwischen Epithelkörperchen, Nierenerkrankungen und Osteopathien. [**Primary and secondary hyperparathyroidism. Relations between the parathyroids, renal disorders and bone disorders.**] *Deutsch. med. Wochenschr.*, 1955, **80**, 1400–1405. [Med. Klin., Univ. Freiburg i. Br.]

Primary hyperparathyroidism is characterised by excessive production of parathyroid hormone, by changes in mineral metabolism and by renal calcinosis or calculi as a result of increased Ca excretion in the urine, and often by generalised skeletal demineralisation. It is usually caused by parathyroid adenoma, rarely by simple hyperplasia. There is increased excretion of P in urine and low blood P, and high serum Ca with its effects on the muscles and heart. Serum alkaline and acid phosphatases are increased. The condition affects most commonly women between 30 and 55 years old, with pain resembling rheumatism, skeletal deformation, spontaneous fractures or renal colic. It is curable by removal of the adenomatous gland. It is still uncertain whether classical von Recklinghausen's disease with low blood P and high Ca is primarily hyperparathyroidism or whether the increased parathyroid function is secondary to disturbed mineral metabolism.

Secondary hyperparathyroidism is recognisable because there is a basal disease, usually a severe chronic kidney disorder such as chronic interstitial nephritis, of long standing and with renal insufficiency. Less commonly the cause is rickets, osteomalacia or bone carcinoma, biliary fistula, general Ca deficiency due to increased requirement or insufficient intake, or multiple myeloma. In the secondary condition not only one or two, but all the parathyroids are hyperplastic. There is reduced excretion of P, high blood P, negative Ca balance and low serum Ca. There may be tubular renal calcinosis, which is, therefore, not a distinguishing characteristic of either form. Besides uniform skeletal decalcification there may be deposits of Ca in the lungs and other soft tissues. The condition is most common during the growing years; affected children are slow in growth and sexual development. They often have "late rickets". Removal of the parathyroids is seldom beneficial. A fatal case in a 16-year-old girl is described.—D. Duncan.

STUART, A. E. **The functional activity of thyroid nodules in an area of endemic goitre.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33**, 429–433. [Launceston Gen. Hosp., Tasmania.]

Endemic goitre in Northern Tasmania occurs in the form of colloidal or parenchymatous nodules. The functional activity of 19 of these nodules from 19 patients with non-toxic goitre was assessed. Each patient received about 150 μC. of ^{131}I intravenously 24 hr. before operation. After operation all glands were sectioned serially; one portion was reserved for the usual histological routine, and the radio-activity of the other portion was studied in autoradiographs.

The parenchymatous nodules had hardly any radio-activity and were said to have a low functional power. The colloid nodules were more active than the parenchymatous, but less active than normal thyroid tissue, and were generally classed as fairly inactive in non-toxic goitre. There was a fair amount of activity in one colloid nodule, and further investigation may show that such activity in a colloid nodule may be an early indication of thyrotoxicosis.—B. W. Simpson.

MARTIUS, C., BIELING, H. and NITZ-LITZOW, D. Vergleich der Wirkung von Thyroxin auf den Grundumsatz und die Atmungskettenphosphorylierung. [**Comparison of the effects of thyroxine on basal metabolism and respiratory phosphorylation.**] *Biochem. Ztschr.*, 1955, **327**, 163–169. [Physiol. Chem. Inst., Univ. Würzburg.] English summary.

Adult male guineapigs were kept at 20° C. and fed to appetite on a mixed diet including hay and roots or greenstuff. The rats were kept at 22° C. and fed on stock diet. Of pairs of similar animals, the rats usually littermates, one received several injections of thyroxine or triiodothyronine, the other saline. The animals were fasted for 18 hr. before estimations of B.M.R., and then diaphragm segments and preparations of liver mitochondria were used for study of oxygen and phosphate metabolism.

The degree of increase in the B.M.R. was quite close to the value calculated from the reduction in P : O ratios in diaphragm and liver mitochondria.

CARMINATI, G. M. L'azione dell'ormone galattogeno ipofisario nel coniglio e nel piccione. [**Effect of pituitary lactogenic hormone in the rabbit and the pigeon.**] *Arch. Sci. biol., Bologna*, 1955, **39,** 512–524. [Ist. Sieroterap. "S. Belfanti", Milan.]

Experiments were made on 102 pigeons and 173 rabbits.

In 15 rabbits given by injection 2·5 mg. oestrone daily for 7 days and 1 mg. progesterone daily for the next 5 days, pseudopregnancy was produced, but no milk was formed. In such rabbits purified preparations of prolactin regularly induced lactation in 4 days. The amount of prolactin necessary was from 32 to 48 times the amount needed to produce proliferation of the crop glands in pigeons. In terms of international units, the rabbits needed 64 to 96 and the pigeons 2. Lactation was produced also in 4 male rabbits pre-treated with oestrone and progesterone.

An impure preparation of pituitary lactogenic hormone elicited a positive response in 6 out of 47 pigeons and 27 out of 48 female rabbits, but not in 10 male rabbits. Other hormones may have been present in this preparation.—D. Duncan.

HOMBURGER, F. and PETTENGILL, O. **The protein anabolic and other effects of testosterone propionate in mice : effects of nutrition and interrelationship of biologic activities of the hormone.** *Endocrinology*, 1955, **57,** 296–301. [Cancer Res. Unit, Tufts Univ. Sch. Med., Boston, Mass.]

Immature female mice, 3 weeks old, received 2 mg. testosterone propionate in groundnut oil by subcutaneous injection on alternate days ; controls received oil alone. The mice received either a stock diet to appetite or the same diet restricted to the lowest voluntary intake of any group in that experiment, or a high-protein diet with 46·4 per cent. casein. After 27 days the mice were fasted for 24 hr. and were then killed. Carcase, clitoris, adrenal and kidneys were weighed fresh, carcase and one kidney after drying, β-glucuronidase was estimated in kidney homogenate and the rest of the kidney was studied histologically.

Mice of the Rockland Farms strain fed to appetite grew more quickly with testosterone than without, but this difference was not shown by mice on restricted or high-protein diets or those of the Tufts University strains. On all diets testosterone increased the weights of kidneys and clitoris and the β-glucuronidase activity of the kidney and reduced the size of the adrenals. The carcase contained more water after testosterone on the normal diet, but not on the high-protein diet.
D. Duncan.

DE GANDARIAS, J. M., SOLOAGA, A. and RECIO, J. M. Estudio experimental de la accion anabolica proteica de la testosterona. [**The**

protein-anabolic effect of testosterone.] *Rev. clín. española*, 1955, **58**, 211–217. [Inst. Español Fisiol. Bioquím., Valladolid.] English, German and French summaries.

Groups of adult rats of each sex were fed on a stock diet; one group of 7 of each sex received every second day an injection of testosterone propionate until 4 injections had been given. The doses differed from one rat to another. The rats were killed 2 days after the last injection. The results are given in tables.

The mean weight increases were for male controls 1·5 g., female controls 1·0 g., male injected rats 1·75 g. per mg. testosterone, female injected rats 1·10 g. per mg. testosterone. The corresponding values for serum protein were 4·69 and 4·49 g. per 100 ml. and increases of 0·25 and 0·14 g. per mg. testosterone injected. The mean increases in muscle protein were 2·49 and 1·27, in liver protein 0·44 and 1·5 and in spleen protein 1·04 and 1·90 g. per mg. testosterone.—D. Duncan.

MCKEE, J. P. and EICHORN, D. H. **The relation between metabolism and height and weight during adolescence.** *Child Development*, 1955, **26**, 205–212. [Univ. California, Berkeley.]

The 4 physiological indices examined for their relation to rate of growth in height and weight were B.M.R., total calories produced per hr., rate of change in B.M.R. and rate of change in total calories per hr. Measurements were made every 6 months between the ages of 11·5 and 17·5 years on 52 boys and 52 girls.

For both sexes rates of growth in height and weight were positively correlated with average B.M.R. and with rate of change in total calories produced per hr. For boys there was a significant negative correlation between average total calories produced per hr. and rate of growth in height and no correlation between average total calories per hr. and rate of growth in weight. For girls the two median coefficients were positive. This sex difference is attributed to the different timing of the growth spurts in height and weight in the two sexes.—F. C. Aitken.

1941

GROSSMAN, M. I. and SLOANE, H. S. **Some relations between body weight, body fat and calorie intake.** *Amer. J. Clin. Nutrit.*, 1955, **3**, 403–408. [U.S. Army Med. Nutrit. Lab., Denver, Colo.]

Total food intake by weighing, bodyweight, body fat, calculated from skinfold measurements, and total urine nitrogen were estimated for 87 soldiers. Experiments on different levels of energy intake and at different levels of activity were mostly made in one-week periods.

There was a positive correlation between energy intake and bodyweight (r = about 0·3). When body fat was taken into account the correlation was better; for a given bodyweight energy intake decreases with increasing body fatness. The loss of bodyweight during a period of food restriction was correlated with initial bodyweight but not with fatness.

Nitrogen excretion during food restriction was positively related to bodyweight. It was negatively correlated with body fat early in the experiment, but the relation disappeared later. A

formula for energy requirement based on bodyweight was derived from the data, but it appeared to have no better predictive value than that derived theoretically by the FAO Committee.

"Perhaps the point of greatest interest is that the correlation between calorie intake and bodyweight although statistically significant, is of low order, and that accurate prediction of calorie requirement requires the consideration of parameters in addition to bodyweight."

F. E. Hytten.

1942

WACHHOLDER, K. Über die obere und untere Grenze der optimalen Kalorienzufuhr. [**Upper and lower limits of optimum energy supply.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1463–1467. [Physiol. Inst., Univ. Bonn.]

The studies on which this discussion is based were made on groups of medical student cadets in army training and soldiers convalescent from war wounds. Such groups were uniformly fed, in respect of energy supply, for weeks or months, and were without the complications of civilian rations or sharing of food within the family. The convalescents represented "normal consumers" between 20 and 30 years of age in "sedentary" occupations. All attended as required at the laboratory for metabolism studies (see Absts. 1515, Vol. 15; 2247 and 5047, Vol. 19).

In men of 170 to 175 cm. height and 65 kg. weight in equilibrium on a diet of 2400 gross, 2200 net Cal. (*i.e.*, less loss in excreta), energy expenditure during the night was less by at least 30 Cal. than B.M.R. (Ruhe-Nüchtern-Umsatz). There are economies of basal expenditure and S.D.A. during work which might amount to 100 Cal. daily. With a basal expenditure of 1700 Cal. cost of rising, dressing, 130 Cal., of walking 3 km. to and from work, 100 Cal., of S.D.A., 200 Cal., there is a surplus of only 70 Cal. for work, which is inadequate; with the economies indicated, the surplus is 200 Cal. and adequate for light work.

Reduction of intake, with loss of weight and attainment of new equilibrium, may be carried as far as 1800 Cal. daily. When B.M.R. is reduced by 15 or 16 per cent. and there is no S.D.A., with complete rest (Zimmerruhe) weight equilibrium is possible on 1550 Cal. and with bed rest on 1450 Cal. But, up and about, disturbances of blood pressure and of the psyche occur at 1900 Cal.

Energy intake up to 2700 or 2800 Cal. causes little rise in B.M.R. and little or no increase in S.D.A., about 100 Cal. daily for both. The surplus over 2500 must be expended in exercise or deposited in fat.

The optimum range for "sedentary" workers is therefore judged to be 2150 to 2500 Cal. daily. Men who work standing and moving to and fro require 100 to 200 Cal. more. The U.S. National Research Council allowance of 3200 Cal. is dangerous in an industrial, highly mechanised society.

There is scarcely any comparable information for women; their B.M.R. is 10 per cent. less than that of men of the same height, weight and age. Little is known of S.D.A. or cost of work.

The estimate of Droese *et al.* (Abst. 5041, Vol. 19) for the housewife is "erstaunlich hoch"; but women tend to get fat, and not only after the climacteric.—I. Leitch.

DURNIN, J. V. G. A. and EDWARDS, R. G. **Pulmonary ventilation as an index of energy expenditure.** *Quart. J. Exp. Physiol.*, 1955, **40,** 370–377. [Inst. Physiol., Univ. Glasgow.]

The possibility of estimating energy expenditure from pulmonary ventilation was tested by analysis of data obtained in 2 field surveys (see Absts. 558, Vol. 23 and 943, Vol. 26). Regression equations of the type

Energy expenditure $= a \times$ Pulmonary ventilation

were calculated for 34 men. Six observations for each provided a sufficiently accurate measure of the relation if ventilation was above 15 litres per min. Below that rate the points tended to fall below the line. There is a discussion of the applicability of the technique to surveys of everyday activities in which ventilation is between 15 and 50 litres per min. and of its advantages over other methods requiring collection and analysis of expired air.—D. Harvey.

1945

MILLER, A. T. (Jr.) and BLYTH, C. S. **Influence of body type and body fat content on the metabolic cost of work.** *J. Appl. Physiol.*, 1955, **8,** 139–141. [Dept. Physiol., Sch. Med., Univ. N. Carolina, Chapel Hill.]

A gradient walking test was made on 30 healthy men, and their weight, height, fat content, chest circumference and abdominal circumference were measured. The total metabolic cost of the exercise, as measured by indirect calorimetry, was found to be linearly related to bodyweight and to be independent of the other measurements except as they were also related to bodyweight. This is in contrast with the basal metabolism, which is more closely related to lean body mass than to total bodyweight. The effect of obesity is therefore to increase energy requirement during exercise, and since the maximum oxygen intake is limited by the size of the lean body mass, tolerance of exercise is reduced.—I. McDonald.

1946

BEDFORD, T. and WARNER, C. G. **The energy expended while walking in stooping postures.** *Brit. J. Indust. Med.*, 1955, **12**, 290–295. [Med. Res. Counc. Environmental Hyg. Res. Unit, London Sch. Hyg. Trop. Med.]

Data were obtained by the Douglas and Haldane technique for 2 subjects who moved at different speeds in the half-stoop position, *i.e.*, with height reduced by 20 per cent., in the full-stoop position with 40 per cent. reduction in height, and on all fours. The costs were, at half stoop, from 30 to 50 per cent. above that of normal walking; in the full-stoop position and on all fours, respectively, 3¼ times and about 5 times that of normal walking. The work of Moss (Abst. 2890, Vol. 5) is considered to have underestimated the increase over the rate for normal walking which movement in these attitudes requires.—D. Harvey.

1947

KARVONEN, M. J. (with ALAVAINIO, K., ALLINEN, V., GRÖNROOS, I., KOKKO, J., KOSKELA, A., NUORVAARA, S., SAARIAHO, V., VILHUNEN, O. and ÖHMAN, I.] **Age and performance in athletics.** *Internat. Ztschr. angew. Physiol. Arbeitsphysiol.*, 1955, **16**, 110–119. [Inst. Occupational Health, Helsinki.]

For each of 20 track and field sports practised in Finland the ages of the 20 best sportsmen of each year from 1947 to 1953 were studied; for ball games the age data were found for 61 teams and 700 men; for skiing, for the 5 best Finnish participants in each of the 4 most important contests from 1931 to 1950; and for lumber work, for the participants in national woodcutting competitions in 1945 and 1951.

The ages are arranged in graphs and tables to show the mean age for best performance in each activity. The means range from 23·5 years for the 100-m. sprint to 34·2 years for the marathon. For running and skiing, the less speed and the more endurance is required the greater the mean age favoured. In sports where skill is essential older men are favoured, but the scatter of ages is high. No deduction should be made about changes in performance with age of the individual, since the performance of an athlete with increasing age does not deteriorate as steeply as his chances of remaining among the best 20 in his event.

PADUCHEVA, A. L. Dykhanie, gazoobmen i teploregulyatziya u karakul'skikh ovetz. [**Respiration, gaseous exchange and heat regulation in Karakul sheep.**] *Karakul. Zver.*, 1955, **8**, No. 2, 38–43. [All-Union Sci. Res. Inst. Animal Husb.]

At high air temperatures both respiratory rate and ventilation are increased 10 to 15 times. With rise in temperature breathing becomes more rapid, with means of 20 respirations per min. at 3° C. to 103 at 30° C. The ventilation, *i.e.*, the volume of air expelled in 1 min., increases on the average from 8 to 32 litres, with individual variations within the limits of 4 to 45 litres. The ventilation changes with drinking. A considerable amount of water drunk by a sheep, which may be as much as 7 litres on a hot day or 15 per cent. of the weight of the sheep, reduces body temperature by 1° to 1·5° C., which brings about a change in ventilation, first reducing it and then increasing it. Sheep adapt themselves to high temperatures mainly by less movement and increased rapidity of breathing.

In organising the summer care of sheep it is advisable in hot climates to limit their activity; they should be rested during the day and pastured at night.—H. Scherbatoff.

1950

LUDVIGSEN, J. and THORBEK, G. Virkningen af aureomycin på stofskiftet hos svin og stofskiftet hos galte og sogrise. Varmeproduktionen hos svin på forskellige alderstrin med saerlig henblik på staldventilation. [**The effect of aureomycin on the metabolism of pigs and metabolic processes in barrows and gilts. Heat production of pigs at different ages, with special reference to sty ventilation.**] *Forsøgslab. København. Beretn.*, 1955, No. 283, pp. 110. English and French summaries.

The study was made on 4 gilts (non-parous females) and 4 barrows (castrated males), 2 of each from 2 litters; 2 of each from the different litters acted as controls and the others were given 20 mg. aureomycin daily. They were fed on the rations normally used, of mixed cereals with 2·5 per cent. lucerne meal, a mineral mixture of Ca, P and NaCl, soya bean oil with 2000 I.U. vitamin A and 500 I.U. vitamin D_2 daily, and the equivalent of 1 litre skimmed milk as dried skimmed milk. Techniques are described and results presented in detail.

Balances of N, C and energy were computed from the results of chemical and respiratory metabolism experiments from 20 to 90 kg. weight. Aureomycin had no effect on the digestibility of dry matter but a significant effect on apparent digestion of N, possibly as the result of reduced

endogenous N excretion. On the average N balance was not affected because excretion in the urine rose. Aureomycin showed greater deposition of C in N-free compounds and, from the respiratory quotient, probably as fat. Total heat production was reduced, which implies more economical use of feed.

When gilts and male castrates were compared, absorption of N was the same but the males excreted more N in urine, so that gilts retained 4 g. N daily more than the males, a highly significant difference. They also deposited more C, but the males deposited more in fat. The R.Q. in the last stages of fattening was 1·256 for gilts and 1·267 for males. Total heat production was similar in the earlier part of the study, but later it was higher in males, by 200 Cal. daily in the last 2 months. For the controls over the weight range 20 to 90 kg. heat production may be computed as follows: oxygen consumption in litres = 6·5 × weight + 257; CO_2 production in litres = 9·2 × weight + 177 and heat in Cal. = 38·4 × weight + 1031. From this the total heat generated in a piggery may be computed.—I. Leitch.

BLINCOE, C. and BRODY, S. **34. The influence of diurnally variable temperatures on the thyroid activity and iodide metabolism of Jersey and Holstein cows.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 574, December 1954, pp. 31; No. 576, February 1955, pp. 36; No. 578, February 1955, pp. 26; No. 579, February 1955, pp. 12.

For previous parts see Abst. 5185, Vol. 25.

31. The animals used in this experiment were 4 lactating Jersey, 6 lactating Holstein and 2 dry Brahman cows. The effect of weekly exposure to radiation intensities from 0 to 500 Cal. per sq. m. per hr. at environmental temperatures of 45°, 70° and 80° F. was studied.

At 45° F. in all animals respiration rate, pulmonary ventilation rate and total evaporative cooling increased slightly with increasing radiation, but rectal temperatures and heat production remained normal.

At radiation intensity of 115 Cal. per sq. m. per hr. and 70° F. air temperature, rectal temperatures in one Jersey and 2 Holsteins began to rise, and at 480 Cal. they were 3½° F. above normal. In one Jersey and 2 Holsteins they rose 1½° F. above normal, and in the rest of the animals there was no change. Heat production was unaffected in the Brahmans, but was reduced by 12 per cent. in the Jerseys and 26 per cent. in the Holsteins. At air temperature 80° F. rectal temperature increased by up to 5° F. in all the European cattle as radiation increased. The increase in most of the Jerseys was much less than in the Holsteins, indicating that the smaller breed was showing less heat strain. Respiratory vaporisation increased continuously with increasing radiation, but skin vaporisation reached a plateau at 360 Cal. per sq. m. per hr. The rate of heat production of the Brahman was only half that of the other breeds, which would partly explain the greater heat tolerance of the Brahmans. It was estimated that the heat stress of 500 Cal. per sq. m. per hr. radiation at 70° F. air temperature was equivalent to an increase of 10° F. in air temperature without radiation.

32. Thyroid activity and iodide metabolism in Jersey, Holstein, Brown Swiss and Brahman cattle was studied with ^{131}I in different conditions of environmental temperature, air velocity, radiation intensity and starvation.

When ambient temperature was above 95° F., the limit of the comfort zone, thyroid activity was decreased, most in Holsteins, least in Brahmans. When temperature was below 32° F., thyroid activity in Brahmans and Jerseys increased by 60 to 100 per cent., but Holsteins and Brown Swiss were not similarly affected.

Air velocity from 0·5 to 10 m.p.h. did not affect any cattle when environmental temperature was between 32° and 80° F. Radiation intensity of 488 Cal. per sq. m. per hr. at 70° to 80° F. air temperature increased thyroid activity in European breeds, but not in Brahmans. Starvation for 4 days reduced thyroid activity in Holsteins.

Total iodine metabolism, estimated from rate of clearance of plasma iodide, was not affected by the climatic conditions imposed. Increasing heat stress decreased the percentage of the dose of ^{131}I excreted in milk but slightly increased the concentration.

33. The effects of diurnal changes in temperature on milk yield, feed and water intake of 3 Jersey and 3 Holstein cows were studied. The temperature ranges were chosen to simulate conditions in different regions.

No effect was observed of the 40° to 70° F. range, which was therefore assumed to be optimum. In the low ranges yield was slightly depressed in Jerseys, but not in Holsteins. In both breeds yield in the 70° to 100° F. range declined, 20 per cent. in Holstein and 8 per cent. in Jerseys; a decline of not more than 6 per cent. was due to advancing lactation. Feed consumption was also reduced by 20 to 30 per cent. in Holsteins, but very little in Jerseys. After a week in this temperature range there were indications that the animals were becoming acclimatised, with consequent improvement in performance.

The effect of range 50° to 110° F. was less than that of 70° to 100° F., and no effect of range 40° to 110° F. was recorded. This supports the theory that the number of hours spent in cooling temperatures, below 70° F., and the number spent in heating temperatures, above 80° F., are as important as the maximum and minimum temperatures in physiological effect.

The range 40° to 70° F. produced the same effect as constant temperatures between 40° and 60° F. and the range 70° to 100° F. was comparable to a constant temperature of 85° F.

34. The effect of diurnal change in temperature within different ranges was studied. Variations within the range 10° to 40° F. increased thyroid activity by 20 per cent. compared to that in the range 40° to 70° F. In the range 70° to 100° F. thyroid activity was reduced 30 per cent. No effect on iodine metabolism was found.

ISAAKYAN, L. A. O sezonnykh izmeneniyakh khimicheskoi termoregulyatzii i spetzifichesk-ogo dinamicheskogo deistviya peshchi u geterotermnykh zhivotnykh. [**Seasonal changes in chemical thermoregulation and specific dynamic action of food in heterothermic animals.**] *Fiziol. Zh. SSSR Sechenova*, 1955, **41**, 210. [Inst. Eksp. Med., Akad. Med. Nauk SSSR, Leningrad.]

By measuring body temperature and gaseous metabolism, a study was made over the course of a year of changes in thermoregulation in the hedgehog and the suslik (*Spermophilus* sp., pouched marmot), and as a control in the laboratory white rat.

In the hedgehog the intensity of the processes involved in chemical heat regulation diminished in autumn, and in the winter this faculty was in total abeyance. In the suslik the processes were insufficient to maintain body temperature in autumn and winter, although metabolism did increase in response to lower environmental temperature. In both species the specific dynamic action of food, apparent in spring and summer, became much less in autumn and winter. These seasonal changes were not found in the rat. The results, it is considered, uphold the view that nervous reflex mechanisms play an important part in the determination of the response of heterothermic animals to temperature changes.

MELLEN, W. J. and HILL, F. W. **Studies of the avian respiratory quotient.** *Poultry Sci.*, 1955, **34**, 1085–1089. [Dept. Poultry Husb., Cornell Univ., Ithaca, N.Y.]

Respiratory quotients of chickens of different ages were estimated in a Haldane apparatus (*J. Physiol.*, 1892, **13**, 419). For young birds groups were studied together, so the values were means.

The range of fasting values was from 0·65 to 0·88 in the first experiment, and the largest proportion of values below 0·70 was obtained in larger birds fasted for 38 to 46 hr. A series of estimations on a group of birds when they were $2\frac{1}{2}$, $3\frac{1}{2}$, $4\frac{1}{2}$, $5\frac{1}{2}$ and $7\frac{1}{2}$ weeks old showed a slight mean fall, of doubtful significance, in R.Q. There was no difference with increased fasting times of between 24 and 54 hr.

In 1 pullet there was an increase in R.Q. from 0·74 to 0·81 one and a half hr. after ingestion of 5 g. glucose. In 3 other pullets neither casein nor olive oil significantly affected the R.Q.

CARBOHYDRATES

1956

CLAYTON, M. M. and RANDALL, S. W. **Blood changes following breakfasts of different types. Blood sugar and chylomicrons in young women of different weights.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 876–882. [Dept. Home Econ., Maine Agric. Exp. Stat., Orono.]

For 2 years 24 young women aged 17 to 29 years and weighing from 114·8 to 193·5 lb. received one of 3 breakfasts providing about 450 Cal.; the high-fat breakfast contained 30·9 g. fat, 8·2 g. protein and 41·2 g. carbohydrate, the high-protein breakfast 23·2 g. protein, 19·5 g. fat and 45·8 g. carbohydrate and the high-carbohydrate breakfast 83·4 g. carbohydrate, 7·5 g. protein and 11·1 g. fat. Finger blood samples were taken before breakfast and 30 min., 2 hr., 3 hr. and 4 hr. after breakfast. Chylomicron counts and glucose estimations were made on each serum sample. Before or after the breakfast tests the subjects kept records of all food eaten for 1 week.

For the whole group of 24 subjects the highest average chylomicron counts were at the third hour after high-fat and high-protein breakfasts. After the high-protein breakfast the average blood sugar remained above the fasting level during the fourth hour; after the high-fat and high-carbohydrate breakfasts, the average fell below the fasting level at the second and third hours. The greatest average drop in blood sugar occurred at the third hour after the high-carbohydrate breakfast. The group was divided into the 12 heaviest and the 12 lightest subjects; for the heaviest subjects the average blood sugar fell below the fasting level at the third hour after the high-carbohydrate breakfast. The average values did not fall below fasting for either group after the high-protein breakfast. After the high-fat breakfast, the average values fell below fasting at the second or third hour, but did not fall as low as those of the heaviest group after the high-carbohydrate breakfast. The breakfasts ordinarily eaten by the 21 heaviest subjects provided more energy and protein than those eaten by the 12 subjects weighing the least.

Of the 3 breakfasts studied, the high-protein breakfast was the most satisfactory for preventing hunger among all 24 subjects.—G. F. Garton.

CONARD, V. Mesure de l'assimilation du glucose. Bases théoriques et applications cliniques. **[Measuring the assimilation of glucose. Theoretical basis and clinical applications.]** *Acta gastro-enterol. belg.*, 1955, **18,** 655–705; 727–771; 803–845. [Clin. Méd., Hôp. Brugmann, Brussels.]

See also Abst. 4539, Vol. 23.

The chemistry of carbohydrate metabolism is discussed briefly. The work attempts to isolate, from the group of phenomena which determine the course of the blood sugar curve after an intravenous dose of glucose, the role of assimilation, defined as the active passage of glucose from the extracellular fluids into the cells. When the blood sugar is below the threshold at which sugar appears in the urine, its rate of fall depends on assimilation alone. Assimilation is regulated by the level of the blood sugar itself (Wierzuchowski, Abst. 3429, Vol. 7) and by the endocrine balance, particularly the amount of insulin available to control the transfer of glucose across the cell membrane (Stadie, *Physiol. Rev.*, 1954, **34,** 52). If the postulate be accepted that the transfer of glucose from one compartment to the other is the critical stage in its metabolism, free glucose can be considered as an extracellular substance, and for a study of the rate of assimilation it is necessary to know the volume of interstitial fluid.

Intravenous blood sugar tolerance tests with a single dose of glucose, 0·66 ml. of 50 per cent. solution per kg. bodyweight, were made on 400 subjects, mostly in hospital. Some subjects received insulin, 0·1 unit per kg. Repeated experiments of the same type were made on dogs. The middle part of the blood sugar curves, from the 10th to the 60th minute, was used for comparative purposes to avoid errors in the earlier and later values. The curves from 15 normal young subjects were studied statistically.

Simultaneous injections of glucose and thiocyanate, for estimation of extracellular fluid, were given to 97 subjects. The fall in blood sugar concentration corresponding to the slowest exponential of the curve expresses in a simple form glucose assimilation. If the amount of glucose injected is divided by the thiocyanate volume it is possible to calculate the peak which will be reached by the blood sugar if the glucose remains extracellular. Extrapolation of the middle part of the blood sugar curve to time of injection gives a value corresponding to the calculated one. Therefore assimilation can be expressed by the simple exponential equation $C = Ae^{-Kt}$ or $\log C = \log A - Kt$, where A and K are constants and C is the blood sugar concentration at time t. The determination of A and K is based on the fact that the semilogarithmic representation of this equation, with time as abscissa and log of concentration as ordinate, is a straight line, with $\log A$

as its intercept on the y axis and $-K$ as slope. The volume of diffusion calculated from A is close to other estimates of extracellular space, in man about 25 per cent. of bodyweight. K measures the rate of disappearance of injected glucose and is called the coefficient of glucose assimilation. The mean coefficient in 75 normal subjects was 1·74; in 90 diabetic subjects it was 0·54, in 21 subjects aged more than 60 years it was 0·99, and in 55 subjects with reduced assimilation 1·01. Administration of insulin raised the value of K to a mean of 5·87, and the values found in a subject with pancreatic cancer were 3·20 and 4·47. Cortisone given for several days raised the value, which was also high in 9 out of 17 pregnant women, with a mean for all 17 of 2·28.

It is concluded that the rate of disappearance of glucose measures directly the avidity of the tissues and probably the insulin status of the cell membranes. The clinical applications of the findings are discussed.—D. Duncan.

CREUTZFELDT, W. and TECKLENBORG, E. Experimentelle Untersuchungen zur Funktion der A-Zellen der Pankreasinseln und zur Glucagonwirkung. [**Experimental investigation of the function of the alpha cells of the pancreatic islets and on the action of glucagon.**] *Arch. exp. Pathol. Pharmakol.*, 1955, **227**, 23–61. [Med. Klin., Univ. Freiburg i. Br.]

The experimental animals were 136 guineapigs weighing 400 to 550 g., 44 rabbits of 1·5 to 2 kg. and 39 rats of about 200 g., all fed on stock diets.

In guineapigs, Synthalin (decamethylenediguanidine) at 6 mg. per kg. bodyweight caused degranulation and perhaps vacuolisation of pancreatic alpha cells, but not so clearly as daily injection of 3 mg. per kg. subcutaneously, when the animals died after about $2\frac{1}{2}$ days. The nuclei of the alpha cells were then often pale and poor in chromatin, and the cells were enlarged. Beta cells were seldom affected. There was liver damage. In liver damage produced by phosphorus, CCl_4, chloroform or ethionine there were similar effects on the pancreatic cells, but not when liver damage was due to allyl formate or to scurvy. Glucagon did not prevent damage to the pancreas caused by $CoCl_2$, Synthalin or P.

In rabbits the pancreatic damage caused by Synthalin was not related to the fall in the blood sugar. Glucogon could not counteract the effects of Synthalin. Low blood sugar produced by Synthalin cannot be explained as an effect of insulin after elimination of the alpha cells.

p-Aminobenzolesulphonamido*iso*propylthiodiazole caused damage to the alpha cells which differed from the damage due to Synthalin. Again there was no relation between cell damage and the fall in blood sugar.—D. Duncan.

ENGLHARDT-GÖLKEL, A. and BETZ, B. Über das Verhalten der Blutphosphate nach Glucose- und Fructosebelastungen. [**Behaviour of blood phosphates after administration of glucose or fructose.**] *Ztschr. ges. exp. Med.*, 1955, **126**, 214–219. [Med. Poliklin., Univ. Munich.]

Total P and its fractions were estimated in the blood of 10 fasting subjects, not more than 30 years old, after injection of 0·25 g. glucose or fructose per kg. bodyweight.

In the first 15 min. after injection fructose disappeared from the blood more quickly than glucose, and after fructose the fall in P was greatest. Organic and inorganic P curves were parallel. It is concluded that the loss of P was in the poorly hydrolysable fraction, and the significance of this is discussed.—D. Duncan.

1961

PROSIEGEL, R., STUHLFAUTH, K. and ENGLHARDT-GÖLKEL, A. Die Wirkung von Kohlenhydraten auf den Kaliumstoffwechsel bei Gesunden und Leberkranken. [**Effect of carbohydrates on potassium metabolism of healthy subjects and subjects with liver diseases.**] *Klin. Wochenschr.*, 1955, **33**, 799–803. [Med. Poliklin., Univ. Munich.]

In 13 healthy subjects given by rapid intravenous injection 0·25 g. per kg. bodyweight of glucose or fructose there was no constant change in serum K after either sugar. The blood inorganic phosphate fell after both sugars, but more rapidly and to a greater degree after fructose. The rise in the blood sugar was less after fructose than after glucose. In 11 healthy subjects and 10 patients with liver disease K in both arterial and venous serum was estimated after an initial injection of 16 g. and during an infusion lasting an hour of 100 g. of either sugar. In normal subjects there was a slight but definite fall in K in both sera after glucose, but a significantly greater fall after fructose, when the arterio-venous difference was increased as the sugar in arterial serum fell by from 4 to 8 mg. per cent. and in the venous serum by only half that amount. The inorganic P also fell more rapidly after fructose than after glucose, but there was no appreciable difference between arterial and venous values. In liver disease

similar changes occurred, but the falls in K and inorganic P after fructose were much less than in normal subjects. After glucose the changes in K and inorganic P were so small that there was no significant difference between the values for normal and abnormal subjects. The blood sugar curves after fructose did not suggest disturbance of storage capacity in the liver. The results are discussed in relation to cell enzyme systems in the peripheral tissues and the liver.—L. Wills.

KARYAKINA, V. A. Vzanmosvyaz glyukozy, molochnoi kisloty i fosfatov krovi ovetz v protzesse mezhutochnogo uglevodnogo obmena pri nekotorykh fiziologicheskikh sostoyaniyakh. [**Interrelations of glucose, lactic acid and phosphates of sheep's blood in intermediary metabolism of carbohydrate in some physiological conditions.**] *Biokhimiya*, 1955, **20**, 377. [Inst. Biol., Ural Filial. Akad. Nauk SSSR, Sverdlovsk.]

Blood samples from sheep with cannulae in carotid artery and portal vein were taken at short intervals before and after feeding and analysed for glucose, lactic acid and phosphate. Comparison of arterial and venous values showed that when the stomach was empty, glucose left the blood and lactic acid and phosphate were added, owing to utilisation of endogenous glucose. During the absorption of oat carbohydrate, beginning about 3 hr. after the food was given, the venous blood sugar exceeded the arterial, and venous blood phosphate and lactic acid increased also. Carotid artery and jugular vein blood samples were analysed during chloral hydrate anaesthesia. Sugar, lactate and phosphate all decreased in both arterial and venous blood, suggesting decreased glycolysis accompanying inhibition in the central nervous system.—D. W. Taylor.

PAGÉ, É., BABINEAU, L. M. and LACHANGE, J. P. **Carbohydrate utilization in rats adapted to cold.** *Rev. canad. Biol.*, 1955, **14**, 144–151. [Dept. Physiol. Nutrit., Laval Univ., Quebec.] French summary.

Absorption of glucose was measured by giving known amounts by stomach tube or by intraperitoneal injection to rats after a fast of 26 hr. The animals were killed 2 hr. later and the glycogen content of the liver and carcase was estimated. In rats which had been kept at least 38 days in a cold room at 8° ± 2° C. and had received a diet containing 75 per cent. sucrose, higher values were obtained for fasting liver glycogen, intestinal absorption of glycogen and deposition of liver glycogen than in comparable animals kept at normal room temperature. Glucose was less rapidly absorbed and allowed less deposition of liver and tissue glycogen when it was given intraperitoneally than when it was given by mouth.

INGLE, D. J., MORLEY, E. H. and STETTEN, D. (Jr.) (with SCHROEDER, E. and KLYBAS, V.). **Metabolism of glucose in resting and working rats.** *Amer. J. Physiol.*, 1955, **182**, 263–266. [Res. Labs., Upjohn Company, Kalamazoo, Mich.]

Glucosuria was induced in rats by continuous intravenous infusion of ^{14}C-glucose for 12 hr. Muscle work produced by electrical stimulation of either hind leg, or both, suppressed excretion of urine and storage of glucose in the liver. Work increased the amount of labelled glucose oxidised and the amount of unlabelled CO_2 expired and decreased the respiratory quotient.—A. Hepburn.

1965

CIANCIMINO, M. C., GIACALONE, O. and RUBINO, F. L'utilizzazione del glicidi nei ratti alimentati con dieta steatogena contenente grasso di bue o grasso di maiale. [**Utilisation of carbohydrate by rats fed on a diet to produce fatty liver and containing beef fat or pig fat.**] *Arch. Fisiol.*, 1955, **54**, 396–403. [Ist. Fisiol., Univ. Palermo.]

Of 30 male rats, 12 were given a diet of, per cent., sucrose 48, lard 40, casein 5, salt mixture 5 and sawdust 2, with vitamins, and 12 were given the same diet with beef fat instead of lard. Six were given stock diet. Six rats on each experimental diet were maintained for 24 days and 6 for 42. At the end of that time the rats fasted for 6 hr., and the respiratory quotient was estimated before and after administration of glucose. The rats were then given sucrose only for 30 hr., and the R.Q. was estimated before and after glucose again.

The R.Q. of the rats fed on stock diet rose after glucose and still more when the glucose was given after sucrose. In the rats given the experimental diets for 24 days there was no increase in R.Q. after glucose, but there was an increase in both groups when sucrose had been given. In the rats having the experimental diets for 42 days there was an increase after glucose and a further increase after glucose when sucrose had been given, but the increase was not as great as with the rats on stock diet. The increase was greater with the diet containing lard than with that containing beef fat, the latter having been shown to produce the more severe fatty liver (Abst. 5295, Vol. 25).

WOOD, H. G. **Significance of alternate pathways in the metabolism of glucose.** *Physiol. Rev.*, 1955, **35**, 841–859. [Dept. Biochem., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

1967

FOURNIER, M. P. L'action ostéogène de l'acide glycolique et ses conséquences. [**Osteogenic action of glycolic acid and its effects.**] *C.R. Acad. Sci.*, 1955, **240,** 2555–2557.

In support of the suggestion that "structural" carbohydrates exert their effect on Ca metabolism because they are precursors of glycine (Abst. 5195, Vol. 25), the value of glycolic acid was tested in the same way. Glycolic acid at the 1·5 per cent. level improved the utilisation of Ca by young rats as much as 10 per cent. of lactose.

It is postulated that glycolic acid, found in plant and animal tissues, may be the di-carbon molecule from which either "structural" carbohydrates or glycine can be built up.—D. Duncan.

1968

FOURNIER, P. De l'action commune, ostéogène et lipotrope, de la choline et du lactose. [**The osteogenic and lipotropic action common to choline and lactose.**] *C.R. Acad. Sci.*, 1955, **241,** 903–905.

The method was that described in Abst. 745, Vol. 25, but the substances included in the experimental diets at the expense of starch were 12 per cent. lactose or 2 per cent. choline chloride.

The coefficients of utilisation of Ca were with starch alone 21, with lactose 37 and with choline 39 per cent.

Other work which suggests a similarity in effects of lactose and choline is mentioned (Absts. 3124, Vol. 5; 911, Vol. 18), and the relation of both substances to glycine is discussed (Abst. 5195, Vol. 25).—D. Duncan.

1969

FOURNIER, P., DUPUIS, Y. and SUSBIELLE, H. Action du sorbitol et du mannitol sur l'ossification. [**Effect of sorbitol and mannitol on ossification.**] *C.R. Soc. Biol.*, 1955, **149,** 945–948. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

The method and basal diet resembled those used earlier (see, *e.g.*, Abst. 745, Vol. 25). The diets compared contained 6 per cent. glucose, sorbitol, mannose or mannitol, with starch to 81·5 per cent. as in the control diet.

Sorbitol, mannose and mannitol each increased the coefficient of utilisation of Ca from 18 per cent. with starch alone to about 35 per cent. No sorbitol, and only about 4 per cent. of the mannitol intake, appeared in the urine. Thus, both the derivative of the "energetic" sugar glucose and that of the "structural" sugar mannose exhibit the "structural" effect on Ca metabolism.

D. Duncan.

1970

FOURNIER, P., DUPUIS, Y. and SUSBIELLE, H. Les effets du dulcitol et de l'acide mucique sur l'utilisation du calcium. [**Effect of dulcitol and of mucic acid on calcium utilisation.**] *C.R. Soc. Biol.*, 1955, **149,** 1168–1170. [Lab. Physiol. Nutrit., École Hautes-Études, Paris.]

When tested by the method described in Abst. 745, Vol. 25, dulcitol at the rate of 6 per cent. of the diet had a favourable effect on Ca utilisation comparable to that of galactose. Mucic acid at the same level almost completely prevented the utilisation of dietary Ca, perhaps by the formation of calcium mucinate, which is nearly insoluble in water.—D. Duncan.

1971

PATTERSON, J. W. **Cataractogenic sugars.** *Arch. Biochem. Biophys.*, 1955, **58,** 24–30. [Dept. Anat., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

D-Galactose or D-xylose or L-arabinose given simultaneously or alternating with a diet containing D-galactose and dog chow accelerated the development of cataracts in rats. Their effectiveness decreased in that order and was proportional to the increase in blood sugar. Each has the same configuration at carbon atoms 2 and 3 and forms a ring through carbon atom 1, with a resulting equilibrium of α- and β-forms. D-Sorbitol, D-mannose and D-arabinose did not produce cataracts. Diabetic rats developed cataracts more quickly when they received 20 per cent. D-xylose, but D-xylose alone did not produce cataracts in normal rats.—A. Hepburn.

1972

SCHWARZ, V. and GOLBERG, L. **Galactose 1-phosphate in galactose cataract.** *Biochim. biophys. Acta*, 1955, **18,** 310–311. [Dept. Pathol., Univ. Manchester.]

Young rats weighing 50 to 60 g. received similar diets with and without 30 per cent. galactose. After from 46 to 92 days they were killed and whole lenses and lens capsules were analysed for galactose and its 1-phosphate.

Normal lenses contained no galactose. Normal capsules contained up to 0·08 μg. galactose 1-phosphate per capsule. In cataractous lenses the galactose seemed to be confined to the capsule, in which the concentration was at least 17 mg. galactose 1-phosphate per 100 g. tissue. Clear lenses from animals given galactose were comparable to normal lenses in galactose content. The amount of galactose 1-phosphate in cataractous capsules was of the same order as in red cells of infants with galactosaemia (Schwarz *et al.*, *Biochem. J.*, 1955, **59,** xxii).—D. Duncan.

1973

EL HAWARY, M. F. S. **Blood keto acid levels during intoxication with inhibitors of carbohydrate metabolism.** *Biochem. J.*, 1955, **61,** 348–352. [Dept. Chem. Pathol., Guy's Hosp. Med. Sch., London.]

Blood sugar, total keto-acids, pyruvate, α-oxoglutarate and acetone bodies were estimated in normal rats and in rats poisoned with arsenite, maleate, iodoacetate, alloxan, malonate or fluoride.

No abnormal keto-acid was found. Pyruvate and α-oxoglutarate were significantly increased in all the poisoned rats, pyruvate less so except with arsenate. Acetone bodies were slightly increased by arsenite, maleate, iodoacetate and fluoride, but were 8 times the normal value with malonate and 20 times with alloxan. In poisoned animals injected with sodium pyruvate the blood pyruvate failed to fall to normal within 30 min., as it did in intact rats.—D. Duncan.

BAUMGARTEN, F. Papierchromatographische Untersuchungen über die Zusammensetzung des Blut- und Harnzuckers von Gesunden und Diabetikern. [**Paper chromatography studies of the composition of blood and urine sugar in healthy subjects and diabetics.**] *Deutsch. Ztschr. Verdaungs- u. Stoffwechselkr.*, 1955, **15,** 198–210. [2. Med. Klin., Univ. Munich.]

A method of ascending paper chromatography, suitable for the clinical laboratory, for detecting small amounts (a few micrograms) of sugars other than glucose in blood and urine is described in detail. The solvents used were a mixture of phenol and glacial acetic acid, which gives good separation of glucose and fructose, or one of ethyl acetate, pyridine and water, which is less good for separating glucose and fructose but more effective for many other sugars; and for development, ammoniacal silver nitrate, triphenyltetrazolium chloride, benzidine or naphthoresorcinol. Rough but not exact estimation of the amounts present was possible.

Fructose was generally detected in the blood of healthy persons and, in some, lactose, inositol, a substance believed to be galacturonic acid, and rapidly moving substances believed to be pentoses. All were more prominent in the blood of diabetic persons. Only traces of substances giving sugar reactions were found in normal urine. The findings tabulated for the urine of 37 diabetic persons showed that most contained fructose, inositol and the supposed glucuronic acid and pentoses, and the amounts tended to be higher in those with severer glycosuria.—W. M. Deans.

1975

ZICKEFOOSE, J., HARDIN, R. C., TUTTLE, W. W., DAUM, K. and SALZANO, J. **Effect of breakfast and source of protein on blood sugar level of patients with diabetes.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1016–1019. [Dept. Nutrit., State Univ. Iowa Coll. Med., Iowa City.]

Twelve diabetic patients of both sexes between the ages of 29 and 81 years, who were maintained on NPH insulin and a daily intake of about 1800 Cal. from 200 g. carbohydrate, 90 g. protein and 80 g. fat, were given breakfasts containing 25 g. protein of either animal or plant origin on 3 consecutive mornings; blood sugar was estimated before the third breakfast and every ½ hr. after it for 3½ hr.

After both types of breakfast the blood sugar was significantly above the fasting level for 2½ hr. At 3 hr. the blood sugar had returned to a level not significantly different from the fasting level. It is concluded that proteins of animal and plant origin have an almost identical effect on blood sugar in diabetes.—G. F. Garton.

ARDY, C. and MONTINI, T. Influenza del lievito sulla funzionalità epatica del diabetica. [**Effect of yeast on hepatic function in diabetes.**] *Arch. Fisiol.*, 1955, **54,** 348–355. [Ist. Fisiol., Univ. Genoa.]

Ten moderately severe diabetics stabilised with insulin were given 10 g. dried yeast twice daily for 30 days. After treatment there was lower fasting blood sugar, less sugar in the urine, and less total fat, total and esterified cholesterol and bilirubin in the blood. There was improvement in the results of the liver function tests and increase in the phospholipins in the blood. When the blood sugar curve was recorded for 3 hr. after administration of glucose, it rose less high after administration of yeast.—E. M. Hume.

VARTIAINEN, I. and TELKKÄ, A. **Experiments in feeding normal rats on diets selected by diabetic**

rats. *Ann. Med. int. Fenn.*, 1955, **44**, 165–170. [2. Med. Clin., Univ. Helsinki.]

Five groups of rats were given diets containing, per cent., sucrose 80, or sucrose 10 and lactose 20, or lactose 30, or the diet high, and one of those low, in carbohydrate in alternate weeks. The high-sucrose diet was that previously selected by normal rats, and the one of lower carbohydrate content was that selected by rats with alloxan diabetes. In the present experiment the diets were given for 16 months, at the end of which no histological difference could be demonstrated in the pancreas, liver, kidneys, adrenal, thyroid and crystalline lens of the different groups. A further group which received 80 per cent. lactose in the diet developed cataract within 7 months. No sulphydryl compound could be demonstrated histochemically in the lenses of the rats on high lactose intake.—A. M. Copping.

FABRYKANT, M. (with ALLEN, J. F.) **The problem of functional hyperinsulinism or functional hypoglycemia attributed to nervous causes. 1. Laboratory and clinical correlations. 2. Dietary and neurogenic factors. Diagnostic and therapeutic suggestions.** *Metabolism*, 1955, **4**, 469–479; 480–490. [Dept. Med., Post-Grad. Med. Sch., Univ. New York.]

1. Oral glucose tolerance tests were made on 50 patients who presented the clinical picture of hypoglycaemia of nervous origin. In 58 tests, low blood sugar curves were recorded in 29, that is, low or normal initial rise, normal peaks and a fall to below 60 mg. per 100 ml. Normal curves were found in 6, and initially high curves in 23. None of the subjects with initially high curves and high peaks had clinical evidence of diabetes. In 31 of the 50 patients there was clinical diagnosis of conditions which could account for the hypoglycaemic symptoms; 9 had hypothyroidism. The clinical symptoms of the patients were reproduced in 29 out of 39 tests on these 31 subjects and in only 8 out of 19 tests on subjects without other conditions thought to predispose to the symptoms. In 6 patients who had 2 tests without a change of diet, 2 complained of symptoms in one test, but had only non-specific symptoms in the other. The extent of the fall of blood sugar during the tests was not related to the clinical condition.

It is concluded that functional hypoglycaemia attributed to nervous causes is not a clinical entity.

2. Low-carbohydrate diets with high protein and adequate fat were given to 3 of the patients discussed above, and to one with grand mal epilepsy but no spontaneous hypoglycaemic symptoms. Falls of blood sugar to below 50 mg. per 100 ml. were found in 3 out of 5 tests; in one patient the fall was greater than after a carbohydrate-rich diet.

In most patients of the series of 50, diets providing 50 to 100 g. carbohydrate, 120 to 140 g. protein and enough fat to cover energy needs produced an improvement in clinical complaints, but usually other treatment, especially sedation, was needed also.

The origin of the condition is discussed. It is concluded that the terms "functional hyperinsulinism" and "functional hypoglycaemia of nervous origin" should be dropped and that patients with these symptoms should be studied until the etiology of the complaint is more clearly defined. Treatment recommended includes frequent meals, high-protein diet, sedation, treatment of associated conditions and, where necessary, psychotherapy or surgery for suspected islet tumours.—D. Duncan.

HÖPKER, W. Das Verhalten der Blutketone in der protrahierten Hypoglykämie bei Ratten. [**Behaviour of blood ketones in prolonged hypoglycaemia in rats.**] *Ztschr. ges. exp. Med.*, 1955, **126**, 235–243. [Diabetesforschungsinst. Karlsburg, Greifswald.]

Ten rats fasted for 18 to 27 hr. received up to 1 unit insulin per 100 g. bodyweight, and 3 rats received twice this dose. When the rats died in hypoglycaemic coma, blood sugar and acetone and liver-glycogen were estimated. Other rats were killed after fasting for 15 to 30 hr. or after large doses of alloxan.

Normal rats had 1·2 to 2·0 mg. acetone per 100 ml. blood. The values rose during fasting, reaching 3 times the normal after 30 hr. Blood sugar was about normal and liver glycogen low. After insulin, acetone values were about normal, blood sugar extremely low and liver glycogen low. In rats which died in diabetic coma within 24 hr. after their last injection of alloxan, blood sugar was very high, and so was blood acetone, but in alloxan-resistant rats acetone did not rise. Acetone values were 10 or 20 times as high in diabetic coma as in hypoglycaemic coma.

It is concluded that the sugar supply of the sugar-sensitive centres is responsible for the occurrence of ketosis.—D. Duncan.

PARK, C. R. and JOHNSON, L. H. **Effect of insulin on transport of glucose and galactose into cells of rat muscle and brain.** *Amer. J. Physiol.*, 1955, **182,** 17–23. [Dept. Physiol., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Rats were eviscerated to eliminate insulin secretion and were then given a continuous infusion of glucose at rates of from 0·3 to 9·0 mg. per g. bodyweight hourly, with or without insulin. Insulin greatly accelerated the utilisation of glucose. Free glucose in the muscles was always low in proportion to blood glucose, but was higher, both absolutely and relatively, with insulin than without. Glucose accumulated similarly in the muscle of intact and of alloxan-diabetic rats given insulin.

In eviscerated rats infused for 25 min. with galactose, insulin increased the rate of disappearance of galactose from the blood; galactose concentration was increased in muscle, but not in brain. When galactose was infused for 135 min. there was still an effect of insulin in muscle; galactose reached high concentrations in the brain whether insulin was given or not.

In muscle, glucose and galactose were mainly extracellular without insulin, intracellular with it. Brain galactose was always to a large extent intracellular. It is concluded that insulin accelerates the passage of glucose and galactose across cell membranes in muscle, but not in brain.

NICHOLS, N. **The effect of glycogen deposition on liver phosphorus.** *J. Clin. Invest.*, 1955, **34,** 1710–1718. [Baker Clin. Res. Lab., New England Deaconess Hosp., Boston, Mass.]

There were 15 rabbits in the experiment: 4 were normal, 3 had received cortisone, 8 were alloxan-diabetic and 5 of these had also had cortisone, 7·5 mg. [*sic*] for 16 to 18 days.

The livers of cortisone-treated rabbits, normal or diabetic, were large and contained much glycogen. As the glycogen content rose the total phosphate and N fell, water and K remained relatively constant, and differences in Na and Cl were not related to glycogen. Apart from the blood sugar in diabetic rabbits, all serum values were normal. The correlation between increasing glycogen and falling total P was highly significant.

It is concluded that there is no uptake of phosphate by the liver during deposition of glycogen and that the fall in serum inorganic P during infusion of glucose is probably associated with peripheral utilisation of glucose.—D. Duncan.

PROTEINS AND PROTEIN DERIVATIVES

1986

NAGL, F. Zum Problem der Eiweissbilanz. [**The problem of protein balance.**] *Wien. klin. Wochenschr.*, 1955, **67,** 729–730. [Med. Abt., Städt. Krankenhaus, Vienna, Floridsdorf.]

The relation between serum protein and protein metabolism in the digestive tract is discussed.

1987

NAKAMURA, T. and INOKUCHI, T. **On the relation between N in foods and N in urine. (On the sense of protein requirement.)** *Wakayama Med. Rep.*, 1955, **2,** 75–87. [Lab. Osaka Nat. Sanatorium.]

From balance experiments with 3 patients with pulmonary tuberculosis an equation relating intake of N to output in urine has been calculated:

$$y = 16/(e^{-(x-90)/25} + 1) + 4,$$

where y is g. N excreted in urine and x is g. N ingested in food daily.

The experiments are discussed in relation to minimum and recommended allowances of protein, 40 and 160 g., respectively.—D. Harvey.

1988

PATRICK, R. M., BEAMER, K. C. and MOSCHETTE, D. S. **Metabolic studies with pre-adolescent girls. 3. Nitrogen retention.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1010–1015. [Dept. Home Econ., Louisiana Agric. Exp. Stat., Baton Rouge.]

For part 2 see Abst. 3747, Vol. 25.

N intake, excretion, absorption and retention were estimated for 6 healthy girls, 5 aged from 8 to 9 years and 1 aged 11 years, during a study lasting 56 days when the diet was controlled. Data were obtained for 8 periods; in 6 animal protein was excluded from the breakfast and in the other 2 fat-free milk was used. The diet was such that utilisation of carotene could be studied.

Samples of food, urine and faeces were collected and analysed for N.

Results for the 5 younger girls and the 11-year-old girl, respectively, were: mean daily total N intake 9·98 and 12 g.; protein intake 62·4 and 75 g.; protein intake per kg. bodyweight from 2·29 to 2·66 g. and 2·25 g.; N intake per sq. m. body surface 9·99 to 10·95 and 10·34 g.; total N excretion 82 and 82 per cent. of intake; urine N 7·28 and 9·79 g.; faecal N 0·77 and 0·56 g.; correlation coefficient between dry weight of faeces and faecal N, 0·807; absorption of N 92·3 and 95·3 per cent.; correlation between N intake and absorption per kg. bodyweight 0·965; N retention 1·93 and 1·64 g. or 19·4 and 13·7 per cent.; correlation between N intake and retention per kg. bodyweight 0·759. There was no significant effect of milk protein on mean retention of N.

G. F. Garton.

1989

HOLEMANS, K. and LAMBRECHTS, A. (with MARTIN, H.) **Nitrogen metabolism and fat absorption in malnutrition and in kwashiorkor.** *J. Nutrition*, 1955, **56,** 477–494. [Feshi, Belgian Congo.]

The results are tabulated for short-term balance experiments, 44 in all, on 26 children and 3 adults; 28 were on patients with kwashiorkor, 15 on others with chronic malnutrition and 1 was on a normal child. The findings for N are in 5 groups according to intake in mg. per kg. bodyweight in 24 hr. at intervals of 100 mg.; the numbers of subjects in these groups, irrespective of age or disease, and the means for intake and percentage retention were: 7, 169, 23; 14, 252, 49; 7, 346, 39; 7, 444, 60; and 9, 884, 54. On only 2 occasions was a balance negative. Two diets were used, one predominantly animal and the other vegetarian in respect of source of N; the averages for percentage N retained from these, 49 and 54, respectively, did not differ significantly. The evidence was that faeces contained about 30 mg. metabolic N per kg. daily.

Clinical steatorrhoea was thought not to be present, but from chemical analyses fat absorption was 80 per cent. on the average, which is below the usual, 95 per cent., in children.

The high N retention in these subjects is accounted for, probably, by relatively long subsistence on an intake of N insufficient to maintain the protein in their tissues at a normal level.

D. Harvey.

1990

FORSYTH, B. T., SHIPMAN, M. E. and PLOUGH, I. C. (with HACKLEY, B. and FRYAR, A.) **The relation of nitrogen retention to nitrogen intake in adults with post-traumatic malnutrition.** *J. Clin. Invest.*, 1955, **34,** 1653–1661. [Med. Div., Dept. Metabol., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington 12, D.C.]

The 13 subjects were severely injured soldiers. All except one were on liquid diet. As protein intake was varied energy intake and the carbohydrate : fat ratio in the diet were kept constant. Balance periods were sufficiently long to allow for re-equilibration of N metabolism after changes in intake. Faecal N was estimated in all studies. The losses of bodyweight, lean bodyweight and body fat after injury were estimated.

N retention was directly related to N intake. With N intakes ranging from 0·16 to 0·85 g. per kg. daily no loss of efficiency in N utilisation was evident at the higher intakes. Non-protein energy intake had little influence on N retention, and there was no relation between estimated loss of lean bodyweight and rate of N storage.—F. C. Aitken.

1991

SUBRAHMANYAN, V., NARAYANARAO, M., RAMARAO, G. and SWAMINATHAN, M. **The metabolism of nitrogen, calcium and phosphorus in human adults on a poor vegetarian diet containing ragi (*Eleusine coracana*).** *Brit. J. Nutrition*, 1955, **9,** 350–357. [Central Food Technol. Res. Inst., Mysore.]

Eight healthy men who were normally active were given a poor vegetarian diet based on ragi for 12 days; urine and faeces were collected during the last 5 days for estimation of total N, Ca and P. The composition of the diet was similar to that eaten by the poorer people in Mysore State. Food was analysed for total N, Ca and P and phytate P was estimated in food and faeces.

All the subjects maintained positive N balance; average daily N intake and retention were 10·6 and 1·1 g., respectively. Average daily excretion of N in faeces was 5·5 g.; apparent digestibility of the proteins from the diet was 50 per cent. Average daily intake and retention of Ca were 3·4 and 0·1 g., respectively; all the subjects maintained positive Ca balance. Average daily intake and retention of P were 2·3 and 0·2 g., respectively; all the subjects maintained positive P balance. Average daily intake of phytate P was 1·8 g., about 80 per cent. of the total P. Average daily excretion of phytate P in faeces was 0·3 g. About 85 per cent. of the phytate P ingested was hydrolysed during digestion.—G. F. Garton.

1993

MILLER, D. S. and BENDER, A. E. **The determination of the net utilization of proteins by a shortened method.** *Brit. J. Nutrition*, 1955, **9**, 382–388. [Crookes Laboratories, Ltd., Park Royal, London, N.W.10.]

Of 8 groups, each of 2 male and 2 female rats, one was given a protein-free diet and each of the others a different test-protein diet for 10 days, after which the intakes of food and N were calculated. The animals were killed and body water was estimated; the N content of the bodies was calculated from the water content by the formula $\log(4{\cdot}8 - y) = 0{\cdot}437 - 0{\cdot}0123x$, in which $y = \mathrm{N}/\mathrm{H_2O}$(in g.) $\times$ 100 and x = age in days. The net protein utilisation was calculated from the expression

$$\frac{\text{Body N of test group} - \text{Body N of no-protein group} + \text{N consumed by no-protein group}}{\text{N consumed by test group}}.$$

The net protein utilisation values of 26 proteins were calculated by this method and results showed good agreement with values reported in the literature. The biological value could be calculated from the net protein utilisation value by dividing by the digestibility. A method for estimating the limiting amino-acid in a given protein is described.

G. F. Garton.

1994

CALLOWAY, D. H. and SPECTOR, H. **Nitrogen utilization during caloric restriction. 1. The effect of dietary fat content. 2. The effect of variation in nitrogen intake. 3. The effect of preceding diet.** *J. Nutrition*, 1955, **56**, 533–544; 545–554; **57**, 73–88. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

1. Male rats were given a stock diet for 2 weeks; intake was controlled to maintain bodyweight at 300 g. Eight animals were then killed for carcase and liver analysis while 13 groups, each of 6 rats, received for 4 days diets with egg albumin or milk proteins containing either 30 or 5 per cent. fat at 3 levels of energy intake, 100, 50 or 25 per cent. of the maintenance energy requirement, which, under the conditions of this study, was found to be 46 Cal. daily. The rats were then killed and livers and carcases were analysed for N and fat.

Bodyweight loss was inversely proportional to energy intake and unaffected by the composition of the diet. All the groups which had a restricted energy intake were in negative N balance; egg albumin was slightly superior to milk proteins for promoting N equilibrium, but the fat content of the diet had no effect. Qualitative changes in composition were similar in both liver and carcase, but the changes were greater in the liver. Losses of N content were least in the groups given the full diet, greater and about equal in the groups given 50 and 25 per cent. of the maintenance energy requirement and greatest in one group which was fasted. The fat content was directly proportional to energy intake. There was no consistent relation between tissue losses and the fat content of the diet or the source of protein.

2. Male rats were standardised for 2 weeks in 3 series on a stock diet, a complete 18 per cent. casein diet, or stock diet for 2 days and 18 per cent. casein diet for 12 days. Five or 6 animals from each series were killed for tissue analysis. During the next 4 days groups of 5 or 6 rats from each series were given egg albumin diets which supplied 50 per cent. of the previous energy intake and graded amounts of N which ranged from 0 to 604 mg. per day. N utilisation was measured by N balance and by alteration in liver N content.

The loss of N was inversely proportional to the N intake; positive balance was not attained by any group. N utilisation diminished as N intake increased, from 52 to 61 per cent. at 70 to 80 mg. daily to 17 per cent. at 604 mg. There was no significant correlation between liver N loss and N balance.

3. A commercial stock diet, the same diet diluted with sucrose to reduce the protein content to that of an 18 per cent. casein diet, a casein diet with the same composition as the commercial diet, and a purified diet containing 18 per cent. casein were given to weanling rats for 2 weeks, followed by 12 days when energy intake was reduced by 50 per cent. by a diet of egg albumin. Groups of 8 rats were killed after standardisation and after 4, 8 and 12 days of restricted energy intake. In the second experiment, 6 groups each of 6 rats were given diets supplying 160, 275 or 455 mg. N as egg albumin or soya bean globulin; one group received a casein diet and another a protein-free diet for 2 weeks, followed by 4 days when energy intake was reduced by 50 per cent. and all groups received the egg albumin diet. In the third experiment the rats were given the commercial diet for 10 days; groups of 6 animals were then maintained for 2 weeks on diluted commercial diet, methionine-supplemented army ration, casein diet or egg albumin diet; the diets given during the following 4-day restriction period contained either egg albumin or a mixture of casein and lactalbumin. N balance and liver composition were estimated in all groups, and plasma protein and carcase composition were estimated in the prolonged restriction study.

During restricted energy intake bodyweight loss was significantly greater in animals given the unmodified commercial diet than those given any of the other diets. Also, during restriction, the negative N balance was directly proportional to the N intake during standardisation; although

this effect was greatest where egg albumin was the previous protein source, the variation due to level was smallest. N balance was not significantly affected by protein source during restriction. Liver N losses were correlated with the initial N content of that organ. No correlation was found between loss of liver N and N balance, though changes in carcase N agreed with balance data.—G. F. Garton.

1995

HORN, E. H. **Nutritional and hormonal influences upon reproductive maturation, organ weights and histochemistry of the immature male rat.** *Endocrinology*, 1955, **57**, 399–408. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

In all 179 rats 22 to 23 days old and weighing 42 to 49 g. were caged in fours. Controls received a diet with 18 per cent. casein, and the experimental diets contained 6 per cent. or no casein, the casein being replaced by starch. All except control rats were depleted on the protein-free diet for 30 days, and groups were then continued on this diet or repleted for 10, 20 or 30 days with 6 or 18 per cent. casein diets. Three groups repleted on 18 per cent. casein received thyroxine for the first 10, the second 10 or all 20 days of repletion. Organs and tissues were weighed and studied histologically at the end.

Depleted rats lost 25 per cent. of their body-weight in 30 days. Those continued on the protein free diet lost more weight and most of them died. Repletion with 6 per cent. casein for 30 days permitted the rats to regain their initial weight, and those given 18 per cent. casein put on another 103 g. and grew as rapidly as controls.

Testes lost weight during depletion, but no permanent harm was done and the lost growth was partly made up during repletion with the full diet. At the end of repletion spermatozoa were present in only 25 per cent. of the rats given 6 per cent. casein, and in 70 per cent. of those given 18 per cent. casein. In rats given thyroxine, 88 per cent. of the testes had spermatozoa after only 20 days. Lipid was present in the tubules after depletion.

Accessory sex organs only partly recovered lost weight on the full diet, and failed to recover it with only 6 per cent. protein. Lipid was deposited in liver and adrenals during depletion and only partly disappeared during recovery.—D. Duncan.

1996

VIJAYARAGHAVAN, P. K. **The haemopoietic activity of some food proteins.** *Indian J. Med. Res.*, 1955, **43**, 569–574. [Biochem. Lab., Univ. Madras.]

Eighteen groups, each of 6 young rats, were given different experimental diets for 4 days, after which anaemia was induced by a single intraperitoneal injection of phenylhydrazine hydrochloride. The composition of the basal diet was tapioca starch 65 to 75, butterfat 8, sugar 8 and salt mixture 4 parts; 6 proteins, namely, casein, egg albumin, meat protein, liver protein, wheat gluten and rice protein, were added to the diet at different levels in the different experiments; food and water were provided to appetite. Red blood cell counts and Hb estimations were made once in 4 days, and the time taken for the recovery of initial levels of these 2 criteria from the stage of severe anaemia was used for comparison of the efficiency for blood formation of the proteins studied.

At all levels studied animal proteins gave more rapid gains in red cells and Hb than vegetable proteins. The rate of regeneration of both red cells and Hb rose with the level of protein in the diet. The results showed that abrupt increases in Hb formation occurred at certain levels of intake when casein was used as the protein supplement; when the casein in the diet was raised from 5 to 15 per cent. the increase in Hb was raised from 56 to 75 per cent., and with an increase in casein from 30 to 35 per cent. the increase in Hb was raised from 90·6 to 97·1 per cent.; but when the protein intake was increased from 15 to 20 per cent. the increase in Hb formation was not significant. The level at which N equilibrium was produced by a protein did not provide an index of its efficiency in blood formation.—G. F. Garton.

1997

FINK, H. and HEROLD, E. Über die biologische Eiweissqualität von einzelligen Algen. Zugleich ein Beitrag zur alimentären Lebernekrose der Ratte und zur Therapie tropischen Eiweissmangelkrankheiten. [**Biological value of the protein of unicellular algae. A contribution on alimentary liver necrosis of the rat and the treatment of protein deficiency in the tropics.**] Über die Eweissqualität von einzelligen Algen und von jungen Grünblatt höherer Pflanzen. Zugleich ein Beitrag zur alimentären Lebernekrose der Ratte und zur Therapie tropischen Eiweissmangelkrankheiten. [**On the protein value of unicellular algae and of young green leaves of higher plants. A contribution on alimentary liver necrosis of the rat and the treatment of protein deficiency in the tropics.**] *Naturwissenschaften*, 1955, **42**, 516; 516–517. [Inst. Gärungswiss., Univ. Cologne.]

A more stringent test than before (see Abst. 4752, Vol. 24), in which 92 per cent. of the digestible protein of the diet of growing albino rats was supplied by dried unicellular algae (*Scenedesmus obliquus*), and the remaining 8 per cent. by brewer's yeast to supply B vitamins, confirmed the previous finding that algal protein was at least as good as milk protein for growth, and liver necrosis did not occur. This is considered to dispose of the idea

that animal protein is superior to vegetable. The algal diets were readily eaten. If the material can be made palatable for man, it should prove useful in the treatment of protein deficiency disorders of the tropics.

Commercial dried alfalfa meal was not so good as algal protein, but freshly gathered spinach from different regions, cooked in the usual way and given with its juice, was comparable to egg white and milk protein, and again there was no liver necrosis.—W. M. Deans.

1998

BAUMAN, A., ROTHSCHILD, M. A., YALOW, R. S. and BERSON, S. A. **Distribution and metabolism of I^{131} labeled human serum albumin in congestive heart failure with and without proteinuria.** *J. Clin. Invest.*, 1955, **34,** 1359–1368. [Radioisotope Serv., Veterans Admin. Hosp., Bronx, N.Y.]

Ten patients with heart disease, 5 of whom had proteinuria, and 10 without heart disease, 2 of whom had proteinuria, were given radio-active albumin free of rapidly degraded components. Solutions of albumin containing 85 to 115 μC of ^{131}I and 1 to 10 mg. protein were given intravenously. The uptake of ^{131}I by the thyroid was inhibited by 10 drops of Lugol's solution daily. Blood samples were taken 15 min. and 2, 6, 24, 30 and 48 hr. after the injection and daily for the next 25 to 35 days. Daily collections of urine were made and serum albumin was estimated weekly.

In 6 of the 7 patients with proteinuria, the amount of albumin degraded was less than in patients with no proteinuria. The amount of albumin synthesised was about the same as in subjects with no proteinuria. One patient with myxoedema but no proteinuria had the highest amount of exchangeable albumin, the largest extravascular fraction of total exchangeable albumin and the lowest rate of albumin synthesis. It is concluded that there is no obvious impairment of albumin synthesis or albumin stores in patients with congestive heart failure. The fall in serum albumin which may occur in heart failure may be related to increase in plasma volume.

B. W. Simpson.

1999

BLAHD, W. H., FIELDS, M. and GOLDMAN, R. **The turnover rate of serum albumin in the nephrotic syndrome as determined by I^{131}-labeled albumin.** *J. Lab. Clin. Med.*, 1955, **46,** 747–756. [Radioisotope Unit, Wadsworth Hosp., Veterans Admin. Centre, Los Angeles, Calif.]

In 3 out of 4 men with the nephrotic syndrome there was a high rate of turnover of serum albumin. Total exchangeable albumin was low, and so was circulating albumin. Albumin production was increased by a high protein intake and declined when protein intake was low and N balance negative.—D. Duncan.

2000

BENSON, J. A. (Jr.), KIM, K. S. and BOLLMAN, J. L. (with VAN HOOK, E.). **Extravascular diffusion of protein.** *Amer. J. Physiol.*, 1955, **182,** 217–220. [Sect. Biochem., Mayo Found., Rochester, Minn.]

Cannulae were inserted for collection of intestinal and hepatic lymph from rats and of hepatic, intestinal and hind-leg muscle lymph from rabbits. Human serum albumin labelled with ^{131}I was given by vein to the rabbits.

In intestinal lymph of rats output of protein was fairly constant, mean 122·3 $\pm$ 5·7 mg. per 100 g. bodyweight daily. The concentration varied inversely with rate of flow. In hepatic lymph the concentration of protein was about twice that in intestinal lymph and again was inversely related to rate of flow. In the rabbits the time required for the specific activity of plasma albumin to become identical with that for albumin from muscle, intestinal and hepatic lymph was about 25, 13½ and 4½ hr., respectively. Analysis of plasma and lymphs for total protein, albumin and globulin showed that it was in muscle lymph, in which exchange was slowest, that concentrations of albumin and globulin were least.—D. Harvey.

2001

HEGSTED, D. M., TRULSON, M. F., WHITE, H. S., WHITE, P. L., VINAS, E., ALVISTUR, E., DIAZ, C., VASQUEZ, J., LOO, A., ROCA, A., COLLAZOS CH., C. and RUIZ, A. **Lysine and methionine supplementation of all-vegetable diets for human adults.** *J. Nutrition*, 1955, **56,** 555–576. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

N intake and excretion were studied in young women, student dietitians at a hospital in Lima, Peru, during 3 experiments in which vegetable diets were eaten. The experiments were each divided into 3 periods, 3 to 7 days of depletion, when the vegetable diet low in total protein was eaten, and two 5-day periods when the subjects were given supplements of lysine, methionine or glycine. The N balance for each subject was estimated during the last 2 periods. The essential amino-acid content of the diets was estimated microbiologically; the basal diet, which supplied 25 g. protein daily, 48 per cent. from wheat products and 62 per cent. from cereals, contained all the essential amino-acids in quantities equalling or exceeding estimated minimum requirements.

Supplementation of the basal diet with lysine improved N retention and methionine plus lysine improved it further. It is emphasised that the

proteins of fruits and vegetables may be an important supplement to cereal proteins.

ROSE, W. C., EADES, C. H. (Jr.) and COON, M. J. **The amino acid requirements of man. 12. The leucine and isoleucine requirements.** *J. Biol. Chem.*, 1955, **216,** 225–234. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For part 11 see Abst. 695, Vol. 26.

N balance experiments with 5 normal young men showed that their minimum daily requirements of L-leucine were 0·50, 0·50, 0·70, 0·70 and 1·10 g. There was no correlation between minimum needs and bodyweight, body surface or creatinine output. Little, if any, D-leucine was utilised. The minimum daily requirements of DL-*iso*leucine of 4 young men were 1·40, 1·40, 1·40 and 1·30 g. As the D-isomer was not utilised, the minimum daily requirements of L-*iso*leucine were taken as half these values. The highest values, 1·10 g. L-leucine and 0·70 g. L-*iso*leucine, were tentatively designated as the minimum daily requirements of man, and twice these quantities were considered a safe daily intake.—A. Hepburn.

2003

ROSE, W. C. and WIXOM, R. L. **The amino acid requirements of man. 13. The sparing effect of cystine on the methionine requirement.** *J. Biol. Chem.*, 1955, **216,** 763–773. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

The daily methionine requirement of 3 healthy young men in the absence of dietary L-cystine was shown by N balance experiments to be 0·9, 1·0 and 0·8 g. With an intake of 0·81 g. cystine the methionine requirement was reduced to 0·1, 0·2 and 0·1 g. When methionine was completely excluded from the diet there was negative N balance and one man suffered from loss of appetite, nervous strain and vomiting. Another had similar symptoms when both cystine and methionine were omitted.—A. Hepburn.

2004

ROSE, W. C. and WIXOM, R. L. **The amino acid requirements of man. 14. The sparing effect of tyrosine on the phenylalanine requirement.** *J. Biol. Chem.*, 1955, **217,** 95–101. [Noyes Lab. Chem., Div. Biochem., Univ. Illinois, Urbana.]

See also Abst. 5243, Vol. 25.

Two young men were maintained in positive N balance by 0·8 and 1·0 g. L-phenylalanine, respectively. This could be reduced to 0·2 and 0·3 g. when 0·88 and 1·1 g. L-tyrosine was given also.

DALGLIESH, C. E. **Excretion of conjugated 2-amino-3-hydroxyacetophenone by man, and its significance in tryptophan metabolism.** *Biochem. J.*, 1955, **61,** 334–337. [Postgrad. Med. Sch., Ducane Rd., London, W.12.]

A substance with a strong blue fluorescence, found in a study of aromatic metabolites in the urine of patients with leucaemia or anaemia, was identified by chromatography and subsequent synthesis as 2-amino-3-hydroxyacetophenone. The possible derivation of the substance from tryptophan is discussed and theoretical evidence is presented to show that it could be formed by hydrolytic scission of the side-chain of hydroxykynurenine.—A. M. Copping.

2006

WOMACK, M. and MARSHALL, M. W. **Starches, sugars and related factors affecting liver fat and nitrogen balances in adult rats fed low levels of amino acids.** *J. Nutrition,* 1955, **57,** 193–202. [Human Nutrit. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington, D.C.]

In 7 experiments N balance was studied on male rats which had been maintained on a stock ration to appetite from weaning until 91 to 105 days old. In one experiment, 7 groups of rats were depleted of protein on N-free diets containing either sucrose, maize, dextrin, raw maize starch or one of 4 cooked starches, namely, maize, potato, rice and wheat starches, then given corresponding diets with an amino-acid mixture added; all the rats in the remaining 6 experiments, except 2 groups, were depleted of protein on N-free diets containing sucrose and then given different diets with added amino-acids; the 2 exceptional groups were depleted on N-free diets containing wheat starch or maize dextrin. After the N balance studies, which were made during the last 7 days of an 18-day protein-depletion period, and, after a week of adjustment, during 2 consecutive 7-day periods of amino-acid diets, the livers of the animals were removed for estimation of fat, protein and moisture.

Liver fat was less and negative N balances were smaller in the protein-depleted rats which received extra threonine, maize, rice or wheat starch or maize dextrin than in the rats given diets containing sucrose and low levels of amino-acids. The type of carbohydrate given during depletion had no effect on the results. Substitution of potato starch or glucose for sucrose reduced liver fat but did not improve N balance. The addition of nicotinic acid, methionine, cellu flour or sulphasuccidine or substitution of fructose for sucrose did not change the liver fat contents or N balances from those of the rats given sucrose. When the essential amino-acid intake of rats receiving

sucrose, glucose or fructose was doubled the liver fat content was reduced to normal or nearly normal.

GULLINO, P., WINITZ, M., BIRNBAUM, S. M., CORNFIELD, J., OTEY, M. C. and GREENSTEIN, J. P. **The toxicity of individual essential amino acids and their diastereomers in rats and the effect on blood sugar levels.** *Arch. Biochem. Biophys.*, 1955, **58,** 253–255. [Lab. Biochem., Nat. Cancer Inst., Bethesda, Md.]

The 10 amino-acids essential to the rat, L-*alloiso*-leucine and L-*allo*threonine were given separately to rats by intraperitoneal injection and their toxicity was studied. The D-isomers were less toxic than the L-isomers, except that both isomers of arginine were about the same. All the rats developed dyspnoea and hypothermia. Threonine, *allo*threonine and valine produced severe spastic muscular contractions; lysine and arginine produced coma and muscular relaxation. Degenerative lesions were not peculiar to any organ, but liver and kidneys were most damaged. All the rats had high blood sugar initially, but they died with conditions ranging from very high blood sugar after lysine to low blood sugar after valine, the leucines, phenylalanine, methionine or tryptophan.—A. Hepburn.

2008

GULLINO, P., WINITZ, M., BIRNBAUM, S. M., OTEY, M. C., CORNFIELD, J. and GREENSTEIN, J. P. **The toxicity of essential amino acid mixtures with special reference to the protective effect of L-arginine.** *Arch. Biochem. Biophys.*, 1955, **58,** 255–257. [Lab. Biochem., Nat. Cancer Inst., Bethesda, Md.]

The intraperitoneal administration to rats of a mixture of 9 of the essential amino-acids killed almost all of them, but mortality was reduced to 24 per cent. when the other amino-acid, arginine, was included in the mixture.—A. Hepburn.

2009

GREENSTEIN, J. P., WINITZ, M., GULLINO, P. and BIRNBAUM, S. M. **The prevention of ammonia toxicity by L-arginine and related compounds.** *Arch. Biochem. Biophys.*, 1955, **59,** 302–303. [Lab. Biochem., Nat. Cancer Inst., Nat. Inst. Health, Bethesda, Md.]

When L-arginine was administered to rats 60 to 90 min. before a usually lethal dose of ammonium acetate they all survived. Arginine given 4 hr. before the ammonium salt had negligible effect. D-Arginine and L-ornithine were protective, but less so than L-arginine. Acetyl-L-arginine, L-histidine, L-lysine and L-threonine were not protective.
A. Hepburn.

HARADA, M. and HORIGUCHI, G. **Bone and nutrition (secondary report): experimental studies on the effect of essential amino acid to bony tissue with special reference to the effect of tryptophan.** *Wakayama Med. Rep.*, 1955, **2,** 103–114. [Dept. Orthopaed. Surg., Wakayama Med. Coll.]

Rats weighing 50 to 70 g. were given a basal diet of 9 parts on dry basis of boiled potato and 1 part boiled sardine, or synthetic diets containing casein as the only protein (tryptophan-deficient) or with 0·1 or 0·5 per cent. added tryptophan.

The rats deprived of tryptophan showed in the bones thin epiphyseal plates with flattened undifferentiated cartilage cells and early calcification of hypertrophic cartilage cells, not seen in rats on a restricted intake of basal diet. Those given excess tryptophan showed delayed calcification of hypertrophic cells and also dense, thick spicules in the cartilage matrix.—D. Duncan.

2011

KOTAKE, Y., SHIBATA, Y., INOUYE, K. and HOTTA, Y. **On the excretion of xanthurenic acid caused by administration of tryptophan to albino rats with the hypophysis or suprarenal glands extirpated.** *Wakayama Med. Rep.*, 1955, **2,** 133–137. [Dept. Biochem., Wakayama Med. Coll.]

In rats with adrenals removed, tryptophan given by mouth decreased the output of xanthurenic acid in urine, but did not affect anthranilic acid or kynurenine. In rats with the pituitary removed, tryptophan decreased the output of all 3 substances. After either operation spots corresponding to N^1-formylkynurenine and 3-hydroxykynurenine were found on chromatograms of urine; they were not found in normal urine.

SHOSH, I. Narusheniya funktzii organov pri nedostatke metionina i lizina v pitanii. [**Disturbance in the function of organs caused by deficiency of methionine and lysine in the food.**] *Vop. Pitan.*, 1955, **14,** No. 5, 16–20. [Inst. Patol., Budapest Med. Univ.]

The methionine-free diet given to 215 rats contained, per cent., gelatine 15, dried yeast 3, fat 10, cod liver oil 1, salts 4, starch 66 and tryptophan 1. Another 75 rats had similar diets, but with $\frac{2}{3}$, $\frac{1}{3}$ or $\frac{1}{2}$ as much methionine as was provided by the control diets. The lysine-deficient diet given to 38 rats contained, per cent., wheat gliadin 18, fat 10, cod liver oil 1, starch 67, salt mixture 4 and vitamins. The control diets were a stock ration and a synthetic ration containing 16 per cent. casein and 3 per cent. dried yeast, which gave good growth and no sign of disturbance.

Rats on the experimental rations failed to thrive. Pathological changes in the organs were examined. The low methionine intake produced portal, perilobular fatty infiltration in the liver and sometimes necrosis and cirrhosis. Fat infiltration was also present in lysine deficiency, but there was no cirrhosis.

The pancreas in methionine deficiency soon showed vacuolisation and damaged cells and then cystic fibrosis. This did not occur in lysine deficiency. The lungs in methionine deficiency often showed bronchiectasis and emphysema, and the elastic layer of the bronchi was found to be destroyed.

The curve of muscular contraction showed a loss of amplitude and slow reaction in deficiencies of either lysine or methionine, but no change was found histologically. The kidney in either deficiency showed hyperaemia, often degeneration and even necrosis. Changes in the ductless glands were found.—D. Duncan.

McCLURE, F. J. and FOLK, J. E. **Lysine and cariogenicity of two experimental rat diets.** *Science*, 1955, **122,** 557–558. [Nat. Inst. Dent. Res., Nat. Inst. Health, Bethesda, Md.]

Work with diets containing skimmed milk powders (see Absts. 2112, Vol. 23 ; 958, Vol. 24 and 5477, Vol. 25) was continued by more intensive study of the role of lysine in the diets described in the first 2 papers. Paired rats were fed for 60 or 90 days. With the first diet DL-lysine, 2·5 g. per 100 g., greatly reduced the incidence and severity of caries. In the rest of the work, which was with the diet described in the second paper, additions of L-lysine at rates between 0·25 and 2·5 per cent. of the diet were studied ; on the average the incidence was reduced by 59 per cent. and the severity score by 83 per cent. The effects were not reproduced if other acids, L-arginine or L-histidine, or the compounds with similar structure, D-lysine, ornithine or cadaverine, were added instead of L-lysine.

The studies are being continued.—D. Harvey.

MELVILLE, D. B., OTKEN, C. C. and KOVALENKO, V. **On the origin of animal ergothioneine.** *J. Biol. Chem.*, 1955, **216,** 325–331. [Dept. Biochem., Cornell Univ. Med. Coll., New York.]

In an attempt to duplicate the experiment of Heath *et al.* (Abst. 738, Vol. 24) the subject was an 8-week-old boar pig, fed since weaning on a diet of cracked maize 200, bran 100, middlings 100, meat scraps 50, bonemeal 50, oilmeal 50, NaCl 5, charcoal 5 and dried skimmed milk 25 parts. Initially the blood contained 14·5 mg. ergothioneine per 100 ml. The pig was given in the feed methionine labelled with 1 mC. ^{35}S, and 3 weeks later was anaesthetised and bled.

No radio-activity could be detected in ergothioneine obtained in crystalline form from the blood, or in the ergothioneine-containing fractions of tissue from the seminal vesicles.

In a similar experiment with a rat, no ^{35}S was detected in blood ergothioneine 17 days after 1 mC. ^{35}S had been given as methionine.

Six rats received for 3 to 5 weeks a diet containing 20 per cent. casein as the only protein, after which ergothioneine was not detectable in blood. Pairs of rats were then given 0·01, 0·05 and 0·001 per cent. pure ergothioneine in the diet. Blood ergothioneine rose to 4 mg. per 100 ml. in 2 weeks and 8 mg. per 100 ml. in 4 weeks in the rats given 0·01 per cent., and to 1 mg. per 100 ml. in 8 weeks in those on the lowest intake.

In 10 rats given a diet in which casein was replaced by zein, lysine, histidine, tryptophan, threonine, methionine and valine no ergothioneine was found in blood until ergothioneine was added to the diet. A diet containing 20 per cent. of this mixture of zein and amino-acids and 45 per cent. maize produced levels of about 1 mg. ergothioneine per 100 ml. blood after 12 weeks. An aqueous acetone extract of maize also permitted rats to maintain blood ergothioneine levels.—D. Duncan.

RICCERI, G. Sul problema della biosintesi delle purine. 1. L'influenza delle diete prive di alcuni aminoacidi sul metabolismo purinico del ratto. [**The biosynthesis of purines. 1. Influence of diets without certain amino-acids on the purine metabolism of the rat.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 283–286. [Ist. Fisiol., Univ. Catania.]

Allantoin is the ultimate product of purine metabolism in the rat. To test whether arginine and histidine are essential for synthesis of purines, 3 experiments were made, each with 2 male rats from 4 to 6 months old, maintained for from 40 to 80 days on a protein-free diet, which led to rapid decrease in the amount of allantoin in the urine. Different L-amino-acids, including arginine and histidine, were then added cumulatively, but the amount of allantoin in the urine continued to decrease until all the essential amino-acids were being given, when it rose sharply to the normal value.—E. M. Hume.

DINO, S. and VITTORIO, C. Dei composti indossilici. [**Indoxyl compounds.**] *Zootec. Vet.*, 1955, **10,** 408–418. [Ist. Anat., Univ. Cattol. Sacro Cuore, Milan.] English summary.

There is a review of the literature on the physiology of indoxyl compounds.

Indican was estimated in the blood of 5 heifers and 7 mares after 10 days on a ration of lucerne and oat hay. The values for heifers were 1·0 to 4·2 mg. per 100 ml. plasma, mean 2·2, and for mares 2·1 to 4·1, mean 3·3.

Indican values in the urine of mares fed on pasture with 85 per cent. ladino clover were from 0·14 to 0·29 per cent., on pasture with 60 per cent. lucerne 0·29 to 0·35 and on lucerne and oat hay 0·08 to 0·17. Corresponding values for heifers were 0·08 to 0·21, 0·28 to 0·33 and 0·16 to 0·22 per cent.

Rabbits given indole by mouth in increasing quantities up to 0·8 g. daily showed no ill effect on the thyroid or parathyroids.

In chickens no indican was found in the urine, but it was present in small quantities in the intestine and there was a mean value of 1·5 mg. per 100 ml. in the blood.—D. Duncan.

FATS AND OTHER LIPIDS

2019

GUILBERT, P., BAKER, D. and BARNESS, L. A. **Fat retention in infants fed breast milk and humanized cow's milk.** *J. Pediat.*, 1955, **47,** 683–689. [Dept. Paediat., Hosp. Univ. Pennsylvania, Philadelphia.]

Five healthy male babies aged from 12 to 45 days were fed for alternate periods of average length 15 days on modified cow's milk mixtures and breast milk. The cow's milk was sterilised by heat and modified to an unstated composition by the addition of water, lactose and vegetable fat. The breast milk was frozen unsterilised pooled milk modified in the same way so that each infant received feeds of the same energy and protein content. The babies were fed every 4 hr. to appetite and were given vitamin supplements.

Fat balances over 3-day periods indicated that the percentage of fat retained, ranging from 85 to 98, was the same for both types of feeding. There was a small increase in fat retention as the infants became older.

The stool *p*H was the same on both types of diet and the stool flora was also similar, except that *L. bifidus* var. *pennsylvanicus* was present only during or just after a period of breast milk feeding.

JOCHIMS, J. and DOERKS, G. Zur Methodik der Chylomikrographie und zur Physiologie der Fettresorption beim Säugling. [**Technique of chylomicrography and the physiology of fat absorption in the infant.**] *Ztschr. Kinderheilk.*, 1955, **77,** 278–292. [Kinderklin., Städt. Krankenhaus Süd, Lübeck.]

The technique of chylomicron counts is discussed. Fasting counts from 66 estimations on infants 5 to 14 months old ranged from 1750 to 22,500 chylomicrons per c.mm. serum, but the latter value is probably too high. Curves were made for 4 hr. after a milk meal in 66 infants ; the peak was almost always much later than the usual time of 2 hr. reported by Frazer and Stewart (*J. Physiol.*, 1939, **95,** 23P) in adults, and in 35 tests the count was still rising at 4 hr. In individual infants the curves on successive days in similar conditions were sometimes, but not always, identical. It is concluded that there are physiological variations.

In 30 studies on 7 infants the chylomicrograph was studied in relation to emptying of the stomach as shown by X-ray. The more food there was in the stomach 3 to 4 hr. after the meal the less was the fat absorption as shown by the chylomicrograph. When several children after identical meals had different chylomicron counts, these reflected the size of the stomach at that time.—D. Duncan.

2021

REDETZKI, H. and GRONOW, R. T. Untersuchungen über die Fettresorption und die alimentäre Lipämie nach Fettbelastung. [**Absorption of fat and blood fat after administration of fat.**] *Klin. Wochenschr.*, 1955, **33,** 701–705.

[1. Med. Abt., Allg. Krankenhaus St. Georg, Hamburg.]

Total fat, total cholesterol, lipoid phosphorus and turbidity of serum were estimated in 36 men while fasting from normal diets, at intervals after ingestion of 1 g. olive oil per kg. bodyweight. Half the subjects attained their maximum values for serum lipids after 195 min. or more. Sixteen showed the maximum after 135 min. and 2 after 90 min. A second test 4 days later confirmed the results.

Commercial lipase preparations were given to 22 subjects 20 min. before the oil. Some from pancreas hastened absorption of fat, but other preparations had little or no effect. Bile preparations hastened absorption of fat in some and inhibited it in others. The turbidity of the serum was related to the total lipid and neutral fat contents.

THOMASSON, H. J. **The biological value of oils and fats. 1. Growth and food intake on feeding with natural oils and fats.**

THOMASSON, H. J. and BOLDINGH, J. **2. The growth-retarding substance in rapeseed oil.**

THOMASSON, H. J. **3. The longevity of rats fed rapeseed oil- or butterfat-containing diets.** *J. Nutrition*, 1955, **56,** 455–468; 469–475; **57,** 17–27. [Unilever Res. Lab., Zwijndrecht, Netherlands.]

1. The growth-promoting effect of 20 different oils and fats was investigated. For each fat, 8 groups of 8 to 12 male 12-day-old rats were fed for 6 weeks on diets in which the test fat was incorporated at 10, 20, 30, 40, 50, 60 and 73 per cent. of the energy value. The reference diet contained summer butterfat as 20 per cent. of its energy value. Food and water were provided to appetite. The fats were lard, olive oil, cottonseed oil, beef fat, shea butter [*Butyrospermum parkii*], maize oil, soya bean oil, groundnut oil, palm fat, sunflower seed oil, poppyseed oil, coconut fat, sesame oil, owalanut oil, whale oil, herring oil, rapeseed oil, kapok seed oil and winter butterfat.

With summer butterfat the rate of growth remained almost unchanged as the fat content of the diet was increased; with the other fats, except lard, there was a decrease of growth rate with increasing dietary fat. The increase in weight per food calorie was independent of the type of fat or the level at which it was administered, except for shea butter and palm oil.

It is suggested, in opposition to earlier claims that butterfat contains a growth-promoting substance, that many other fats contain growth-retarding substances.

2. In experiments similar to those described above the effect on growth of nasturtium seed oil, containing 80 to 90 per cent. of erucic acid, was compared with that of rapeseed oil, containing 40 to 57 per cent. erucic acid. The effect on growth of mixtures containing erucic acid or trierucin was compared with the effect of rapeseed oil. The results indicated that the unfavourable effect of rapeseed oil on growth must be ascribed to its erucic acid.

3. In similar experiments it was shown that male rats fed to appetite on a diet containing rapeseed oil as 50 per cent. of its energy value lived 20 to 25 per cent. longer than animals given a similar diet containing butterfat, though both growth rate and daily food intake of the animals fed on rapeseed oil were lower than those of the rats given butterfat. Rats in both groups showed pathological changes, especially necrotic and inflamed lesions of the soles of the hind feet and kidney degeneration, which were more pronounced after butterfat; slight liver degeneration was found only after rapeseed oil.—G. A. Garton.

HOPKINS, C. Y., MURRAY, T. K. and CAMPBELL, J. A. **Optimum ratio of saturated to mono-unsaturated fatty acids in rat diets.** *Canad. J. Biochem. Physiol.*, 1955, **33,** 1047–1054. [Div. Pure Chem., Nat. Res. Counc., Ottawa.]

Groups of male or female weanling and immature rats were fed for 9 weeks on a diet composed of 80 parts fox chow of low fat content and 20 parts of different fat mixtures. The fat mixtures all contained linoleic acid as about 10 per cent. of the total fatty acids and the ratio of saturated to mono-unsaturated fatty acids was varied from 3·5 : 1 to 1 : 8 by including differing proportions of maize oil, coconut oil and olive oil.

Both weanling and immature male rats showed significant differences in weight gain on the different diets; the greatest gain was made on the diet with a ratio of saturated to mono-unsaturated fatty acids of 1 : 2; this ratio was similar to that in normal rat depot fat. Female rats did not show significant differences in weight gain on the different diets.—G. A. Garton.

MAYER, J. and ZIGHERA, C. Y. **Fat metabolism in various forms of experimental obesity. 6. Instantaneous lipogenesis in hypothalamic obese mice.** *Experientia*, 1955, **11**, 358–359. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

For preceding paper see Abst. 824, Vol. 26.

Groups of fasted and non-fasted mice, rendered obese by surgical lesions in the hypothalamus, were injected with acetate-carboxyl-^{14}C; suitable unoperated animals were similarly treated. The mice were killed after 30 min. and liver and carcase fatty acids were isolated for estimation of their radio-activity.

The non-fasted obese mice incorporated about 4 times as much acetate into fatty acid as did the controls; fat formation was 3 times as great in the carcase and more than 7 times in liver. In the fasted mice total incorporation of ^{14}C into liver and carcase lipids was similar in obese and non-obese animals.—G. A. Garton.

ROSSI, C. S. Meccanismo dell'azione lipotropa della colina confrontato con quello della betaina. [**Mechanism of lipotropic action of choline compared with that of betaine.**] *Arch. Sci. biol., Bologna*, 1955, **39**, 450–455. [Ist. Chim. Biol., Univ. Padua.]

Of 4 groups of 4 guineapigs the first were untreated controls and the animals of the other 3 received carbon tetrachloride intramuscularly daily for 5 days; the third and fourth groups had at the same time 7 mg. per 100 g. bodyweight daily of betaine or choline, also intramuscularly. The total lipid content of the liver was then estimated, and the values in mg. per g. dry tissue were examined statistically.

In the guineapigs given CCl_4 alone the liver lipids increased by 100 per cent. over the control values, a statistically significant difference. The increases with CCl_4, plus betaine or choline, 29 and 21 per cent. [there is a discrepancy between the means as given in the table and these values taken from the following page], were not statistically significant and therefore the difference between the effects of betaine and choline was not significant.

The guineapig has no choline oxidase (Bernheim and Bernheim, *Amer. J. Physiol.*, 1933, **104**, 438), so the effect of choline is thought to be direct and that of betaine is probably also direct.

VENTURI, V. M. Contributo alla conoscenza dell'azione di fattori lipotropi sulla steatosi epatica in ipossia sperimentale. [**The action of lipotropic substances on fatty liver in experimental hypoxia.**] *Arch. internat. Pharmacodyn.*, 1955, **103**, 238–241. [Ist. Farmacol., Univ. Pavia.] English summary.

Groups of mice, 301 animals in all, were exposed to hypoxia after some had received intraperitoneal injections of methionine or choline.

Both lipotropic substances, especially choline, reduced the severity of histologically visible fat deposition in the liver, but there was no effect on time of survival.—D. Duncan.

KARTHA, A. R. S. **The glyceride structure of natural fats. 3. Factors governing the content of fully saturated glycerides.** *J. Amer. Oil Chem. Soc.*, 1954, **31**, 85–88. [Maharaja's Coll., Ernakulam, India.]

The hypothesis that fully saturated triglycerides cannot be present in natural fats in excess of the quantity which can exist in the fluid state *in vivo* is discussed in relation to the known glyceride structure of many fats. It is suggested that the enzyme systems involved in the synthesis of glycerides are not able to produce solid-phase molecules, since these cannot be adsorbed as a film on the enzyme surface.—G. A. Garton.

DEUEL, H. J. (Jr.), MARTIN, C. R. and ALFIN-SLATER, R. B. **The effect of fat level of the diet on general nutrition. 16. A comparison of linoleate and linolenate in satisfying the essential fatty acid requirement for pregnancy and lactation.** *J. Nutrition*, 1955, **57**, 297–302. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

With procedures similar to those described earlier (Deuel *et al.*, Abst. 5287, Vol. 25), the

relative effects of linoleate and linolenate separately and in combination were investigated in experiments on reproductive performance in rats.

Linolenate was found to be less effective than linoleate at all intakes studied. In every group, except controls given a fat-free, unsupplemented diet, all the rats produced young and almost the same number of young, but when reproductive capacity was judged by percentage surviving at 3 days, mortality was much greater in the animals given linolenate except at the highest intake studied, 100 mg. daily.

When mixtures of linoleate and linolenate were given, the effect of linolenate was equal to, if not greater than, that of an equal amount of linoleate.

BLOMSTRAND, R. **Transport form of decanoic acid-1-^{14}C in the lymph during intestinal absorption in the rat.** *Acta. physiol. scand.*, 1955, **34,** 67–70. [Dept. Physiol. Chem., Univ. Lund.]

Decanoic acid-1-^{14}C was administered, in solution in olive oil, to adult male rats with thoracic duct cannulae. Lymph was collected for 24 hr. and extracted with ethanol and ether to yield the lipids, which were fractionated by chromatography. Each fraction was assayed for ^{14}C activity. Fatty acids were also extracted from the intestinal tract at the end of 24 hr. and pooled with those isolated from faeces; ^{14}C activity gave a measure of the extent of absorption of the labelled acid.

The decanoic acid was almost quantitatively absorbed in 24 hr. and 3 to 16 per cent. of the absorbed ^{14}C activity was found in lymph lipids; most of this activity was located in triglycerides and the rest in phospholipins. No significant amount of the labelled acid appeared free in the lymph.—G. A. Garton.

2034

BORGSTRÖM, B. **Transport form of ^{14}C-decanoic acid in porta and inferior vena cava during absorption in the rat.** *Acta physiol. scand.*, 1955, **34,** 71–74. [Dept. Physiol. Chem., Univ. Lund.]

Two fasting adult rats were given 1 ml. olive oil containing 28·1 per cent. free decanoic acid labelled with ^{14}C; 1·5 hr. later they were anaesthetised and blood was collected simultaneously from the inferior vena cava and the portal vein. Lipids were extracted from the blood samples and separated by chromatography on silicic acid columns, after which ^{14}C was estimated. Similar experiments were made on 4 other rats, each of which received olive oil containing 10 per cent. of labelled decanoic acid; blood samples were taken 1·5 to 3·0 hr. later.

The largest part of lipid ^{14}C activity recovered from both portal and vena cava blood was in the form of free decanoic acid, showing that free acid absorbed into the portal blood, 4 to 5 mg. per cent., was not quickly removed from the circulation. These findings contrast with those of other workers for the long-chain acids C_{15} to C_{18}, which are transported almost quantitatively via the lymphatic pathway whether they are given as esters or as free acids.—G. A. Garton.

SHAPIRO, S. L. and FREEDMAN, L. **Effect of essential unsaturated fatty acids and methionine on hypercholesteremia.** *Amer. J. Physiol.*, 1955, **181,** 441–445. [Res. Labs., U.S. Vitamin Corp., Yonkers, N.Y.]

Groups of 16 rats were fed on sulphur-deficient diets containing 3 per cent. cholesterol with 5 per cent. hydrogenated fat and 0·6 per cent. methionine; 2·5 per cent. hydrogenated fat, 2·5 per cent. safflower oil and 0·6 per cent. methionine; 5 per cent. safflower oil and 0·6 per cent. methionine; 5 per cent. safflower oil; or 5 per cent. hydrogenated fat. Serum cholesterol was estimated after the diets had been given for 22 days, and plasma cholesterol after 40 days.

The high blood cholesterol found in rats given cholesterol in an S-deficient ration was almost prevented by the inclusion of safflower oil, which contained 80 per cent. linoleic acid, and methionine in the diet. Under the same conditions, replacement of the unsaturated oil by hydrogenated fat did not effectively prevent the development of high blood cholesterol.

The results are discussed with reference to the role of unsaturated fatty acids in the prophylaxis of atherosclerosis.—G. A. Garton.

SIPERSTEIN, M. D. and MURRAY, A. W. **Cholesterol metabolism in man.** *J. Clin. Invest.*, 1955, **34,** 1449–1453. [Lab. Chem. Pharmacol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Cholesterol-4-^{14}C was injected intravenously into a patient whose common bile duct had been cannulated during cholecystectomy. After the injection bile was collected for 50 hr. and during this time, and subsequently, faeces and urine were collected for ^{14}C assay; a sample of expired air was taken 29 hr. after the injection.

By all routes of elimination 39·6 per cent. of the ^{14}C administered was excreted within 50 hr.; more than 98 per cent. of the activity was in the bile, 1·3 per cent. in the faeces and 0·2 per cent. in the urine; no $^{14}CO_2$ was found in the expired air. The main excretory product of cholesterol in bile was identified as glycocholic acid.—G. A. Garton.

GOULD, R. G., LEROY, G. V., OKITA, G. T., KABARA, J. J., KEEGAN, P. and BERGENSTAL, D. M. **The use of C^{14}-labeled acetate to study cholesterol metabolism in man.** *J. Lab. Clin. Med.*, 1955, **46**, 372–384. [Univ. California Los Alamos Sci. Lab., N. Mex.]

Acetate-1-^{14}C providing 100 or 200 μC. was given either by mouth or intravenously once or oftener to each of 34 patients in a cancer research hospital. With either route of administration, the peak of the specific activity time curve for the free cholesterol of plasma was reached 2 to 4 hr. after the acetate was given. The rate of interchange of free cholesterol between liver and plasma in each direction was estimated to be at least 0·87 g. per hr. Equilibrium between cholesterol-^{14}C in plasma and red cells was reached in 8 to 12 hr., and that between free and esterified cholesterol in plasma took 24 to 48 hr. to become established ; in some subjects the specific radio-activity of plasma cholesterol was followed for 7 weeks after the dose of ^{14}C-acetate.

The fraction of the amount of labelled acetate which was used to form cholesterol was 1·04 per cent. in normal subjects, 0·23 per cent. in patients with myxoedema, 4·0 per cent. in patients with cancer and 4·75 in subjects treated with cortisone, which shows that the metabolic state of the subject conditions the rate of formation of cholesterol in the liver.—G. A. Garton.

LIN, T. M., KARVINEN, E. and IVY, A. C. **Relation of dietary fat to the absorption and elimination of exogenous and endogenous cholesterol.** *Amer. J. Physiol.*, 1955, **183**, 86–90. [Dept. Clin. Sci., Univ. Illinois Coll. Med., Chicago.]

Cholesterol balance was studied on groups of individually-caged rats fed for 6 days on a fat-free diet to which was added 50 mg. cholesterol daily and 7 per cent. maize oil, beef tallow, triolein, trielaidin, tripalmitin, oleic acid or palmitic acid. Faeces were collected for analysis during the fifth and sixth days of the experiment.

Oleic acid improved intestinal absorption of dietary cholesterol more than did tallow, maize oil and (unexpectedly) triolein ; the last had no effect. Trielaidin, tripalmitin and palmitic acid partly inhibited absorption of cholesterol.

2039

BYERS, S. O. and FRIEDMAN, M. (with OMOTO, C.) **Observations concerning the production and excretion of cholesterol in mammals. 15. Role of the pancreas in intestinal absorption of cholesterol.** *Amer. J. Physiol.*, 1955, **182**, 69–72. [Harold Brunn Inst. Cardiovascular Res., Mount Zion Hosp., San Francisco, Calif.]

For part 14 see Abst. 5304, Vol. 25.

Cholesterol absorption was found to be impaired in male adult rats given cholesterol in olive oil 2 days after ligation of the pancreatic ducts. Little change in absorption was noted 7 and 28 days after ligation. Total removal of the pancreas resulted in reduction of cholesterol absorption by about 50 and 35 per cent. after 7 and 28 days, respectively. After an 18-hr. fast, rats given cholesterol in olive oil with pancreatic extract showed no increase in cholesterol absorption compared with controls. Total lipid absorption was found in all experiments to be roughly parallel to cholesterol absorption. It is suggested that absorption of cholesterol is to some extent independent of pancreatic secretion.—A. K. Lough.

2040

PIHL, A. **The effect of dietary fat on the intestinal cholesterol absorption and on the cholesterol metabolism in the liver of rats. Cholesterol studies 3. On the mode of action of fatty acids in cholesterol absorption. Cholesterol studies 4. The effect of bile acids on cholesterol absorption, deposition and synthesis in the rat. Cholesterol studies 5.** *Acta physiol. scand.*, 1955, **34**, 183–196 ; 197–205 ; 207–217. [Nutrit. Res. Inst., Univ. Oslo.]

3. Groups of adult rats were used in balance studies in which cholesterol was 0·25, 0·5 or 1·0 per cent. of diets containing 5, 10 or 15 per cent. arachis oil or none. Cholesterol was absorbed when diets containing no fat were given, though dietary fat increased the absorption of the sterol when the ratio of fat to cholesterol in the diet was at least 15 : 1.

Considerable deposits of cholesterol esters were found in the livers of animals fed for 7 weeks on a fat-free diet containing cholesterol. Further studies were designed in which equal amounts of cholesterol were absorbed by groups of rats given a fat-free diet or one containing 15 per cent. fat for 7 weeks. About twice as much cholesterol was found in the livers of rats given fat as in the livers of those given none.

The effect of dietary fat on cholesterol metabolism in liver was studied in rats given for 34 days a stock diet containing 1 per cent. cholesterol and then for 8 days a cholesterol-free diet containing either 2 or 30 per cent. arachis oil. The cholesterol content of the livers of the rats given 30 per cent. arachis oil was less than that in the group given 2 per cent. oil. Liver slices from rats given the high-fat diet showed the greater capacity to convert ^{14}C-labelled acetate into cholesterol.

4. Balance experiments were made for 7 days on groups of young rats given diets containing 1 per cent. cholesterol with 9 per cent. oleic or stearic acid or diets containing cholesterol oleate or stearate corresponding to 1 per cent. cholesterol; in one experiment cholesterol acetate corresponding to 0·25 per cent. free cholesterol was administered.

Absorption of cholesterol increased in animals given oleic acid, but stearic acid had no effect. Cholesterol oleate and stearate were not absorbed better than the free sterol. The acetate was readily absorbed.

Esterified cholesterol was found in faeces when stearic acid was given with free cholesterol, but not when oleic acid was given; the addition of bile acids to the diets did not affect the result. The cholesterol esters, including the acetate, were hydrolysed in the intestine. When free fatty acids, especially oleic acid, were given in the diet the faecal excretion of phospholipins was increased.

5. In similar balance experiments the intestinal absorption and liver deposition of cholesterol was studied when cholic, deoxycholic or dehydrocholic acid was added as 0·5 per cent. of the diet.

The addition of bile acid to a fat-free diet did not increase the absorption of cholesterol. No conclusive evidence was obtained of an effect of bile acids on the absorption of cholesterol from diets containing fat or fatty acids. Deposition of cholesterol in liver was increased by the presence of bile acid in the diet; these increases were accompanied by high serum cholesterol. As judged by the incorporation of ^{14}C-acetate into cholesterol in liver slices, cholic acid did not promote formation of cholesterol in the liver. It is concluded that bile acids probably interfere with the catabolism of cholesterol in the liver.

G. A. Garton.

2041

KARVINEN, E., LIN, T. M. and IVY, A. C. **Effect of mineral oil in intestinal absorption of cholesterol in the rat.** *Amer. J. Physiol.*, 1955, **181,** 439–440. [Dept. Clin. Sci., Univ. Illinois Coll. Med., Chicago.]

Groups of rats were fed for 6 days on a basal cholesterol-free diet to which was added 40 mg. cholesterol daily or 6 per cent. light mineral oil or both. During the last 2 days of the study faeces were collected and analysed for cholesterol.

The addition of light mineral oil alone to the diet was accompanied by an increase of 39 per cent. in excretion of endogenous cholesterol, and when cholesterol also was given, the total faecal cholesterol was increased by 30 per cent. It is considered that most of the increased excretion is due to the solubility of cholesterol in mineral oil.

G. A. Garton.

DASKALAKIS, E. G. and CHAIKOFF, I. L. **The significance of esterification in the absorption of cholesterol from the intestine.** *Arch. Biochem. Biophys.*, 1955, **58,** 373–380. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Doses of ^{14}C-cholesterol ranging between 1 and 48 mg. were given by stomach tube to rats with thoracic duct cannulae; lymph was collected for 24 hr. and analysed for free and total cholesterol and total ^{14}C content.

Although the amount of cholesterol recovered from the lymph increased with the amount of cholesterol given, the percentage of cholesterol absorbed decreased. Whatever the amount of cholesterol given, about 70 per cent. appeared in the lymph in esterified form.

In similar experiments other sterols, 3 mg. of each, were given with 3 mg. cholesterol and the effect on absorption of cholesterol was studied. Dihydrocholesterol and ergosterol inhibited absorption of cholesterol to the extent of 80 and 50 per cent., respectively, though they did not affect the percentage of sterol found in esterified form in the plasma. The following compounds had no effect on either absorption of cholesterol or extent of its esterification: *allo*cholesterol, cholestenone, dehydro*iso*androsterone, 7-dehydrocholesterol, epicholesterol, brassicasterol and stigmasterol.

RIDDELL, C. and COOK, R. P. **Cholesterol metabolism. 4. The neutral fraction of the faecal lipid of rats fed diets with low and high cholesterol contents.**

EDWARDS, D. C. and COOK, R. P. **5. The excretion of acids after cholesterol ingestion in rats.**

COOK, R. P., EDWARDS, D. C., RIDDELL, C. and THOMSON, R. O. **6. The fate of ingested cholesterol in the intact rat.** *Biochem. J.*, 1955, **61,** 657–671; 671–676; 676–681. [Dept. Biochem., Queen's Coll., Dundee (Univ. St. Andrews).]

For part 3 see Abst. 2300, Vol. 21.

4. Male rats were fed on diets with or without olive oil, and with or without added cholesterol. Faecal unsaponifiable matter, which consisted largely of digitonin-precipitable sterols, was excreted in greatest amount in proportion to sterol ingested by the rats on low-fat diet. Fractionation of faecal unsaponifiable matter from rats on the low-fat diet showed that when supplements of cholesterol were given much of the increase in unsaponifiable matter could be accounted for by cholesterol and saturated sterols. The fraction of unsaponifiable matter not precipitable with digitonin apparently includes hydrocarbons, ketones and 3α-stanols. The method of fractionation, which included adsorption chromatography on alumina,

revealed a complex mixture of sterols, sterol metabolites and, possibly, steroid metabolites.

5. The faecal excretion of ether-extractable acids and esterified sterol was higher in rats fed on a diet containing added cholesterol. "Solid" and "liquid" acids separated from the ether-extractable acids by treatment of the matter soluble in light petroleum with lead salts were increased in the sterol-fed rat. The increases in the "solid" acid fractions were shown, by ester fractional distillation, to be accounted for mainly by palmitic acid. Esterification of the matter insoluble in light petroleum with methanol and chromatography of the esters on alumina resulted in the separation of fractions which might consist of bile acids with or without keto groups.

Only a part of the large increase in acids soluble in light petroleum can be accounted for as esterified to cholesterol. It is suggested that cholesterol is, in part, converted into acids which appear in the fraction soluble in light petroleum.

6. Results of balance experiments on rats given cholesterol are summarised and discussed. The effect of cholesterol supplements on the faecal excretion of volatile fatty acids in rats given diets with or without fibre is described also.

A. K. Lough.

2044

ECKLES, N. E., TAYLOR, C. B., CAMPBELL, D. J. and GOULD, R. G. (with KEEGAN, P., KELLY, F. B. (Jr.), DAVIS, C. B. (Jr.) and LATENSER, J.) **The origin of plasma cholesterol and the rates of equilibration of liver, plasma, and erythrocyte cholesterol.** *J. Lab. Clin. Med.*, 1955, **46,** 359–372. [Univ. California Los Alamos Sci. Lab., N. Mex.]

Acetate labelled with ^{14}C was injected intravenously into dogs with the liver removed and control, sham-operated dogs. The hepatectomised animals metabolised the acetate to $^{14}CO_2$ at the same rate as did the controls and, though cholesterol was formed from ^{14}C-acetate in intestine, kidney, lung and skin, almost no ^{14}C-cholesterol was found in the plasma.

When serial liver biopsies were made after injection of ^{14}C-acetate the maximum concentration of ^{14}C in the free cholesterol of liver was found after 40 min.; the specific activity of the free sterol was greater than that in ester combination.

Labelled acetate given by mouth appeared in the cholesterol of the blood of intact dogs first in the plasma free sterol, then in the red cells and last in the esterified cholesterol of plasma. The rates of equilibration, expressed as half-times, were estimated to be about 20 min. between free cholesterol in liver and plasma, 1·4 hr. for the plasma free cholesterol and red cell cholesterol system and about 7 hr. for the whole blood free cholesterol and plasma esterified cholesterol system.—G. A. Garton.

2045

DAM, H., PRANGE, I. and SØNDERGAARD, E. **Influence of various levels of dietary cholesterol on the cholesterol content of certain organs and of bile of chicks fed fat-free and peanut oil containing diets.** *Acta physiol. scand.*, 1955, **34,** 141–146. [Dept. Biochem. Nutrit., Polytec. Inst., Copenhagen.]

Groups of 13-day-old chicks were fed on diets containing different amounts of cholesterol; the diets to which the cholesterol was added were either fat-free or contained 10 per cent. groundnut oil. At the end of 4 weeks liver, spleen, aorta and the bile were taken for estimation of total cholesterol.

With diets containing groundnut oil, accumulation of cholesterol was found in all tissues examined when the diet contained from 0·1 to 0·33 per cent. cholesterol. This limit also obtained for fat-free diets for liver, spleen and probably aorta, but in bile only slight accumulation of cholesterol was found when dietary cholesterol ranged from 0 to 1 per cent.—G. A. Garton.

KRÜSKEMPER, H. L. and SCHULZE, G. Über das Verhalten von Lipiden und Fermenten in der Leber bei langdauernder Cholesterinfütterung. [**Lipids and enzymes in the liver after long-continued feeding with cholesterol.**] *Arch. exp. Pathol. Pharmakol.*, 1955, **227,** 161–168. [Med. Klin., Univ. Göttingen.]

For previous work see Abst. 620, Vol. 25.

The 14 rabbits were given cholesterol as described in the earlier paper, and 8 controls received stock diet. After up to 89 days studies were made on the liver.

In the rabbits given cholesterol there was a high total liver lipid content, due mainly to increases in neutral fat and ester cholesterol. There was little change in free cholesterol, free fatty acids or phosphatides.

Respiratory activity of liver tissue was depressed. Acid phosphatase was increased and lipase reduced, but cholinesterase was unchanged. It was concluded that there was no general interference with liver function, but a shift in the fat metabolism in favour of increased fatty acid formation.—D. Duncan.

2047

DURY, A. **The effects of high cholesterol diet alone and plus cortisone administration on phospholipid turnover and lipid partition in plasma, liver, and aorta of rabbits.** *Amer. J. Med. Sci.*, 1955, **230,** 427–435. [Dorn Lab. Med. Res., Bradford Hosp., Bradford, Pa.] Interlingua summary.

Intravenous injection of cortisone acetate into rabbits on a diet rich in cholesterol did not affect the high plasma cholesterol, plasma phospholipin and liver cholesterol or the low liver phospholipin. The normal concentration of neutral fat in plasma and liver of the rabbits on the high-cholesterol diet was increased by treatment with cortisone. Aortic cholesterol concentration in rabbits on the high-cholesterol diet was of the same order whether they received cortisone or not, and slightly higher than in rabbits on control diet.

The specific activities of phospholipin in the aorta were similar in the groups on control diet, high-cholesterol diet and high-cholesterol diet plus cortisone. Cortisone did not affect the specific activity of liver phospholipin in the rabbits on the high-cholesterol diet, although it increased the specific activity of plasma phospholipin.—A. K. Lough.

2048

DURY, A. and DI LUZIO, N. R. **Effects of cortisone and epinephrine exhibition on lipid components and phospholipid turnover in plasma, liver and aorta of rabbits.** *Amer. J. Physiol.*, 1955, **182,** 45–50. [Dorn Lab. Med. Res., Bradford Hosp., Pa.]

2049

BEHER, W. T. and ANTHONY, W. L. **Effects of β-sitosterol and ferric chloride on accumulation of cholesterol in mouse liver.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 223–225. [Edsel B. Ford Inst. Med. Res., Henry Ford Hosp., Detroit, Mich.]

Groups of female mice were fed to appetite on a basal fat-free diet to which were added 1 per cent. cholesterol and 0·25, 0·5 or 1·0 per cent. cholic acid, with or without 2·5 per cent. β-sitosterol. After 3 weeks the livers were removed for estimation of cholesterol.

Total liver cholesterol increased with increasing amounts of dietary cholic acid; the addition of β-sitosterol to the diets containing cholic acid and cholesterol reduced total liver cholesterol.

In similar experiments groups of mice were fed on a diet containing 1 per cent. or 0·5 per cent. cholesterol to which was added 0·05, 0·5, 1·0 or 2·0 per cent. $FeCl_3$. The addition of $FeCl_3$ to the diet did not prevent accumulation of dietary cholesterol in the liver.—G. A. Garton.

2050

HAROLD, F. M., JAYKO, M. E. and CHAIKOFF, I. L. **Metabolism of epicholesterol-4-C^{14} in the rat.** *J. Biol. Chem.*, 1955, **216,** 439–447. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Epicholesterol-4-^{14}C was administered intravenously to adult rats. Within 8 hr. about half the ^{14}C injected was recovered from the bile and about 0·6 per cent. from the faeces and most of the rest was found in the liver. Some 90 per cent. of the bile ^{14}C was in bile acids, which closely resembled, but were not identical with, those resulting from the metabolism of cholesterol-4-^{14}C. Over 80 per cent. of the ^{14}C in the liver was accounted for as dihydrocholesterol. No ^{14}C was found in cholesterol from the bile, faeces or liver.

It is concluded that epicholesterol is not an intermediate in the conversion of cholesterol to bile acids.—A. K. Lough.

GAMBASSI, G. and MAGGI, V. Glutatione e aterosclerosi sperimentale colesterolica: rapporti tra il tripeptide e l'azione antiateromasica dell'acido adenosintrifosforico. [**Glutathione and experimental cholesterol atherosclerosis: relation between the tripeptide and the effect of adenosine triphosphoric acid against atheroma.**] *Acta gerontol.*, 1955, **5**, 235–240. [Ist. Clin. Med., Univ. Ferrara.] French and English summaries.

For earlier work see Title 4683, Vol. 23.

Four groups of 8 rabbits received a stock diet with 0·5 g. cholesterol in olive oil daily for 140 days. The first group were controls, the other groups received adenosine triphosphate (ATP) daily, 2·5 or 1 mg. intravenously or 2·5 mg. subcutaneously. The effects on glutathione in liver and kidney were compared with those found in the earlier experiment, when 2 groups of 8 rabbits had received 1 g. cholesterol daily for 50 days and 1 group had 2·5 mg. ATP subcutaneously daily.

After 50 days the rabbits given ATP subcutaneously had significantly higher glutathione values in liver and kidney then those without ATP. After 140 days the liver glutathione was significantly increased by ATP given subcutaneously, but differences with ATP by vein were not significant, nor were those in kidney glutathione values. Further analyses (Title 5317, Vol. 25; *Arch. Maragliano*, 1954, **9**, 1061) showed the greatest increase in liver fat to be in the rabbits given intravenous ATP and the least in controls, and the only group without atherosclerosis to be those given ATP subcutaneously.—D. Duncan.

MIANI, N., MARINI, I. and AMADUCCI, L. Metabolismo dei fosfolipidi nell'apparato nervoso centrale durante l'accrescimento organico. Ricerche *in vivo* con P^{32}. [**Phospholipin metabolism in the central nervous system during organic growth. Studies *in vivo* with ^{32}P.**] *Arch. Sci. biol., Bologna*, 1955, **39**, 498–511. [Ist. Anat. Umana, Univ. Padua.]

The 8 groups of 8 rats had mean bodyweights, in g., of 5, 16, 28, 36, 50, 100, 175 and 250; the youngest were 3 hr. old. Each animal received an intraperitoneal injection of Na_2HPO_4 in isotonic salt solution, containing ^{32}P to provide 0·05 μC. per g. bodyweight. Half the animals of each group were killed 24 hr. and half 48 hr. after the injection. The distribution of ^{32}P in the phospholipins of the central nervous system was studied.

The greatest incorporation of ^{32}P into phospholipins occurred in the youngest rats. In the first 2 days of life it was greatest in the spinal cord and least in the mesencephalon and proencephalon. The rate of incorporation fell steeply as the bodyweight rose to 50 g., at which time phospholipin formation was greatest in the cerebellum and again least in the mesencephalon and proencephalon. The rate then declined slowly as body growth continued, in all parts except the mesencephalon and proencephalon, where it increased between the bodyweights of 50 and 100 g.

The changes in phospholipin formation in the different parts of the central nervous system appear to be closely related to the time of myelination.—D. Duncan.

MURCHAKOVA, A. F. Lipoidnyi fosfor v pecheni krolika pri obychnom pitanii i pri golodanii. [**Lipoid phosphorus in the liver of the rabbit on an adequate diet and in starvation.**] *Fiziol. Zh. SSSR Sechenova*, 1955, **41**, 265. [Inst. Fiziol. I.P. Pavlova, Akad. Nauk SSSR, Leningrad.]

Lipoid P, acid-insoluble P and total P were estimated in small pieces of liver from rabbits fed on a standard diet and again after starvation for 7 and for 12 or 13 days. There was an increase in all the components during starvation, depending on the nutritional status and period of starvation of the animals. Total P increased by 8 to 41 per cent., falling slightly just before death. This increase was proportional to loss of weight and utilisation of tissue reserves. Acid-insoluble P increased by 16 to 86 per cent. and was derived from both lipoid- and protein-bound P, but just before death it was derived almost entirely from protein-bound P. Lipoid P rose by 26 to 50 per cent., but fell somewhat before death. These changes are held to imply formation of phosphatides in the course of the breakdown and utilisation of fat stores of the body.—D. W. Taylor.

BASS, D. E., KLEEMAN, C. R., QUINN, M., HENSCHEL, A. and HEGNAUER, A. H. **Mechanisms of acclimatization to heat in man.** *Medicine, Baltimore,* 1955, **34,** 323–380. [Quartermasters Res. and Development Command, Natick, Mass.]

Five young soldiers were the subjects in an experiment divided into 3 periods, a control of 21, an experimental of 14 and a recovery period of 12 days. During these times the men lived in a constant-temperature chamber at 75° to 77° F. in the control and recovery periods; in the middle period day temperature was 120° and night temperature 100° F., days and nights being of equal duration. The standard task was walking on a treadmill for 60 min. at 4 m.p.h. each forenoon and afternoon. Physiological and biochemical studies were of antipyrine and thiocyanate spaces, blood volume, composition of sweat, electrolyte balances, adrenocortical activity, pulse rate and rectal temperature.

The results for pulse rate during walking, rectal temperature and rate of sweating showed by decreases in the first 2 measurements and an increase in the third that the men became acclimatised during the first week. Concentrations of Na, Cl, K, N and creatinine in sweat collected under conditions of both rest and exercise fell during the first 4 days; the last 2 of these differed from the others in being lower in exercise than in resting specimens.

Thiocyanate space, plasma volume and blood volume reached their highest levels on the 5th day of treatment; the increase was relatively greater for plasma volume than for thiocyanate space. By the end of the hot period both were about 16 per cent. above the level in the control period. Values for electrolytes in urine showed that, by reduction in losses of Na and Cl, the losses in sweat were more than balanced and, in this way, the kidney maintained the osmotic pressure of the increased extracellular fluid. Balances of water, N, P, K, Na and Cl were measured but, because of practical difficulties, the data for Na and Cl were concluded to be erroneous. The negative balances of N, P and K ran parallel and suggested that heat stress gave rise to some breakdown of tissue. Plasma Mg did not change significantly. The only evidence of alteration in adrenocortical activity was a reduction of the Na : K ratio in urine during the early days of exposure to heat; during that period 17-ketosteroids were present in equal or slightly smaller amounts than during the control period.

The results are fully discussed and the literature is reviewed in detail.—D. Harvey.

KING, J. T., LEE, Y. C. P. and VISSCHER, M. B. **Heart failure in mice related to minerals in diet.** *J. Nutrition,* 1955, **57,** 111–120. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

Heart failure is reported in mice of strain C_3H fed on a diet of glucose 33, casein 28, lard 17, dried brewer's yeast 8, alfalfa leaf 4, cod liver oil 2, wheat germ oil 1 and salts 4 parts. The salt mixture was that of Jones and Foster (Abst. 2417, Vol. 12), with iodised table salt. The heart lesions suggested vitamin E deficiency.

When the modified Jones and Foster salts were replaced by a modification of the salt mixture of Hubbell *et al.* (Abst. 3505, Vol. 7) from which the elements Mn, F, Al and Cu had been omitted there was no heart failure. Multiplying the trace element content of the modified Jones and Foster salts by 10 and decreasing the vitamin E content of the diet by the omission of wheat germ oil increased the incidence of heart failure and reduced the time of survival.—C. F. Mills.

BRINE, C. L. and JOHNSTON, F. A. **Factors affecting calcium absorption by adults.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 883–888. [New York State Coll. Home Econ.]

From a review of the literature, protein and vitamin D in the diet are shown to improve Ca absorption; Ca absorption is reduced by phytates if the diet is rich in phytates and low in Ca and, to a less extent, by oxalates. Less Ca is absorbed when energy intake is reduced and during inactivity. When Ca intake is increased more Ca is absorbed, but the percentage absorbed is less. The amounts of phosphate and of fat in the diet have no effect on Ca absorption.—G. F. Garton.

LENKEIT, W. Regulierung des Mineralstoffwechsels und die Calcium-Phosphor-Bilanz während der Laktation (mit Versuchen an säugenden Sauen). **Regulation of mineral metabolism and calcium and phosphorus balance during lactation, with studies on suckling sows.**] *Wiss. Abh. Deutsch. Akad. Landwirtsch.*, 1954, **5,** No. 2, 407–426. [Inst. Tierphysiol. Tierernähr., Univ. Göttingen.]

The part played in mineral regulation by base or acid excess is discussed. In balance studies with pigs an acid diet led to much ammonia formation, but had little effect during 20 days on the Ca balance. In ruminants, adapted to diets with a large base excess, there is limited ability for regulation against acid excess. The importance of neutralisation of fermentation products in the rumen by saliva is discussed.

Long-term Ca and P balances were made on 4 sows during lactation. Only one had negative balances until the sixth week of lactation; in all 4 the balances rose steadily throughout lactation although intakes were constant. The Ca and P output in milk fell only slowly, and there was no relation between the output in milk and the balance, which rose as excretion in the faeces fell. It is concluded that this could be due only to a changing rate of bone metabolism; milk formation and bone metabolism are independently affected by endocrine control. Negative or low positive Ca and P balances early in lactation may be ascribed to the increase in bone resorption.

BENZIE, D., BOYNE, A. W., DALGARNO, A. C., DUCKWORTH, J., HILL, R. and WALKER, D. M. **Studies of the skeleton of the sheep. 1. The effect of different levels of dietary calcium during pregnancy and lactation on individual bones.** *J. Agric. Sci.*, 1955, **46,** 425–440. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Groups of ewes were given rations which supplied 1·4, 4·5 or 7·4 g. Ca daily, during pregnancy and lactation. No effect was observed on number of lambs born, birthweight or growth to weaning. Blood Ca and inorganic P were estimated monthly. In the group getting only 1·4 g. Ca daily, serum Ca fell lower at parturition than in the other groups, and during lactation it remained lower. During the final stages of lactation, while in this group serum Ca continued to fall, there was a rise of serum Ca in ewes getting 4·5 or 7·4 g. Ca daily. Resorption of bone was estimated from the ash of the skeleton, as absolute weight and as percentage of fat-free bone, and by X-ray studies. Resorption was greatest in the group getting least Ca daily. In a skeleton there was variation in the degree of resorption of different bones and different regions of the long bones. The greatest resorption was in vertebrae and pelvis, the least in the metacarpal, the metatarsal and the shafts of the long bones. This was indicated by the weight of ash of the bones, and, less clearly, by the percentage of ash, and was confirmed by X-ray studies of flesh-free bones.—T. D. Bell.

MOORE, J. H. and TYLER, C. **Studies on the intestinal absorption and excretion of calcium and phosphorus in the pig. 3. The effect of beryllium carbonate on the absorption of phosphorus.** *Brit. J. Nutrition*, 1955, **9,** 389–397. [Dept. Agric. Chem., Univ. Reading.]

Two pigs 9 to 10 weeks old were fed on the diet used in previous experiments (Abst. 3872, Vol. 25), except that beryllium carbonate was introduced gradually until the diet contained 2·4 per cent. The animals were fed on this diet for 10 days and were killed 4 hr. after the morning feed on the eleventh day. The results of analyses of the contents of the digestive tracts of these pigs were compared with those obtained from pigs which received no Be.

In the animals given Be low solubility of total P in the second section of the stomach, little hydrolysis of phytate in the first sections of the tract, and high total P content of the large intestine indicated reduced absorption of P in the presence of Be. This effect was caused chiefly by a reduction in phytate hydrolysis, but partly by the precipitation of phosphate as the Be salt. Be reduced phytate hydrolysis by precipitating phytate, but it also apparently exerted a direct inhibitory effect on phytase.—R. Hill.

SAGER, R. H. and SPARGO, B. **The effects of a low phosphorus ration on calcium metabolism in**

the rat with the production of calcium citrate urinary calculi. *Metabolism*, 1955, **4**, 519–530. [Zoller Dent. Clin., Univ. Chicago, Ill.]

Studies were made on 77 rats aged 3 months; 2 groups each of 5 were not depleted and 10 groups of 5, 6 or 10 animals were depleted of 25 per cent. of their original bodyweight on a diet with 3 per cent. fibrin as the only protein. The protein-depleted rats developed calcium citrate calculi after 6 days on a normal-Ca low-P ration. From skeletal X-ray films, parathyroid measurement and balance studies it was found that the low P ration increased the amount of Ca absorbed from the intestine and hence the non-protein-bound blood Ca. This effect was intensified by the low blood protein resulting from simultaneous protein deficiency. The Ca and citrate in urine were high, with resulting formation of calcium citrate calculi.

BASSIR, O. **The effect of low-calcium diet on tissue metabolism.** *J. Trop. Med. Hyg.*, 1955, **58**, 210–216. [Human Nutrit. Unit, Med. Res. Counc. Labs., London, N.W.3.]

One group of 6 rats 5 weeks old was given a diet (1) of egg white 13·5, sugar 9, potato starch 64·8 and margarine 10 parts; a similar group received diet (2) of similar composition, but containing, in addition, $Na_2HPO_4 . 12H_2O$ 1·11 and Ca- and P-free salts 2·7 parts; 3 similar rats received a diet (3) of lard 12, sugar 50, Solka Floc 6, casein 22, yeasts 5 and salt mixture 5 per cent. All the diets were given for 3 weeks. Parallel experiments with rats 6 to 9 months old were made with diets (2), (3) and also (4), which contained egg white 21, sugar 10, potato starch 48·68, margarine 13, $Na_2HPO_4 . 12H_2O$ 3 and $CaHPO_4 . 2H_2O$ 3 parts. Each animal received every third day vitamin B_1 60 μg., riboflavin 240 μg., pyridoxine 60 μg., Ca pantothenate 1·8 mg., inositol 6 mg., nicotinic acid 6 mg., choline hydrochloride 18 mg., *p*-aminobenzoic acid 18 mg. and cod liver oil 0·5 ml. Distilled water was given throughout the experiment. Rats on diet (3) were controls. Two hr. before the end of the experiment each rat was injected intraperitoneally with about 50 μC. of ^{32}P as phosphate; after death the livers were removed for fractionation of total acid-soluble, ribonucleic acid, deoxyribonucleic acid, adenylic acid and total acid-insoluble P components, and each was tested for ^{32}P activity.

The young rats on diet (1) did not achieve positive Ca or P balance during the experiment; those on diet (2) remained in positive balance. The mature rats on diet (2) were unable to remain in positive Ca and P balance; diet (4) was the best for maintaining Ca and P balance. The amounts of Ca and P in the diet did not affect the rate of renewal of either the acid-soluble or the nucleoprotein cell components in the liver when other dietary constituents were present in adequate amounts. In the skeleton a slowing down of turnover occurred in both young and old rats, although the levels of metabolism differed. Blood P values were significantly different in young rats, higher on diet (2) than on diet (1); mature rats on diet (4) did not show a blood P content significantly higher than that of those on diet (2). The liver size remained constant throughout all the experiments. The reduction in Ca and P intake, as well as unsuitable Ca : P ratios, produced widening of the layer of uncalcified cells between the cartilage and bone of the rib.—G. F. Garton.

VALETTE, G. and CALDERON, C. E. Effet de la teneur du régime alimentaire en calcium sur la sensibilité du cobaye à l'histamine. [**Effect of the calcium content of the ration on histamine sensitivity in the guineapig.**] *C.R. Acad. Sci.*, 1955, **241**, 1620–1621.

Four guineapigs weighing 150 to 200 g. and previously shown to be resistant to the effects of histamine aerosol on the bronchi received a stock diet and 8 a diet low in Ca. After 5 days the 4 controls were still resistant to histamine, but the low-Ca group showed bronchospasm after from 80 to 200 sec. When the 4 controls were given the low-Ca diet 2 became sensitive to histamine after 5 days and the other 2 had become slightly sensitive after 9 days. The 8 which had received the low-Ca diet first were given the stock diet with the addition of condensed milk; 4 were resistant to histamine after 5 days, the other 4 showed bronchospasm after an increased time of exposure.

In a second experiment, calcium gluconate produced histamine resistance both in animals previously on a low-Ca diet and in normally resistant guineapigs newly arrived at the laboratory.

BAUER, G. C. H., CARLSON, A. and LINDQUIST, B. **Bone salt formation measured in infants by means of P^{32}.** *Acta paediat.* 1955, **44**, 477–486. [Dept. Pharmacol., Univ. Lund.] French, German and Spanish summaries.

Computations of the rate of accretion of bone salt from the equation

$$A = \frac{^{32}P_{obs.}}{T \times S_M},$$

where A = rate of accretion, T = interval of time between administration of ^{32}P and observation, S_M = average specific activity of serum P during this interval, and $^{32}P_{obs.}$ = total amount of ^{32}P in inorganic portion of a calcified tissue, had been shown to be valid in rats.

The subjects were 4 infants aged from 5 to 15 months, 2 healthy and 2 with mongolism. Each received a single intramuscular injection of inorganic phosphates providing 2 μC. ^{32}P per kg. bodyweight. Capillary blood samples were taken $\frac{1}{4}$, $\frac{1}{2}$, 2, 3, 4, 8, 12 and 24 hr. later and urine was collected for 16 to 18 days. Bone specimens were taken from the tibiae 7 and 16 days after administration of ^{32}P.

The equation given above was valid for the infants. The rate of accretion was higher in spongy than in compact bone, so spongy bone should be carefully removed from samples. The mean values for A, expressed as mg. P per mg. P of bone specimen daily, were 0·016 and 0·011 for the 2 healthy infants, 0·02 for one mongoloid who was the youngest and smallest of the series, and 0·0057 for the other, who had a serum inorganic P value of only 4·1 mg. per 100 ml. and may have been deficient in vitamin D.

The values for the healthy infants corresponded to about 0·05 per cent. per hour, or 5 times the net increase in P.—D. Duncan.

2069

CARTIER, P. L'affinité du squelette du rat en croissance pour le radiophosphore. [**The affinity of the rat skeleton during growth for radioactive phosphorus.**] *C.R. Acad. Sci.*, 1955, **241,** 1632–1634.

Littermate rats received at different ages a single injection of 50 to 100 μC. carrier-free $NaH_2{}^{32}PO_4$ and were killed 24 hr. later. The P content and radio-activity of the centrodiaphyseal parts of both femurs were estimated.

The ^{32}P uptake of the bone depended on the degree of mineralisation; it was high during growth and had a low and constant value in adult rats. There was a sharp break in the curve shortly after puberty. The uptake of ^{32}P was inversely related to the degree of saturation of the protein matrix with minerals, for which it can provide a test.—D. Duncan.

BACHRA, B. N. and WÖSTMANN, B. S. J. **Phosphate and radiophosphate clearance in the white rat after intraperitoneal administration of P^{32}.** *Arch. internat. Physiol.*, 1955, **63,** 273–290. [Lab. Physiol. Chem., Municipal Univ., Amsterdam.]

The subjects were rats weighing about 200 g., which had been kept for at least 3 months on stock diet. For the experiment the rat received by tube water equal to 5 per cent. of the bodyweight, the bladder was catheterised under light ether narcosis and then pentobarbital was given at 40 mg. per kg. bodyweight. Heparin was injected, then 1·5 ml. of 10 per cent. inulin solution, 40 min. before the collection period began, and 100 μC. almost carrier-free ^{32}P as Na_2HPO_4, 15 min. before collection. Urine was collected for 30 min. In one series of experiments the ^{32}P was given 24 hr. before the collection period. Blood was sampled every 10 min. during urine collection, after which the rat was decapitated and total blood was centrifuged for plasma.

Urine collected 15 min. after injection of ^{32}P showed more specific activity than did acid-soluble plasma phosphate; the average ratio was 2·3 : 1. At 24 hr. after injection there was no such difference; the ratio was unity.

Leakage of ^{32}P from the intraperitoneal space into the renal pelvis, ureters or bladder was considered improbable, because excretion of ^{32}P by rachitic animals in similar experiments was so slight and if leakage occurred it would be expected equally in normal and rachitic rats. When other possible sources of error are considered it is concluded that readily filtrable ionic phosphate comprises a fraction much less than 43 per cent. of the total inorganic P fraction in plasma, the rest being apparently in slowly filtrable complexes. The normal clearance values for phosphate reported in the literature are thought to be too small to represent the ionic phosphate.—D. Duncan.

2071

MONEY, W. L. and RAWSON, R. W. **Uptake of P^{32} by chick thyroid and testes following pituitary administration, iodine deficiency and thiouracil.** *Amer. J. Physiol.*, 1955, **182,** 1–4. [Sloan-Kettering Inst., Mem. Centre, New York.]

Twenty cockerels, 1 to 11 days old, were injected subcutaneously with a single dose of 1 ml. of a pituitary preparation containing thyroid-stimulating hormone and gonadotropic hormones; 2 hr. later the chicks and 20 controls received 10 μC. carrier-free ^{32}P injected in the same manner. After 1, 2, 4, and 24 hr., 5 treated and 5 control chicks were killed and the ^{32}P of thyroids and testes was estimated. Within 1 hr. the thyroids and testes of the chicks treated with the pituitary preparation had collected about twice as much radio-activity as those of the controls.

Another similar group of chicks was maintained on a low-iodine diet for a week and then given injections of the pituitary preparation and ^{32}P as before, and all were killed 24 hr. later. The concentration of ^{32}P in the thyroids and testes was not so consistently high as in the previous experiment, but it had increased more than in similarly treated chicks maintained on a stock Purina diet. A group of chicks on the low-iodine diet without injections of pituitary preparation concentrated more ^{32}P in the thyroids and testes than comparable chicks on the Purina diet. When chicks were

given a diet containing 0·1 per cent. thiouracil for 4 days and were then injected with the pituitary preparation and ^{32}P there was again an increase in ^{32}P in the thyroids and testes, but without the pituitary preparation the testes did not concentrate ^{32}P, although the thyroids did.

It is suggested that the greater concentration of ^{32}P by the thyroids of chicks on a low-iodine diet deserves further investigation.—B. W. Simpson.

2072

LANG, K., SCHACHINGER, L., KARGES, O., BLUMENBERG, F. K., ROSSMÜLLER, G. and SCHMUTTE, I. Der Stoffwechsel von Polyphosphaten. [**Metabolism of polyphosphates.**] *Biochem. Ztschr.*, 1955, **327,** 118–125. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

Rats received a basal diet of two parts wheat flour to one of whole dried milk, with 1 per cent. torula yeast. After daily output of inorganic and total P in urine and faeces had been studied, the rats received for 8 days a diet containing 10 per cent. potassium metapolyphosphate and then for 11 days a similar diet with 5 per cent. sodium hexametaphosphate.

From 44 to 59 per cent. of the metapolyphosphate and 37 to 66 per cent. of the hexametaphosphate eaten appeared as such in the faeces, and excretion of orthophosphate in the faeces increased. The slight increase in orthophosphate output in the urine suggested that little of the polyphosphate was absorbed, whether as such or as orthophosphate. There was little or no polyphosphate in urine when hexametaphosphate was given, but 4 to 10 per cent. after metapolyphosphate, though it appeared in the forms of tetrametaphosphate, trimetaphosphate and pyrophosphate.

When polyphosphate was incubated with homogenate of mucosa from rat small intestine there was no evidence of enzymic breakdown.

Hexametaphosphate labelled with ^{32}P was given by stomach tube to 4 rabbits, which were killed after 12 and 24 hr. Only 9·7 per cent. of the ^{32}P was recovered in the tissues, 8·4 per cent. in the skeleton.—D. Duncan.

ROBINSON, S., NICHOLAS, J. R., SMITH, J. H., DALY, W. J. and PEARCY, M. **Time relation of renal and sweat gland adjustments to salt deficiency in men.** *J. Appl. Physiol.*, 1955, **8,** 159–165. [Dept. Physiol., Indiana Univ., Bloomington.]

The subjects, 7 men aged from 19 to 25 years and 1 aged 50, were trained and acclimatised to work in heat. In 6-hr. experiments they walked on a treadmill at 46° C. dry bulb, 26° C. wet bulb. In some experiments they were first depleted of salt by 5 days of low salt intake, 50 m. equiv. daily. They took glucose and water during work in the heat. Other experiments included work in heat and rest in a cooler room for alternate 2-hr. periods for 10 hr. on one day and 4 hr. after a night's rest, or intermittent work for 25 hr. in heat.

Estimated salt deficiencies of from 113 to 407 m. equiv. were produced. The response of the kidney to salt depletion began in 1 to 2 hr. and was in full operation after 5 to 14 hr. On the other hand, reduced output of Na and Cl in sweat did not begin for 8 hr. even in the intermittent experiments, and was delayed for 20 hr. when salt depletion was combined with steady exposure to heat with periods of work. When work and rest alternated in the hot environment, loss of salt in urine was less during work than at rest, but sweat concentration and salt output in sweat were much greater during work.—D. Duncan.

The relationship of alkalosis, potassium deficiency and surgical stress to acute hypokalemia in man. Experiments and review of the literature.** *Metabolism*, 1955, **4,** 379–402. [Dept. Surg., Peter Bent Brigham Hosp., Boston, Mass.]

For previous parts see Absts. 202, 865, 2337, Vol. 25.

Experimental data show that in normal men restricted in K intake, losses of up to 200 m. equiv. K in 5 days may occur without change in serum K.

Metabolic alkalosis, produced by loss of Cl by gastric suction, and the renal Na blockade produced by stress or ACTH favour a fall of serum K and these combined with rapid loss of K produce severe alkalosis with clinical signs and symptoms and electrocardiographic changes.—F. C. Aitken.

FIELD, H. (Jr.), SWELL, L., DAILEY, R. E., TROUT, E. C. and BOYD, R. S. **Electrolyte changes in ileal contents and in feces during restriction of dietary sodium with and without the administration of cation-exchange resin.** *Circulation*, 1955, **12**, 625–629. [Veterans Admin. Centre, Martinsburg, W. Va.] Interlingua summary.

In 4 dogs with fistulae in the terminal ileum, stepwise reduction of Na intake caused stepwise decrease of Na concentration and increase of K concentration in terminal ileum. When Na restriction was accompanied by administration of resin, stepwise decrease of free and bound Na and increase of free K were found, but the Na and K concentrations for each level of intake exceeded those when resin was not given. Bound K increased with moderate Na restriction, but more severe restriction caused no further change.

With each Na intake the amount of bound Na in the terminal ileum exceeded Na intake. The resin retained Na in the faeces of the dogs no matter what the Na intake. The relative retention of Na in the faeces during administration of resin became progressively greater as Na intake was reduced.—F. C. Aitken.

MEYER, J. H. **Influence of dietary levels of sodium chloride and protein on growth, nitrogen balance and body composition of the growing rat.** *Amer. J. Physiol.*, 1955, **182**, 83–88. [Dept. Animal Husb., Univ. California, Davis.]

For previous work see Abst. 3307, Vol. 24.

Weanling rats were fed to appetite on a basal diet containing 10, 25 or 40 per cent. casein or similar diets containing 15 per cent. NaCl or on the amount of basal diet consumed by the second group, but without NaCl.

NaCl depressed growth equally with all levels of casein in the rats fed to appetite, and the gains of fat, water, N, ash, Na and K in the eviscerated rat were less than in controls. The gains of the rats receiving NaCl were greater than those of the pair-fed controls, owing to the increased weight of the digestive tract and its contents. After evisceration total weight, gains of water, Na and K were the same, but gains of N, ash and fat, particularly with the higher casein levels, were higher in the controls.

NaCl produced a small increase in the water and Na content of the carcase, but fat decreased at the higher levels of casein, and N and K were unaffected. The N content of the carcase increased slightly and the ash content decreased when the casein was raised from 10 to 25 per cent. Protein content did not affect the contents of water, Na and K.

Balance studies showed that NaCl increased the digestibility but decreased the retention of N.

FREGLY, M. J. **Hypertension, NaCl aversion and polydipsia in rats. Time course and relation to age.** *Amer. J. Physiol.*, 1955, **182**, 139–144. [Dept. Physiol., Harvard Med. Sch., Boston, Mass.]

When the experiment began 21 rats were aged 10 weeks and weighed about 250 g. and 9 were 20 weeks old and weighed about 360 g. After 2 weeks when food and fluid intakes, bodyweight and blood pressure were measured, both kidneys were encapsulated with latex in 12 rats from the younger and 6 from the older group. Observations were continued weekly for 9 weeks and thereafter for 20 more weeks at intervals of 2 or 3 weeks.

A rise in blood pressure occurred in both groups at about the same time, from 2 to 4 weeks, after operation. Aversion to NaCl solution appeared in the younger rats about 8 weeks after operation when blood pressure was highest; in the older group blood pressure was highest at about 9 weeks, but dislike of salt was inconsistent. Of the operated rats, 7 of the 12 younger but only 2 of the 6 older died during the experiment. There was no difference in growth rate or in food intake between operated and control animals.—D. Harvey.

SCHWARTZ, R., COHEN, J. and WALLACE, W. M. **Distribution of injected potassium salts in tissues of the potassium-deficient rat.** *Amer. J. Physiol.*, 1955, **182**, 39–44. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Young rats fed for 14 days on a diet deficient in K were injected intraperitoneally with K salts during a period of 12 hr. The bodyweight immediately increased. Although the total deficit was 15 m*M* K per kg. bodyweight (see Abst. 4718, Vol. 23), 17 m*M* KCl did not restore serum or muscle composition to normal. Normal values for K in these and for whole body K were obtained after 24 hr. with 25 m*M* K per kg., and Cl increased in muscle. Water was retained and the body fat increased after 4 days. On the fourth day after treatment deficiency had recurred. KCl proved toxic when given more quickly.

In rats given potassium acetate serum Na and Cl and red cell K were high after 24 hr. and returned to normal by the fourth day. K as acetate appeared to be more toxic than as chloride.

FELTMAN, R. and KOSEL, G. **Prenatal ingestion of fluorides and their transfer to the fetus.** *Science*, 1955, **122**, 560–561. [Passaic Gen. Hosp., N.J.]

Four groups of subjects were studied: 20 women who for different lengths of time during pregnancy had had F daily in tablets containing 2 mg. CaF_2 or 2·2 mg. NaF; 146 living nearby and having no extra F; 6 who used water from a fluoridated supply, and 9 getting water from an untreated source. F was estimated in cord blood and in a sample of tissue from the periphery of the placenta. Average values for the groups in the above order were, for blood, 41, 17, 38 and 22 μg. per 100 ml. and for tissue 111, 101, 85 and 67 μg. per 100 g. In 2 placentae, one from each of the first 2 groups, the concentration of F was mapped and is shown diagrammatically. In both it was highest at the periphery.

The importance of the findings cannot yet be finally assessed.—D. Harvey.

KORRODI, H., WEGMANN, T., GALLETTI, P. and HELD, H. R. Sind bei der Cariesprophylaxe mit Fluor Rückwirkungen auf die Schilddrüse zu erwarten? [**Are repercussions on the thyroid to be expected from caries prophylaxis with fluorine?**] *Schweiz. med. Wochenschr.*, 1955, **85**, 1016–1019. [Med. Poliklin., Univ. Zürich.] English summary.

The problem is discussed and literature is reviewed.

Of 30 young rats, half received a normal diet and half a diet low in iodine. For each diet 3 groups were constituted, one receiving 0·05 mg. NaF daily, one receiving 2·0 mg. daily, and one without F. After 7 weeks all the rats were given an intraperitoneal injection of ^{131}I with no further food or NaF; 24 hr. later they were killed. The weight increase of the rats was irregular and no conclusion could be drawn from it. The rats having the diet low in I showed hyperplasia of the thyroid, which absolutely and relatively weighed about 3 times as much as the glands of the rats having normal diet, but there was no clear effect of the added NaF with either diet. The uptake of ^{131}I was much greater in the group having the diet low in I, but within each group was greatest by the rats given the larger dose of NaF.

A group of 10 human subjects received 4·4 mg. NaF daily for 3 months, and another group of 6 had 11 mg. daily for from 3 to 4 weeks. The amount of I bound to protein in the blood serum, uptake of ^{131}I by the thyroid, serum cholesterol and B.M.R. were estimated before and at the end of treatment. With the smaller dose there was no consistent change, but with the larger dose the amount of protein-bound I fell and uptake of ^{131}I increased. The subjects showed no sign of toxicity, and in one of them with Graves' disease there was no effect on the illness. The amount of F given in the smaller dose was greater than the amount likely to be given for prevention of caries.

PERKINSON, J. D. (Jr.), WHITNEY, I. B., MONROE, R. A., LOTZ, W. E. and COMAR, C. L. **Metabolism of fluorine 18 in domestic animals.** *Amer. J. Physiol.*, 1955, **182**, 383–389. [Univ. Tennessee-Atomic Energy Commission Agric. Res. Programme, Oak Ridge.]

^{18}F with a half-life of 1·87 hr. allows study for up to 10 hr. with non-toxic levels of total F. In the preparation of the isotope ^{22}Na appears simultaneously; some data are given for its metabolism.

When ^{18}F was injected intravenously into 6-month-old lambs the initial rate of disappearance from the blood was 41 per cent. of the dose per minute; for a cow it was 32 per cent. When given by mouth both ^{18}F and ^{22}Na appeared in blood as early as 5 min. after administration, suggesting absorption from the rumen. The concentration of ^{18}F in blood rose to a maximum 180 min. after administration and then fell; that of ^{22}Na continued to rise during the whole 609 min. of observation.

Excretion into the digestive tract was studied in lambs killed 2 hr. after administration by one or other route. Nearly all that given by mouth was then in the rumen; 5 per cent. of that given intravenously was in the digestive tract, 4 per cent. in the rumen and reticulum and 1 per cent. in the large intestine. The distribution in tissues was

studied in another lamb given the isotope by mouth and killed 2 hr. later. In the femur deposition was heavy in the primary spongiosa below the epiphyseal plate; in the mandible it was heaviest around the enamel of the unerupted molar.

The incorporation of ^{18}F given to hens was studied in the developing eggs. Accumulation was highest in the shell, and, with one exception, the concentration in the albumin was higher than in the yolk.

In the lactating cow after ingestion the concentration in milk was parallel to, but lower than, that in blood; after injection the concentration in milk rose rapidly to a peak at about 100 min. and then fell, the curve being parallel to and below that for the concentration in blood.—D. Harvey.

MILLER, R. F. and PHILLIPS, P. H. **The enhancement of the toxicity of sodium fluoride in the rat by high dietary fat.** *J. Nutrition*, 1955, **56,** 447–454. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of individually caged female weanling rats were fed for 42 to 50 days on purified diets containing 0·1 per cent. NaF and from 5 to 15 per cent. cottonseed oil or butterfat.

The growth-retarding effect of NaF increased with increasing proportion of fat in the diet and was not altered by supplements of pantothenate, methionine or ascorbic acid alone or in combination. The development of fluorosis, accelerated by fat, was unaffected by subcutaneous or intraperitoneal injection of adenosine triphosphate, pantothenate or cysteine alone or in combination. Since cottonseed oil and butterfat were equally effective in promoting fluorosis, the property could not be attributed to the average chain length of the component fatty acids, which differed considerably. The retardation of growth in these experiments was accompanied by increased deposition of F in the femurs.—G. A. Garton.

WRIGHT, E. and ANDREWS, E. D. **Availability of iodate iodine to sheep.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37,** 83–87. [Animal Res. Stat., Dept. Agric., Wallaceville.]

^{131}I was incorporated into potassium iodide and iodate. Solutions of one or other were given by stomach tube to 6 one-year-old Romney wethers which were kept without food for 24 hr. before and 48 hr. after. Each sheep got 25 μC. per dose, corresponding to about 10 μC. per g. thyroid tissue, on the assumption that the thyroid weighed about 2·5 g. The uptake of ^{131}I by the thyroids was measured every 20 hr. for 220 hr. Three tests were made at intervals of 1 month.

For 4 of the sheep the effect of KI was similar to that of iodate; the thyroid took up about 70 per cent. of the dose at the maximum. In the other 2 sheep the uptake from iodate was only 45 per cent. of the dose. The amounts of ^{131}I concentrated in the glands were sufficient to justify the conclusion that the I of iodate was almost as available as that of iodide, and the former had the advantage of being more stable when incorporated into salt blocks and was as easily obtainable.

SMITH, C. A., CHERRY, R. B., MALETSKOS, C. J., GIBSON, J. G. (2nd), ROBY, C. C., CATON, W. L. and REID, D. E. **Persistence and utilization of maternal iron for blood formation during infancy.** *J. Clin. Invest.*, 1955, **34,** 1391–1402. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Sixteen infants from 11 mothers who had received, on 4 to 7 occasions during pregnancy, transfusions of red blood cells containing ^{55}Fe were studied. Red and white cell counts, Hb, haematocrit, total Fe and the ^{55}Fe content of red cells were estimated in maternal venous blood and cord blood samples obtained at delivery and in samples of the infants' venous blood obtained at intervals up to 32 months of age. The mothers and infants were similar in diet, hygiene and general health to the population of any obstetrical hospital or baby clinic in the Boston area. The total activity of ^{55}Fe administered to each pregnant woman ranged from 2 to 12 μC.

Results from the 16 infants as a group indicated that little or no dietary Fe was used for formation of Hb until 3 to 4 months after birth. At 1 year Fe which had been transported across the placenta formed 70 per cent. of total Hb iron and, at 2 years, 40 per cent.; these values mean that 170 mg. of Fe transported across the placenta was in circulation at birth, 200 mg. at 1 year and 160 mg. at 2 years. The increase in transported Fe which

occurred at 200 to 400 days is believed to be due to utilisation of Fe stored during foetal life; infants with relatively low total circulating Hb at birth tended to show relatively large amounts of such stored Fe in Hb later. Individual infants showed deviation from the general pattern for the group; a premature infant of 36 weeks' gestation had low total circulating Hb at birth, no evidence of any stored Fe in later Hb formation and a proportionately high utilisation of dietary Fe, which first appeared in the Hb 65 days after birth.

RECHENBERGER, J. Die Eisenversorgung des Neugeborenen und Säuglings. [**The iron supply of the newborn and suckling.**] *Deutsch. Ztschr. Verdaungs- u. Stoffwechselkr.*, 1955, **15,** 228–237. [Med. Klin., Univ. Leipzig.]

A brief resumé is given of findings in the literature (see *e.g.*, Abst. 1825, Vol. 1) on the different ways in which Fe is supplied to the young of different species. To throw further light on the problem in man, Fe, total and as Hb, was estimated by the methods of Rechenberger and Schairer (Title 3641, Vol. 20) in the bodies, liver, spleen, and blood serum of 51 deceased infants, some premature.

The results are given in a diagram, which shows that during the first 3 months of life a "wave" of Fe passes through the body. At birth Fe present as Hb amounts to 190 mg., but falls very rapidly; the store of Fe in the liver is small, only about 20 mg., but it rises rapidly as excess Hb is broken down, and then declines gradually during the first year or until suitable foods other than milk are given.

It is calculated that the Fe lost by the mother at delivery amounts to about 500 mg., about half being in the infant. Allowing for 250 mg. saved by the cessation of menstruation, the mother has to supply 250 mg., which could be more than covered by absorption of 1 mg. from the food daily during pregnancy. A warning is included against applying to women the results of experiments on animals, *e.g.* rats, with different arrangements for supplying Fe and different types of placenta. If treatment with Fe is needed, the physiologically soundest method is to give it to the mother by mouth during pregnancy, especially the second half.—W. M. Deans.

CHAPPELLE, E., GABRIO, B. W., STEVENS, A. R. (Jr.) and FINCH, C. A. **Regulation of body iron content through excretion in the mouse.** *Amer. J. Physiol.*, 1955, **182,** 390–392. [Dept. Med., Sch. Med., Univ. Washington, Seattle.]

Groups of 20 female mice included normal animals and mice with excessive body Fe, with experimentally induced Fe deficiency, with simulated infection produced by turpentine injection and with anaemia produced by administration of acetylphenylhydrazine. Each mouse received an intraperitoneal injection of 0·22 mg. Fe as $^{59}FeCl_3$, equivalent to 0·4 μC. The total body radio-activity was then estimated every 3 to 4 weeks for 196 days by placing the animal in a Texas gamma counter.

Within 2 days after injection of ^{59}Fe a loss of 9 to 15 per cent. of the isotope was recorded; subsequently the rate of loss of ^{59}Fe ranged from 0·29 to 0·73 per cent. daily.—G. F. Garton.

2095

MARKOWITZ, H., GUBLER, C. J., MAHONEY, J. P., CARTWRIGHT, G. E. and WINTROBE, M. M. **Studies on copper metabolism. 14. Copper, ceruloplasmin and oxidase activity in sera of normal human subjects, pregnant women and patients with infection, hepatolenticular degeneration and the nephrotic syndrome.** *J. Clin. Invest.*, 1955, **34,** 1498–1508. [Dept. Med., Univ. Utah Coll. Med., Salt Lake City.]

For part 13 see Title 2366, Vol. 25.

In all groups except the subjects with hepatolenticular degeneration there was a high positive correlation between caeruloplasmin level on the one hand and total plasma Cu, indirect-reacting

fraction of plasma Cu and oxidase on the other. Values were high in infection and higher in pregnancy. Caeruloplasmin values were low in hepatolenticular degeneration, but there was no obvious correlation between the value and the duration or severity of the clinical manifestations of the disease. Low values for caeruloplasmin were found in just over half the patients with the nephrotic syndrome. In these, loss of caeruloplasmin in urine was important.

Some data on caeruloplasmin in tissues are presented.—F. C. Aitken.

2096

MAHONEY, J. P., BUSH, J. A., GUBLER, C. J., MORETZ, W. H., CARTWRIGHT, G. E. and WINTROBE, M. M. **Studies on copper metabolism. 15. The excretion of copper by animals.** *J. Lab. Clin. Med.*, 1955, **46,** 702–708. [Dept. Med. Coll. Med., Univ. Utah, Salt Lake City.]

The excretion of intravenously injected ^{64}Cu was studied in normal dogs, dogs with ligated bile ducts and dogs with the flow of bile diverted to the urinary bladder. Excretion in urine accounted for about 0·6 per cent. of administered ^{64}Cu; 7 to 10 per cent. was excreted in the bile and 1·5 per cent. through the intestinal wall. Ligation of the bile duct increased the output of Cu from kidney and intestine.

Daily intravenous injection of 0·5 mg. non-radio-active Cu per kg. bodyweight resulted in a marked increase of urinary Cu in dogs with obstruction of the bile duct. The renal excretion of Cu by a normal dog was not increased by this treatment.

Ligation of the bile duct of 6 dogs and 4 pigs did not result in high blood Cu values even when 0·5 mg. Cu per kg. bodyweight daily was given by mouth or intravenously. About 70 per cent. of the Cu given was recovered from the liver of a dog that had received 180 mg. Cu intravenously during 34 days and from the liver of a pig given 920 mg. Cu during 57 days.—C. F. Mills.

2097

MILLS, C. F. **Availability of copper in freeze-dried herbage and herbage extracts to copper-deficient rats.** *Brit. J. Nutrition*, 1955, **9,** 398–409. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Herbage supplements and $CuSO_4 . 5H_2O$ in amounts equivalent to the Cu content of the herbage were added to the diet of groups of rats depleted of Cu by a diet of fresh whole milk supplemented with vitamins A, E and those of the B group. The response to dietary Cu was assessed by the extent of blood formation, growth, melanin pigment regeneration and hepatic Cu values.

The herbage supplements gave a greater response and more deposition of Cu in the liver than the $CuSO_4$. The effect was associated with a water-soluble form of Cu which is more readily available than free Cu. No difference in the utilisation of Cu could be demonstrated between normal herbage and that from an area where swayback is common if pregnant ewes are not given a Cu supplement. Possible reasons for this are discussed.

G. F. Garton.

OTHER MINERALS

2098

LEE, C. C. and WOLTERINK, L. F. **Blood and tissue partition of cobalt 60 in dogs.** *Amer. J. Physiol.*, 1955, **183,** 173–177. [Dept. Physiol. Pharmacol., Michigan State Univ., East Lansing.]

Radio-activity was measured in 34 blood samples collected from 5 dogs at intervals after intravenous injection of 20 μg. ^{60}Co as sulphate per kg. bodyweight. Within 12 hr. after injection the blood cells contained insignificant amounts of ^{60}Co. Twelve hr. after one dog had received a similar injection, a high concentration of ^{60}Co was found in the liver, digestive tract, kidney, urine and bile. When a similar amount of ^{60}Co was injected into the lumen of the second loop of the small intestine of another dog, about 50 per cent. of the injected ^{60}Co was absorbed within 12 hr. and was concentrated in the liver, digestive tract, urine, kidney and bile. The ^{60}Co in plasma was about twice as high in the dog which received the intravenous injection as in the dog which received the intra-intestinal injection; in both dogs the spleen contained a small amount of ^{60}Co.—G. F. Garton.

2099

LEE, C. C. and WOLTERINK, L. F. **Metabolism of cobalt 60 in chickens.** *Poultry Sci.*, 1955, **34,** 764–776. [Dept. Physiol., Michigan State Coll., East Lansing.]

Chickens weighing about 1 kg. were given ^{60}Co by vein or directly into the gizzard. Some birds were normal, some had one or both caeca tied off, and some had the large intestine tied off.

In normal birds 24 hr. after intravenous injection 6 per cent. of the ^{60}Co was recovered from the small intestine, 5 per cent. from the caeca, 1 per cent. from the large intestine and 5 per cent. from the extracellular fluid. In the same period at least 13 per cent. was excreted in the faeces, and a large part of the remainder in the urine. With injection into the gizzard 15 per cent. appeared in faeces and only a small amount in the urine.

When the caeca were ligated it was shown that ^{60}Co entered through the wall in large amounts,

although in normal birds the course of entry was through the gut. There were large concentrations in the caecal wall, caecal contents and small and large intestines. There was no great difference in this between the 2 methods of administration. The ^{60}Co in these locations was thought to be in a non-diffusible form. The liver did not seem to remove Co from the blood to the same extent in the chicken as in the dog (see preceding Abst.).

HOCK, A., HORN, V. and PILAR-DIETRICH, A. v. Ernährungseinflüsse auf die Bleiablagerung in den Knochen von Ratten unter chronischer Bleivergiftung. [**Effect of diet on deposition of lead in bones of rats with chronic lead poisoning.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 307–317. [Vet. Physiol. Inst., Justus Liebig Hochsch., Giessen.] English summary.

Eight groups of rats of bodyweight 100 to 120 g., of both sexes, received different diets for 36 or 84 days and twice weekly an intraperitoneal injection of 1 mg. lead as acetate per 100 g. bodyweight. At the end the Pb content of the scapula was estimated and blood and tissues were examined for signs of poisoning.

None of the groups given Pb grew as well as controls given no Pb. No sign of poisoning was found. The only rats which lost weight were those on a diet with 8 per cent. protein, all of plant origin.

The mean Pb content of the scapula in the 20 control rats was 3 mg. per cent. In all the groups given Pb for 80 days the scapulae contained from 68 to 91·6 mg. per cent. The highest mean value, 91·6 mg. per cent., was in rats given a diet containing only 9·5 per cent. crude protein, mostly as dried skimmed milk. The lowest value, 68 mg. per cent., was in rats given what was regarded as an optimum diet, with 20·8 per cent. protein in the form of a mixture of dried whole and skimmed milk, meatmeal, fishmeal, soya bean meal and cereals. With 2 diets containing 16·9 per cent. protein mostly as skimmed milk, and with the 8 per cent. plant protein diet, values were significantly less than the highest. When the diet with 9·5 per cent. protein was supplemented with 0·5 per cent. methionine there was a significant reduction in the amount of Pb deposited. There appeared to be no effect from variations in Ca content between 510 and 803 mg. per cent., in P content between 350 and 834 per cent., or in Ca : P ratio between 1 : 1·12 and 1 : 0·69.

It is concluded that SH groups, produced from methionine via cysteine or by increased breakdown of body proteins in protein deficiency, increased the excretion of Pb. A protein-rich diet may be useful in treatment of lead poisoning.—D. Duncan.

2101

PARKER, H. E., ANDREWS, F. N., CARRICK, C. W., CREEK, R. D. and HAUGE, S. M. **Effect of manganese on bone formation studied with radioactive isotopes.** *Poultry Sci.*, 1955, **34,** 1154–1158. [Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Thirty day-old chicks were divided into 6 groups; 3 groups were fed on a diet containing 10 p.p.m. of manganese, and 3 groups on a diet containing 100 p.p.m. When they were 4 weeks old one low-Mn and one high-Mn group received an injection of radio-active Mn, another pair radio-active Ca and the third pair radio-active P.

Forty-eight hours after injection the tibiae of chicks fed on the low-Mn diet contained more radio-active Mn than those of chicks fed on the high-Mn diet, but the quantities of radio-active Ca and P deposited in the bone were not affected by Mn intake.

Radio-active Mn was deposited throughout the tibiae, but autoradiographs showed greatest concentrations in regions of greatest bone formation.

WOLFF, H. P., RINGLEB, D. and AMANN, R. Histochemische Untersuchungen über das Inselzink. 2. Histophotometrische Messungen. [**Histochemical studies of zinc in the islets of Langerhans. 2. Histophotometric measurements.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 390–416. [Med. Poliklin., Univ. Marburg a.d. Lahn.]

For part 1 see Abst. 2376, Vol. 25.

Adult rabbits and rats were given dithizone solution as before for intravital staining of Zn, but a new method of preparing the solution gave better staining results. It was confirmed that adrenaline and insulin produced a clearly visible decrease in Zn in alpha cells of the pancreas of rats, but the loss of Zn from these cells in starvation could not be confirmed. All the results obtained earlier with rabbits were confirmed.

A photometric method is fully described by which the stained Zn in beta cells of rabbits was estimated quantitatively. In 12 normal rabbits the standard deviation of the values was $\pm$ 4·07 per cent. The absorption values for these 12 rabbits served as the basis for comparison.

In starved rabbits the beta cell Zn increased in the first 4 days by as much as 70 per cent., but after from 5 to 16 days of starvation the values were extremely variable. In 30 rabbits blood sugar and beta cell Zn were studied after a single intravenous injection of 7·5 to 10 g. glucose per kg. bodyweight. There was a significant fall to 20 to 50 per cent. of the initial Zn values 3 to 5 hr. after

the injection. Adrenaline also produced significant falls to about 30 per cent. of normal values in 2 to 5 hr. Carbaminoylcholine produced in 4 rabbits a slight and in 5 a large increase, of up to 120 per cent., in Zn values.

The relation between the Zn values by the above method and the β-granules stained with aldehyde fuchsin was studied. The β-granules showed no change comparable to the changes in stainable Zn produced by starvation and other influences. The possible role of Zn in the function of the beta cells is discussed.—D. Duncan.

ANDERSSON, B. and MCCANN, S. M. **A further study of polydipsia evoked by hypothalamic stimulation in the goat.** *Acta physiol. scand.*, 1955, **33,** 333–346. [Dept. Physiol., Kgl. Vet. Högsk., Stockholm.]

The injection of 0·003 to 0·01 ml. of 2 to 3 per cent. NaCl solution into the region of the hypothalamus of goats caused them to drink excessive quantities of water. Electrical stimulation of the hypothalamus produced the same result. The beginning and end of drinking corresponded closely to the application of stimulation.

Diurnal differences in diuresis after water.**] *Ztschr. Kinderheilk.*, 1955, **77,** 261–270. [Kinderklin., Med. Akad., Düsseldorf.]

Thirty healthy children aged from 5 to 13 years were tested by day, beginning at 7 a.m., with a water load of 30 ml. per kg. bodyweight, by mouth. Most of them had excreted all this after 6 hr.; those who had not were not tested by night. In the night test the children had nothing to eat or drink after 4 p.m. and were roused for the start of the test at 10 p.m. It lasted till 6 a.m. Nearly all showed delayed excretion by night and the sp. gr. of urine rose more slowly than by day; excretion of NaCl showed the same trend as sp. gr. The exceptions were lively children who slept lightly. Of 5 children with prepubertal obesity, 3 showed delayed excretion both day and night. The physiological implications are discussed.

Insensible water loss was measured in 569 tests on 39 subjects under the conditions of ordinary hospital life. The average for patients aged from 2 months to 16 years was 930 ml. per sq. m. per 24 hr. There was a gradual decline with age from an average of 1200 ml. per sq. m. per 24 hr. for young infants to 700 for older adolescents.—F. C. Aitken.

SCHREIBER, M. and ELVEHJEM, C. A. **Water restriction in nutrition studies. 1. Level of**

fat and protein utilization. *J. Nutrition*, 1955, **57**, 133–145. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

In the first experiment groups of 3 male weanling rats were given to appetite diets varying in composition, while water was given to appetite or at the rate of 4 ml. or 2 ml. per rat daily for 3 weeks; the effects on growth and organ : bodyweight ratios were studied. In the second and third experiments the effects on growth, water consumption, energy and food intake, protein utilisation, liver fat content and organ : bodyweight ratios of diets in which fat was progressively substituted for carbohydrate at each of 3 protein levels were studied; food and water were given to appetite.

When water was restricted, diets high in fat or protein or both produced larger weight losses and more fatalities than did high-carbohydrate diets. The progressive substitution of fat for carbohydrate in low-protein diets resulted in increased energy intake, increased efficiency of protein utilisation, increased growth and no change in total body sp. gr., although the protein : energy ratio was constant. The progressive substitution of fat for carbohydrate at optimum protein intake resulted in decreased efficiency of protein utilisation, reduced growth and no change in total body sp. gr. with the protein : energy ratio maintained constant. The study of organ : bodyweight ratios showed reduced thymus ratios and increased kidney ratios with increased restriction of water intake and larger thymus ratios with increased protein intake. Liver ratios were little affected by changes in water or protein intake; spleen ratios behaved like those of the thymus.

IAMPIETRO, P. F. **Fluid, sucrose and electrolyte distributions after intraperitoneal injections of sucrose solution in the rat.** *Amer. J. Physiol.*, 1955, **182**, 148–154. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Rats weighing about 200 g. received an intraperitoneal injection of 1 ml. per 100 g. bodyweight of 1·5 *M* sucrose solution. Na and Cl at once diffused into the peritoneal cavity and their concentrations in plasma fell, reaching the lowest values about 30 min. after the injection. Sucrose entered the plasma and in 15 min. reached a concentration of 35 m*M* per litre, which fell as the sucrose concentration in urine rose. Na and Cl concentrations in urine fell steeply as that of sucrose increased. There was a fall of 4·5 per cent. of bodyweight in the intracellular water at the end of 30 min. and an initial increase in extracellular water followed by a fall to below the initial level. Water diffused into the peritoneal cavity.

When distilled water or hypotonic sucrose was injected, Na and Cl diffused into the peritoneal cavity, but water diffused out. Diuresis occurred after both hypertonic and hypotonic solutions. It is suggested that hypertonic sucrose solutions may be used to produce rapid dehydration in the rat; by withdrawal of the peritoneal fluid after 2 hr., about 4 per cent. of the bodyweight as water could be removed, and another 2 per cent. was lost in the same time by diuresis.

The cells lost water with all doses of sucrose above 1 per cent. bodyweight of 0·9 *M* solution and gained water with all smaller doses.

BAXTER, J. H. and GOODMAN, H. **Renal and hepatic lipid alterations in choline deficiency : relationship to renal necrosis.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 682–687. [Lab. Metabol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Male rats were given an experimental diet containing casein 20, sucrose 56 and Crisco 19 per cent., salts and vitamins and a control diet of similar composition with 0·3 per cent. choline chloride. Groups of animals were killed daily for 7 days and the kidneys and livers were removed for estimation of moisture content, total lipid, P, choline and free and total cholesterol.

Before the onset of renal congestion and necrosis in the experimental rats, *i.e.*, during the first 4 days, there was no substantial increase in relative renal size, nor was there any increase in lipid content of the kidneys, as there was in the liver; renal and hepatic choline decreased. After the onset of renal lesions, with congestion and necrosis, there was an increase in renal size and in total lipid per kidney, but not in renal lipid concentration. It is concluded that the cause of the renal necrosis is unknown, and it is not clear whether the fatty changes are a cause or a manifestation of injury.—G. F. Garton.

SJÖVALL, J. and ÅKESSON, I. **Intestinal absorption of taurocholic acid in the rat. Intestinal absorption of cholanic acid in the rat.**

EKDAHL, P. H. and SJÖVALL, J. **Metabolism of desoxycholic acid in the rabbit. Bile acids and steroids 26, 27, 28.** *Acta physiol. scand.*, 1955, **34**, 273–278; 279–286; 287–294. [Dept. Physiol. Chem., Univ. Lund.]

26. Biosynthetic taurocholic acid, labelled with ^{14}C in the cholic acid moiety, was given by mouth to 2 rats with lymph duct cannulae and bile fistulae and to a rat with only a lymph duct cannula.

Only traces of ^{14}C activity were found in the lymph which was collected, and most of the ^{14}C activity was recovered from the bile secreted within 1 hr. of ingestion of the labelled compound.

27. In similar experiments the absorption of cholanic acid-24-^{14}C was studied; this acid was selected because it has solubility similar to that of long-chain fatty acids which are transported, via the lymphatic pathway, as triglycerides. In the intact rat about 70 per cent. of cholanic acid given by mouth was absorbed. In rats with lymph duct fistulae 3 to 7 per cent. of the ^{14}C activity was recovered in the lymph. When animals with lymph duct and bile duct fistulae were used about 10 per cent. of the ^{14}C absorbed was found in lymph and 90 per cent. in the bile.

28. Deoxycholic acid-24-^{14}C was given to rabbits with bile duct fistulae. The metabolic products excreted into the bile were examined by paper and reversed phase chromatography. Most of the deoxycholic acid was eliminated as glycodeoxycholic acid; no transformation to cholic acid occurred.—G. A. Garton.

METABOLISM OF CELLS, TISSUES, ETC.

GENERAL PHYSIOLOGY

2115

MORGAN, J. F., CAMPBELL, M. E. and MORTON, H. J. **The nutrition of animal tissues cultivated *in vitro*. 1. A survey of natural materials as supplements to synthetic medium 199.** *J. Nat. Cancer Inst.*, 1955, **16**, 557–567. [Lab. Hyg., Dept. Nat. Health Welfare, Ottawa.]

Details are given of improvements in a synthetic medium for tissue culture previously described (Abst. 733, Vol. 20). With the improved medium as base, tests were made of the effects on survival of chick embryo heart muscle of graded additions of natural materials, in order to gain information about the nature of unidentified substances required for the nutrition of tissue cells. For increase in cell survival time, chick embryo extract was by far the best, followed by whole liver extract, beef extract, horse serum, yeast extract, liver fraction L and amniotic fluid of cattle. On the other hand, if the criterion was concentration required for maximum stimulation, whole liver extract was by far the most potent, followed by yeast extract, liver fraction L, beef extract, chick embryo extract, horse serum and amniotic fluid. Maize steep liquor, malt extract, distiller's dried solubles, liver coenzyme concentrate and ascitic fluid had no significant effect. The fact that liver, yeast and embryo extract are highly active suggests that the active substances may be coenzymes. That the results for liver coenzyme concentrate do not agree with those of other workers is taken to imply that a clear distinction must be made between cell proliferation and cell survival.—W. M. Deans.

EAGLE, H. **Nutrition needs of mammalian cells in tissue culture.** *Science*, 1955, **122**, 501–504. [Lab. Infect. Dis., Nat. Microbiol. Inst., Nat. Insts. Health, U.S. Pub. Health Serv., Bethesda, Md.]

The requirements of a mouse fibroblast and a human carcinoma cell strain are compared (see Absts. 808, 834, 1625, Vol. 26). The requirements for 13 amino-acids are closely similar. Seven vitamins or their conjugates have proved to be essential for both types of cell. The essential ions are Na^+, K^+, Ca^{++}, Mg^{++} and $H_2PO_4^-$. Both cultures grew well with glucose as carbohydrate source, and almost as well with galactose, mannose and maltose. Both required some unidentified substance supplied by a small amount of serum protein.

The application of the findings is discussed.

2117

HARRIS, H. **The sulphur requirement of rat connective tissue cells.** *Brit. J. Exp. Pathol.*, 1955, **36**, 454–459. [Sir William Dunn Sch. Pathol., Oxford.]

Cysteine and cystine, alone of 19 L-amino-acids tested, restored the power to support cell multiplication which is lost by horse serum during storage. The optimum concentration was 0·001 *M* for cysteine and 0·0001 *M* for cystine. The capacity so restored was greater than that possessed by the serum when fresh, and the rate of multiplication in fresh serum could be increased by addition of these L-acids. The D-isomers appeared to be ineffective. The same effect was produced by thioglycollic or dithioglycollic acid or by sodium

sulphite, but not by methionine, methyl-S-cysteine, cystathionine or glutathione.

LUNDSGAARD, E. Leverens rolle for den samlede organismes stofskifte. [**Role of the liver in the metabolism of the whole organism.**] *Nord. Vet.-Med.*, 1955, **7**, 869–891.

Oxidative metabolism in the liver is of such a magnitude that it accounts for from 20 to 25 per cent. of the total oxygen consumption of the resting organism in which the liver constitutes only 2·5 to 3 per cent. of weight. Alcohol, glycerol and amino-acids are not primarily oxidised by tissues other than liver, but all are partly oxidised in the liver and their products are further oxidised to CO_2 and water in extra-hepatic tissues. The procedure is not quite the same with fat and fatty acids. These can be completely oxidised in any tissue. In the liver they undergo β-oxidation to acetic acid, and 2 molecules of acetic acid may be condensed to form ketones. The fact that the liver that is actively producing ketones is also producing more than the normal output of CO_2 argues against the theory that the cause of ketone production is blocking of the tricarboxylic acid cycle. Instead it has been suggested that, in the normal liver, concurrently with partial oxidation to acetic acid, fresh synthesis of fatty acids from acetic acid goes on and it is this re-synthesis that is blocked when ketones are produced. Neither theory is satisfactory. A change in the rate of breakdown of fat, with excess production of acetic acid, excess condensation to ketones and displacement of higher fatty acids in extra-hepatic tissues is more probable. If that is so, then partial oxidation of fat in liver is not an obligatory stage in its breakdown to yield energy as is partial oxidation of ethyl alcohol, glycerol and amino-acids.

For part 1 see Abst. 4947, Vol. 24.

In washed rabbit red cells the acceleration of disappearance of methaemoglobin in the presence of glucose, fructose or glucose plus methylene blue depended on the time which elapsed between warming the cell suspension to 37° C. and adding the substrate : the later the addition, the less the effect. With lactate or formaldehyde the acceleration was independent of the time of addition.

It is concluded that the decline in ability of the cells to utilise glucose or fructose is a result of gradual dissipation of adenosine triphosphate in general cell metabolism and failure of its re-synthesis.—D. Duncan.

2121

WILSON, T. H. and VINCENT, T. N. **Absorption of sugars *in vitro* by the intestine of the golden hamster.** *J. Biol. Chem.*, 1955, **216**, 851–866. [Dept. Biochem., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

Segments of small intestine from hamsters were made into sacs with the serosal surface inside and were filled with bicarbonate saline solution and suspended in similar solutions containing the carbohydrates to be studied at the 1 per cent. level. They were incubated for 1 hr. at 37° C. under oxygen or nitrogen with 5 per cent. CO_2. The final volume of fluid inside the sac was estimated by weighing.

When the intestinal sac was suspended in fructose solution, glucose appeared on the serosal side. Fructose did not cross the wall against a concentration gradient ; its final concentration was the same on both sides, but the glucose concentration on the serosal side was high. The amount of fructose converted to glucose per mg. dry weight of tissue was constant, at about 1·7 to 2·3 μg. per hr., and the movement of free fructose was proportional to the concentration on the mucosal side. Fructose placed on the serosal side appeared on the mucosal side at much the same rate as sorbose or xylose. In anaerobic conditions the movement of fructose from mucosal to serosal side was about trebled, but there was no conversion to glucose.

Galactose was transported against a concentration gradient in the absence of glucose. Utilisation and rate of transport were similar to those of glucose. No evidence for conversion to glucose was found. Transport against a gradient did not occur anaerobically. 3-Methylglucose was transported aerobically against a gradient at about half the rate of glucose and galactose. There was no evidence that it was utilised or converted to glucose.

Fructose, mannose, sorbose, xylose, arabinose and ribose were not transported against a gradient. Glucose did not facilitate their transport. Absorption of glucose or galactose aerobically was 5 or 10 times as fast as that of most other sugars, but transport from serosal to mucosal side was much less.

Sucrose, maltose and lactose placed on the mucosal side of the intestine were hydrolysed at

different rates, lactose slowest. When sucrose was hydrolysed to glucose and fructose, only glucose appeared on the serosal side in appreciable quantity. Little lactose was hydrolysed ; similar quantities of glucose and galactose were found on the mucosal side, but more galactose on the serosal side. With soluble starch, only glucose appeared on the serosal side.—D. Duncan.

WHITNEY, J. E. and ROBERTS, S. (with BEAVER, E. L.). **Influence of previous diet on hepatic glycogenesis and lipogenesis.** *Amer. J. Physiol.*, 1955, **181,** 446–450. [Dept. Physiol. Chem., Sch. Med., Univ. California Med. Centre, Los Angeles.]

Liver slices were obtained from adult male rats which had been fed for 2 to 3 months on either a stock diet or a diet high in fat or carbohydrate and killed 1 hr. or 24 hr. after the last feed. The stock diet provided about half its energy as carbohydrate and 15 per cent. as fat ; the other 2 diets had 85 per cent. of their energy as maize oil or glucose. The liver slices were minced and incubated at 37° C. for 6 hr. in a rat serum medium containing acetate-^{14}C, and the incorporation of ^{14}C into fatty acids, cholesterol, glucose and glycogen was studied.

The high-fat diet caused less incorporation of the methyl carbon of acetate into liver glycogen and fatty acids in the tissue of non-fasting animals as compared with values obtained from liver tissue of animals fed on the stock or high-carbohydrate diet ; in contrast, liver cholesterol contained more ^{14}C. Other evidence presented suggests that these findings are a reflection of depressed glycogen and fatty acid formation which accompany increased formation of cholesterol in fat-adapted animals.

G. A. Garton.

2124

WHITNEY, J. E., ROBERTS, S. and BEAVER, E. L. **Influence of previous diet on hepatic utilization of glucose *in vitro*.** *Amer. J. Physiol.*, 1955, **182,** 51–53. [Dept. Physiol. Chem., Sch. Med., Univ. California Med. Centre, Los Angeles.]

Adult rats were killed after being for from 2 to 3 months on a synthetic diet with 85 per cent. of its energy derived from either fat or carbohydrate. Some had fasted for 24 or 48 hr. before death. Carbon dioxide production and formation of glycogen in liver tissue were studied during incubation with buffer solution containing ^{14}C-glucose. In liver from rats which had not fasted production of CO_2 was less in the fat than in the carbohydrate group ; the effects of fasting did not differ in the groups. Measurements of radio-activity showed that production of CO_2 and glycogen from glucose also were less in the fat than in the carbohydrate group ; the difference was detectable in rats which had fasted for 24 or 48 hr.

It is concluded that the liver tissue in the group given fat may oxidise preferentially some compound other than the added glucose ; measurements of R.Q. in this study support the hypothesis (see Abst. 1473, Vol. 14) that this may be fat, the main constituent of the preceding diet.

PARK, C. R., BORNSTEIN, J. and POST, R. L. **Effect of insulin on free glucose content of rat diaphragm *in vitro*.** *Amer. J. Physiol.*, 1955, **182,** 12–16. [Dept. Physiol., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Diaphragms were obtained from young rats fasted for 18 to 20 hr. Insulin was found to accelerate the uptake of glucose from solutions of 500 mg. glucose per 100 ml. ; 97 per cent. of that taken up was accounted for by phosphorylation with insulin, and 95 per cent. without. With 2000 mg. glucose per 100 ml., insulin again accelerated glucose uptake, but now 66 per cent. of the increase was accounted for by increase in the free glucose content of the tissue. With 200 mg. glucose per 100 ml. medium, insulin increased free glucose and not phosphorylation at 12° C., when the hexokinase system was inhibited. Thus increased uptake of glucose in the presence of insulin is independent of phosphorylation. Studies with ^{14}C-labelled glucose showed that the increased glucose content of the tissue was indeed due to uptake and not to new formation of glucose *in situ*.

SIMPSON, M. V. and MCLEAN, J. R. **The incorporation of labeled amino acids into the cytoplasmic particles of rat muscle.** *Biochim. biophys. Acta*, 1955, **18,** 573–575. [Dept. Biochem., Yale Univ., New Haven, Conn.]

Male rats were given intravenous injections of 3 mg. DL-leucine-1-^{14}C. After 2, 3, 5, 10, 30, 90 or 180 min. animals were killed and samples of skeletal muscle and liver were removed for fractionation into mitochondria, microsomes and other particulate fractions by differential centrifuging of homogenates. The leucine content of the protein of each fraction was estimated microbiologically and was found to be about 10 per cent. of the weight of protein. When the incorporation of labelled leucine was measured the microsomal fraction was the most active and the mitochondrial fraction the least active, having less than 25 per cent. of the uptake of the microsomal fraction; the difference was greatest at short time intervals. In muscle the rate of incorporation into the mitochondrial fraction was not appreciably lower than into the microsomes; after 5 min. or less the incorporation into the mitochondrial fraction of muscle was somewhat higher than in the microsomal fraction. Similar results were obtained when phenylalanine-3-^{14}C was substituted for leucine-1-^{14}C.—G. F. Garton.

LAIRD, A. K., BARTON, A. D. and NYGAARD, O. **Synthesis of protein and ribonucleic acid in rat liver during refeeding after starvation.** *Exp. Cell. Res.*, 1955, **9,** 523–540. [McArdle Mem. Lab., Univ. Wisconsin, Madison.]

Male albino rats were starved for 6 days and then permitted free access to a normal diet. Groups of 4 rats were killed at intervals up to the twelfth day of re-feeding. An injection of glycine-2-^{14}C and inorganic phosphate containing ^{32}P was given 3 hr. before death. In starved rats the livers lost about 50 per cent. of weight and of their protein and ribonucleic acid content. During the first day of re-feeding there was an immediate and rapid increase in weight of the liver, but the rise in protein and ribonucleic acid content was small. Ribonucleic acid increased first in the mitochondria, and the content of all fractions was restored to normal in 7 days. The protein and ribonucleic acid content of the nuclear fraction fluctuated during re-feeding, but the amount in the cytoplasm increased fairly steadily. The ribonucleic acid content of the liver increased only during periods of active change in the protein content of the nuclear fraction. It is suggested that in rat liver during recovery from starvation protein is synthesised by two processes, one an intermittent production of protein by the nucleus, accompanied by production of ribonucleic acid, the other a steady production of protein in the cytoplasm.

ROSE, G. and SHAPIRO, B. **The synthesis of fatty acids and glycogen by adipose tissue *in vitro*.** *Biochim. biophys. Acta*, 1955, **18,** 504–510. [Dept. Biochem., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.] French and German summaries.

Mesenteric adipose tissue was obtained from male rats which had been fasted for 5 to 6 days and then divided into 2 groups, one of which continued to fast for 24 hr., while the other was fed. The tissue was then incubated at 37° C. for 3·5 hr. with uniformly labelled ^{14}C-glucose, 2-^{14}C-pyruvate or 1-^{14}C-acetate in a medium consisting of 5 per cent. serum albumin in Krebs Ringer phosphate buffer. Long-chain fatty acids and glycogen were then isolated for measurement of their radio-activity.

Tissue from fed rats formed much fatty acid from pyruvate and glucose and less from acetate; tissue from starved animals showed a depression of $\frac{1}{15}$ to $\frac{1}{16}$ of the values obtained from all precursors in tissue from fed animals. The addition of glucose partly restored fatty acid synthesis from acetate in the starved tissue, but was without effect on synthesis from pyruvate or glucose; the addition of succinate or α-ketoglutarate had no effect.

The incorporation of ^{14}C-glucose into glycogen was not affected by starvation.—G. A. Garton.

TULPULE, P. G. and WILLIAMS, J. N. (Jr.) **Study of the role of essential fatty acids in liver metabolism.** *J. Biol. Chem.*, 1955, **217**, 229–234. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of rats were fed for 6 weeks on a basal diet with and without the addition of methyl linoleate or vitamin B_6. Some groups were fed to appetite the whole time, others received restricted amounts of food for part of the experiment. The livers were removed and homogenised for assay of the activity of enzyme systems.

Liver tissue from animals without linoleate showed an increased titre of the antimycin-A-sensitive substance and of cytochrome oxidase ; vitamin B_6 appeared to be necessary for the maintenance of the enzymes affected by deficiency of essential fatty acids. Linoleate deficiency was accompanied by a fall in the ratio of phosphate esterified to oxygen consumed for the oxidation of reduced diphosphopyridine nucleotide and cytochrome *c*.

It is considered that the main site of action of essential fatty acids is in the phosphate esterification system, coupled with the oxidation of reduced cytochrome *c*.—G. A. Garton.

FELLER, D. D. and HUFF, R. L. **Lipide synthesis by arterial and liver tissue obtained from cholesterol - fed and cholesterol - alcohol - fed rabbits.** *Amer. J. Physiol.*, 1955, **182**, 237–242. [Radioisotope Unit, Veterans Admin. Hosp., Seattle, Wash.]

Liver slices and strips of aorta were obtained from normal rabbits and others which had received diets with added cholesterol, with or without ethanol in their drinking water. Analysis of serum and tissues showed that alcohol did not affect the high blood cholesterol or the increased lipid content of tissues found when cholesterol alone was given. Strips of sclerotic aorta, when incubated with acetate labelled with ^{14}C, incorporated the same amount of ^{14}C into fatty acids, unsaponifiable matter and CO_2 as did normal aortic tissue. Similar experiments with liver slices showed that formation of fatty acid and cholesterol from acetate was reduced in animals given cholesterol ; no effect on the oxidation of acetate was found. The role of dietary cholesterol in the regulation of aortic and hepatic lipid synthesis is discussed.—G. A. Garton.

HILL, R., BAUMAN, J. W. and CHAIKOFF, I. L. **Dietary repair of defective lipogenesis and cholesterogenesis (from C^{14}-acetate) in the liver of the hypophysectomized rat.** *Endocrinology*, 1955, **57**, 316–321. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Liver slices from normal and hypophysectomised rats were incubated with acetate-1-^{14}C and the extent of incorporation of ^{14}C into fatty acids and cholesterol was studied. Slices from hypophysectomised animals which had been fed on a diet containing 25 per cent. sucrose as the only source of carbohydrate showed a greatly reduced capacity for converting acetate into fatty acids and cholesterol. This capacity was normal when a diet containing 60 per cent. sucrose or starch was given to hypophysectomised rats.

It was concluded that the maintenance of normal liver synthesis of fatty acids and cholesterol is independent of anterior pituitary hormones, as long as an abundance of glucose is provided by the diet.—G. A. Garton.

MIGICOVSKY, B. B. and WOOD, J. D. **Effect of starvation on cholesterol biosynthesis *in vitro*.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 858–866. [Div. Chem., Sci. Serv., Canada Dept. Agric., Ottawa.]

Liver homogenates from normal rats and from rats fasted for 48 hr. were separated into 3 fractions, coarse and finer particulate matter and " clear supernate ", by centrifuging at up to 140,000 *g*. The liver preparations were incubated with adenosine triphosphate, dipyridine nucleotide and acetate-1-^{14}C at *p*H 7·2.

Incorporation of acetate-1-^{14}C into cholesterol could be demonstrated in normal rat liver preparations when either particulate residue was incubated with clear supernate. Liver preparations from fasted rats showed no such synthetic activity, although incubation of clear supernate from liver homogenate of starved rats with normal particles appeared to give some activity. Degradation of cholesterol occurred with the coarse particles from both normal and starved rats.—A. K. Lough.

GARTON, G. A. **The metabolism of phospholipids in the lactating mammary gland of the rabbit.** *Biochem. J.*, 1955, **61**, 402–406. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The specific radio-activity of the phospholipins of mammary gland tissue and liver from 2 lactating rabbits injected intravenously with ^{32}P-phosphate was on the average 12·1 and 9·0 per cent. of the corresponding value for glycerophosphate. In the one rabbit which was milked the specific radio-activity of phospholipin P from mammary gland, milk and plasma was 262, 107 and 99, indicating that phospholipin was formed in the mammary gland.

In 4 lactating rabbits injected with plasma containing labelled phospholipins the specific radio-activities of phospholipin, glycerophosphate and inorganic phosphate decreased in that order in the mammary gland. The apparent breakdown of phospholipin was calculated to be 20 per cent. in 2 hr. The milk was not radio-active.

2139

GEYER, R. P., SCHOLTZ, K. J. and BOWIE, E. J. **Influence of calcium on potassium concentration in rat liver *in vitro*.** *Amer. J. Physiol.*, 1955, **182,** 487–492. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Liver slices from fasted rats and from rats fed on a commercial stock diet were used to study the effect on liver K of varying Ca content of the suspending medium, the effect of Ca on the loss of liver K in K-free media and on the subsequent recovery of K in K-containing media in anaerobic and aerobic incubation, and the effect of replacement of Ca by Ba and Sr in the medium.

K was gained by liver slices from fed rats in aerobic or anaerobic conditions provided that sufficient Ca was present in the medium, and when such K had been gained aerobic conditions were unnecessary for its maintenance. Liver slices from fed rats regained about the normal K content from low-K media provided Ca was present ; slices from fasted rats gained about 80 per cent. of the normal K content in the presence of Ca. When such slices were placed in N they rapidly lost K. Ba could replace Ca, but Sr was less effective.

G. F. Garton.

DALLEMAGNE, M. J., BODSON, P. and FABRY, C. Le calcium échangeable de la substance minérale de l'os étudié à l'aide de ^{45}Ca. [**Exchangeable calcium of the mineral substance of bone studied with ^{45}Ca.**] *Biochim. biophys. Acta*, 1955, **18,** 394–406. [Inst. Thérap. Exp., Univ. Liège.] English and German summaries.

Bone mineral was treated with solutions containing different concentrations of $^{45}CaCl_2$, allowing Ca of the bone mineral to exchange with ^{45}Ca. The solid phase containing exchanged ^{45}Ca was extracted with dilute HCl, and total Ca, ^{45}Ca and total P were estimated in each extract. The first extracts contained principally the " excess " Ca, and the quantity of Ca exchanged on treating the bone salt with dilute $CaCl_2$ was similar to the quantity of " excess " Ca. Greater quantities of Ca were exchanged when the concentration of $CaCl_2$ was increased.—R. Hill.

2143

GREENBERG, D. M. and SASSENRATH, E. N. **Tumor-host relationships. 2. Tolerance to injection of amino acids.** *Cancer Res.*, 1955, **15,** 620–625. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

For part 1 see Abst. 2418, Vol. 25.

Tissues were taken as before from normal rats and others used 7 to 9 days after implantation of Walker carcinoma 256. The rats were first fasted for 16 to 18 hr., then given an intraperitoneal injection of a massive dose of amino-acid, 0·56 g. per kg. bodyweight. They were killed 1¼ to 15 hr. later, and free amino-acids were estimated in liver, muscle and plasma.

Tumour-bearing rats showed lower peak values in all tissues for glycine after glycine injection, and after injection of serine there was an indication that glycine was utilised more readily by rats with tumours, since there was no increase in liver or muscle glycine values. There was less threonine dehydrase activity in liver tissue from tumour-bearing rats, but no change in serine dehydrase.

KLAVINS, J. V., KINNEY, T. D. and KAUFMAN, N. **Hepatic nodules resembling tumors in rats after administration and withdrawal of ethionine.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 540–543. [Dept. Pathol., Cleveland City Hosp., Ohio.]

Five groups of rats were given a synthetic diet with vitamins. Two, of 28 and 14 animals, were controls for 2 groups of 28 and 23 which received ethionine in the diet at the rate of 0·5 per cent. for 28 and 63 days. The fifth group of 8 rats had ethionine for the first 28 days and the diet without addition for the next 35.

No control animal showed lesions. In the rats given ethionine for a month changes like those already reported occurred, but nodule formation was not seen; after 2 months nodules were found in 16 of the 23 animals. In 3 they resembled hepatomas, in 10 cholangiomas and in the 3 others both types occurred. In the fifth group, given ethionine for part of the time, nodules resembling cholangiomas were found in 5 of the 8 rats, a proportion the same as in group 4, in which the animals had ethionine all the time.

MORTON, N. E. **The inheritance of human birth weight.** *Ann. Human Genetics*, 1955, **20**, 125–134. [Dept. Genetics, Univ. Wisconsin.]

Data on birthweights were abstracted from records collected in Hiroshima and Nagasaki between 1948 and 1952. From each family included in the study, weights of 2 babies were used and were classified as twins of like or of unlike sex, adjacent sibs, sibs with one intervening sib, sibs with 2 intervening sibs, paternal half-sibs, maternal half-sibs, or adjacent sibs whose parents were first cousins.

The correlation of birthweights within pairs of maternal half-sibs, 0·58, was much greater than that for pairs of paternal half-sibs, 0·10; the latter correlation was non-significant. This suggests that maternal, not purely genetic, effects decide the birthweight.

The within pair correlations for like-sexed and unlike-sexed twins were similar, 0·56 and 0·66, although most of the like-sexed twins would have been monozygous. This is again evidence that similarity of birthweight is due more to common uterine environment than to genetic relationship.

The within pair correlation of birthweights was 0·52 for adjacent sibs, 0·42 where one sib intervened and 0·36 where 2 sibs intervened. The effect is attributed in part to maternal age and parity, and confirms that maternal effects on birthweight are not entirely determined by the genotype of the mother.

A combined analysis of the data for half-sibs, twins, and full sibs produced consistent results. Significant components of the variance of birthweight were found, corresponding to permanent and temporary maternal factors and to random environmental factors, but there was no significant genetic component.

Inbreeding would be expected to reduce the variation between sibs if birthweight were highly heritable. There was a slight drop in mean birthweight with increased inbreeding, but no effect on the variance, and the evidence is therefore consistent with the hypothesis that the genotype of the foetus accounts for only a small part of the variance of human birthweight.—I. McDonald.

SCRAGG, R. F. R. **Birth weight, prematurity and growth rate to thirty months of the New Guinea native child.** *Med. J. Austral.*, 1955, i, 128–132. [Port Moresby.]

Data from Rabaul and Kavieng are regarded as representative of New Guinea. The mean birthweights for 393 Kavieng babies were 5·84 lb. for males and 5·87 for females; for 1107 Rabaul babies 6·64 and 6·34 lb. For English infants the mean birthweight for both sexes is given as 7·46 lb. Birthweights of Rabaul babies were significantly higher than those from Kavieng, probably because of the more constant food supplies of Rabaul natives, who have an unlimited supply of bananas; Kavieng natives eat few bananas and have as their staple food sago, which takes much more preparation. Kavieng babies regained their birthweight sooner than Rabaul babies. There was no increase in the weight of infants born to Kavieng women who were fed on National Medical Research Council balanced diets for 1 or 2 months before delivery.

The recognised international standard for prematurity is 5·50 lb., by which the percentage premature would be for Rabaul babies 15·01, and for Kavieng babies 30·05. That for English babies is 5·62. It is obvious, therefore, that the standard could not apply to New Guinea babies, so many of whom were underweight though mature. From frequency distribution of birthweights, survival at low birthweights, and mean birthweights, a new standard of 4·50 lb. was calculated for New Guinea infants. By it, 13 per cent. of Kavieng babies and 5·2 per cent. of Rabaul babies were premature.

Rate of weight increase was studied in 651 Kavieng babies, all but 12 of whom were entirely breast fed on demand. The rate of weight increase during the first 3 months exceeded that of English babies, but from 4 to 12 months it was less, probably owing to disease rather than to unsatisfactory diet, since after illness weight was rapidly regained. From 12 to 30 months the rate nearly equalled that of English babies, but always at a lower level.

Mean weights, graduated for age from 3 weeks to 2 years 6 months, with standard deviations, are presented as a guide to the normal development of New Guinea children.—M. H. Pierce.

2151

MILLIS, J. **The effect of economic background on body size of Chinese infants in the first year.** *J. Trop. Pediat.*, 1955, **1,** 156–160. [Dept. Social Med., Univ. Malaya, Singapore.]

See also Abst. 909, Vol. 24.

At birth the mean bodyweight and length of male and female infants of Chinese mothers of the upper and middle economic group were significantly greater than those of infants of the lower economic group. In both groups the boys were significantly larger than the girls. The advantage in weight persisted, and at the end of the first year the male infants had increased in weight more rapidly than the female, and the infants of the better off more rapidly than those of the poorer families; the differences were significant. The differences in weight at 1 year were not wholly accounted for by the differences in birthweight.—L. Wills.

2152

FALKNER, F. **Measurement of somatic growth and development in children.** *Courrier*, 1954, **4,** 169–181. [Inst. Child Health, Hosp. Sick Child., Gt. Ormond St., London.] French and Spanish summaries.

The longitudinal studies of growth that have been begun at the Institute of Child Health in London and the sister institute in Paris are described. A third study has just begun in Zürich and a fourth is to begin in Stockholm. The superficial measures to be recorded are: standing or lying height and weight, sitting height and occiput-coccyx distance, hip width and chest circumference; subcutaneous tissue at 4 sites; bone growth as distance between fixed points; head circumference and bi-acromial breadth. Technique requires training, especially X-ray technique for measurement of tissues. Subjects will be somatotyped, and maturity of skeleton and sexual development will be estimated. Family, social and health histories will be built up. Observations will be recorded at 4 weeks $\pm$ 2 days of age and subsequently at 13, 26, 39, 52 and 78 weeks and 2 years and then yearly to maturity. A total of 400 subjects is aimed at. In course of time it is hoped to make racial comparisons and to extend the studies to include mental and psychomotor development.—I. Leitch.

2153

HAMMOND, W. H. **Body measurements of pre-school children.** *Brit. J. Prev. Social Med.*, 1955, **9,** 152–158.

In connection with a national survey, 214 boys and 237 girls born in different areas and social groups in Leeds between September and December 1949 were weighed and standing height, sitting height and leg length and several breadth and girth measurements were ascertained by 2 workers, using techniques described, at 1 year; thereafter only those born in December 1949 were followed up and measured again by the author at yearly intervals up to 5 years of age. The means and mean increments in kg. and cm. and their standard deviations are tabulated and compared with those of Low for children of Aberdeen in the twenties (Abst. 713, Vol. 23).

The Leeds children were taller and heavier than the Scottish children, the 4-year-olds being nearly equal to Low's 5-year-olds; this difference may be partly regional but is thought to be more probably due to secular change. Variability of measurements was slightly less in the Leeds group. When the data for Leeds children of 5 were adjusted to age 5 years 6 months, they were found to be somewhat above those for council school children of that age from poor areas (Abst. 2186, Vol. 24). When log weight was plotted against height, points for the council school children and Leeds pre-school children of 3, 4 and 5, but not for the younger children, fell on the same straight line; the points for the Scottish children fell below the line, but this is probably because they were measured lying down. For chest girth relative to weight a single curve sufficed for all 3 groups. For interacromial and intertrochanteric breadth relative to height, the values for the 2 English groups were again consistent; the Scottish children were somewhat broader for a given height. It is considered that if weight and height are known, other mean measurements can be predicted from these graphs with reasonable accuracy. A table of correlations between height and other lengths and breadths and between weight and girths for different age groups, based on the present sample and those previously studied by the author, shows little change with age.

ROUTIL, R. Grössen-Gewichtstabellen als Kriterien individueller Entwicklungsstudien an Kärntner Schulkindern. **[Tables of height and weight as criteria in studies of the development of individual Carinthian school-children.]** *Öst. Ztschr. Kinderheilk.*, 1955, **11,** 302 – 324. [Anthropol. Abt., Naturhist. Museum, Vienna.]

In continuation of previous studies (Abst. 912, Vol. 24), analysis was made of the recorded data for height and weight for 63,167 schoolchildren aged from 6 to 15 years in Klagenfurt and 4 other regions in Carinthia. Graphic methods of representing the results are discussed. Development was more rapid in the town of Klagenfurt than in the rural districts of the province.—E. M. Hume.

2156

MEREDITH, H. V. **A longitudinal study of change in size and form of the lower limbs on North American white schoolboys.** *Growth*, 1955, **19,** 89–106. [State Univ. Iowa, Iowa City.]

A study of 70 boys. Lower limb length is stature minus stem length, girth is maximum circumference and the index is ratio of girth to length $\times$ 100. Mean increments in length for the years 5 to 7, 7 to 9 and 9 to 11 were, in cm., 8·0, 7·1 and 6·3. Girth and index also are tabulated and graphed.—I. Leitch.

2157

HEWITT, D., WESTROPP, C. K. and ACHESON, R. M. **Oxford Child Health Survey: effect of childish ailments on skeletal development.** *Brit. J. Prev. Social Med.*, 1955, **9,** 179–186. [Social Med. Unit, Univ. Oxford.]

For previous results of the Oxford Child Health Survey see Absts. 719, 3400, Vol. 23; 4970, Vol. 24; 2618, 3952, Vol. 25.

The effect of illnesses such as exanthemata, lower and upper respiratory infections, skin diseases and other infections except head colds was studied on growth (height) and skeletal maturation during the second to fifth years of life in some 650 children. X-ray studies of hands and knees were made for the appearance of transverse striations (Harris's lines) associated with arrest of growth. Skeletal maturation was assessed by the method of Acheson (Abst. 2618, Vol. 25).

Rate of growth was slightly reduced by illness, the reduction depending on the severity of the infection, and boys were slightly more affected than girls. It is calculated that a child who escaped illness between the ages of 1 and 5 years would have been on the average 1 in. taller than one who had had a severe illness each year. None of the diagnosed illnesses had any particular growth-retarding effect. Illness had no definite effect on skeletal maturity, but there were indications that maturation of the carpals was slightly more susceptible to interruption by illness than that of the epiphyses of the hand, wrist or knee. The incidence of new Harris's lines was much more affected by illness than either growth or skeletal maturation, and the effect was greater in exanthemata, particularly measles, and lower respiratory infections.—J. S. Thomson.

2158

KEEN, J. A. **Times of appearance of the epiphyseal centres in the Bantu and Indian population groups.** *S. African J. Lab. Clin. Med.*, 1955, **1**, 80–93. [Dept. Anat., Univ. Natal.]

A study was made of 2219 X-ray photographs of upper and lower limbs taken in a Durban hospital in 12 months, mostly in the casualty department. The patients were grouped as Bantu or Asiatic, by sex, and by age from birth to 22 years. The stages of epiphyseal union were divided into "entirely separate", "partially united" and "united", the last only when the "epiphyseal scar" was absent.

The appearance of bony centres in the epiphyses and in carpal and tarsal bones, and epiphyseal fusion, almost always occurred earlier in girls than in boys. The mean age for carpal ossification centres was almost exactly 9 years in 942 girls and 10 years 9 months in 1633 boys, a highly significant difference. There was no significant difference in times of appearance of ossification centres and of fusion of epiphyses between Bantu and Indian groups, or between these groups and European children studied elsewhere. There was little difference in ossification times between the 2 sides of the body.—D. Duncan.

2159

VERDUN, M. and DE TAILLE, J. Canon des proportions corporelles linéaires et volumétriques du Français moyen. **[Standards for linear and volumetric body proportions for the average Frenchman.]** *Presse méd.*, 1955, **63**, 1644–1648. [Centre Études Scientif. de l'Homme, Paris.]

Mean values are given, with an explanatory diagram, for 33 linear body measurements obtained by a method, claimed to be new and accurate, which is described elsewhere (Pende, *Traité de médecine biotypologique*, O. Doin, Paris, 1955, chapter on anthropometrical methods) from 282 French soldiers, mean age 21 years, mostly rural working-class, as well as means and standard deviations for height, weight, chest circumference and some derived ratios and indices. Measurements should be made with the subject lying relaxed, and should be related to some overall measurement, *e.g.*, length of thigh as a percentage of stature. Reference is made to Pignet's index and one or two other simple means of picking out weaklings, but the rest of the discussion deals only with establishment of racial or constitutional type.

W. M. Deans.

2160

LOWE, C. R. and GIBSON, J. R. **Changes in body weight associated with age and marital status.** *Brit. Med. J.*, 1955, ii, 1006–1008. [Dept. Social Med., Univ. Birmingham.]

An investigation into the age : weight relation of men and women and the effect of marriage and childbearing on weight of women is based on data between 1945 and 1954, supplied by 2 large Birmingham firms.

There was very little variation in weight of men with age, or with marital status. The mean weight of women increased by about 3 lb. every 5 years. At corresponding ages, married women were considerably heavier than single women, but married women with children were only a little heavier than those without children.

A. W. Boyne.

2161

HOHLS, H. W. Bemerkungen zu der Arbeit von H. Møllgaard: Analyse des Wachstums mittels Differentialgleichungen der Partialprozesse des synthetischen Stoffwechsels. **[Remarks on the paper by H. Møllgaard: Analysis of growth by differential equations of partial processes of synthetic metabolism.]** *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 257–264. [Bundesforschungsanst. Kleintierzucht, Celle.]

See Abst. 5421, Vol. 25.

The limits of the conditions under which Møllgaard's equations can be applied in practice are discussed. It is argued that growth in weight under ordinary experimental conditions, say with groups of 20 chicks, cannot be expressed as a series of discrete equations, since the 20 chicks are not growing at identical rates. The equations can be applied only to parts of the growth curve that are straight lines and do not apply to early growth; and, further, the Møllgaard constants may be identical when the weight curves are not, and different when the weight curves are parallel but the ages of the animals are different.

I. Leitch.

2162

MØLLGAARD, H. Bemerkungen zu den Ausführungen des Herrn Dr. H.-W. Hohls hinsichtlich meiner Arbeit über rationelle Wachstumsmessungen. [**Remarks on the views of H.-W. Hohls on my paper on the rational measurement of growth.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 264–269. [Physiol. Lab., Landw. Versuchsstat., Copenhagen.]

Hohl's arguments (see above Abst.) about growth in terms of bodyweight are valid because gross increase in bodyweight, with changes in deposition of fat and water, does not represent true growth. Hence the use (Abst. 5421, Vol. 25) of metabolism data for N, Ca and P.

To extend the study, measurements have now been made on pigs from birth to the 70th day by Berge and Indrebø in Norway and by Møllgaard in Denmark. These show that for protein the rate of increase may be expressed as 2 straight lines. For Danish boars the turning point is between day 22 and day 27 ; for Danish sows about halfway between ; Norwegian boars show a turning point at the 38th day. From the 70th day a third straight line continues to the 180th day for sows and castrates ; boars have a third small inflection at 108 days.

The theory of the whole process, in terms of structural growth and cell subdivision, as derived from these metabolism studies and cytological studies is briefly summarised (see Abst. 847, Vol. 26).—I. Leitch.

REPRODUCTION AND LACTATION: MAMMALS

2165

ROMNEY, S. L., REID, D. E., METCALFE, J. and BURWELL, C. S. **Oxygen utilization by the human fetus in utero.** *Amer. J. Obstet. Gynecol.*, 1955, **70,** 791–797 (with discussion 797–799). [Boston Lying-in-Hosp., Mass.]

From estimates of blood flow through the uterus by the nitrous oxide technique, and the difference in oxygen tension between uterine artery and vein compared with the difference in oxygen tension between umbilical vein and artery, it appears that the rate of blood flow in the placenta must be about the same as in the uterus, 500 ml. per min., and that the oxygen consumption of the foetus at term, at 5 c.c. oxygen per kg. per min., is comparable with that of the mother. In a twin pregnancy the rate of blood flow in the uterus was twice that in single pregnancies.—I. Leitch.

2166

PAYNE, H. W. and LATOUR, J. P. A. **Quantitative estimations of endometrial glycogen, using the anthrone method.** *J. Clin. Endocrinol.*, 1955, **15,** 1106–1115. [Dept. Gynaecol. Pathol., Royal Victoria Hosp., Montreal.]

Glycogen was estimated in 90 specimens of endometrium obtained by curettage from women attending gynaecological and sterility clinics and from uteri removed at operation.

With the onset of menstrual bleeding the mean glycogen content fell sharply from about 0·9 to under 0·2 g. per cent. by the fourth day. It remained at about this level until the 14th day, when it rose steeply to about 1·4 on the 17th day, thereafter falling to about 0·4 on the 21st day and rising slowly again until the end of the cycle. The older group of women differed from the average in showing no sharp decrease of glycogen concentration after the 18th day.

It is thought that the fall after the 17th day is due to contribution in both energy and nutrients to the endometrial secretion at the time when the morula normally enters the uterus and secretion is greatest. The use of glycogen by the endometrium of older women may lead to deficient secretion and to infertility.—F. Hytten.

WRIGHT, D. E. **Fat in liver and kidneys of pregnant sheep at different levels of nutrition and during starvation.** *Brit. J. Nutrition*, 1955, **9,** 279–286. [Dept. Physiol., Med. Sch., Newcastle upon Tyne 1.]

Liver and kidney tissue obtained from 44 pregnant ewes was examined histologically. The animals had been maintained by Ferguson (Abst. 978, Vol. 25) on a high or low plane of nutrition during pregnancy ; some animals were killed after having been starved for 1 to 6 days.

Liver fat was not greatly increased by the high-plane diet, except when the ewes had been starved ; fatty infiltration of the liver was found in ewes given the low-plane diet, especially after starvation. Kidney sections, though they contained less fat, varied in the same way as liver sections. In

general these findings paralleled the chemical analyses of Ferguson (Abst. 979, Vol. 25).

ALEXANDER, D. P., ANDREWS, R. D., HUGGETT, A. ST. G., NIXON, D. A. and WIDDAS, W. F. **The placental transfer of sugars in the sheep: studies with radioactive sugar.** *J. Physiol.*, 1955, **129,** 352–366. [Dept. Physiol., St. Mary's Hosp. Med. Sch., Univ. London.]

^{14}C-Glucose injected into pregnant ewes gave rise to both ^{14}C-glucose and ^{14}C-fructose in the foetal blood. Foetal hyperglycaemia caused transfer of ^{14}C-glucose from foetal to maternal blood. The absolute transfer of glucose from ewe to foetus was greater than 70 mg. per min., but the net transfer was less than would be expected from simple diffusion.—A. T. Phillipson.

2170

ALEXANDER, D. P., HUGGETT, A. ST. G., NIXON, D. A. and WIDDAS, W. F. **The placental transfer of sugars in the sheep : the influence of concentration gradient upon the rates of hexose formation as shown in umbilical perfusion of the placenta.** *J. Physiol.*, 1955, **129,** 367–383. [Dept. Physiol., St. Mary's Hosp. Med. Sch., Univ. London.]

The sheep's placenta was perfused to study the rate at which it makes fructose. The results suggest that production of fructose is constant and independent of the concentrations of glucose on either side of the placenta. Transfer of glucose across such perfused placentae agreed with the rate of transfer of ^{14}C-glucose in ewes with the placenta *in situ*.—A. T. Phillipson.

2171

DAVIES, J. **Permeability of the rabbit placenta to glucose and fructose.** *Amer. J. Physiol.*, 1955, **181,** 532–538. [Dept. Anat., State Univ. Iowa, Iowa City.]

Experiments with pregnant rabbits and rats are recorded in which the mother was given infusions of glucose or fructose over a 2-hr. period and the relations between the concentrations of these sugars in the maternal and foetal blood were studied. Foetal glucose concentrations followed those of the mother closely, but foetal fructose concentrations did not follow those of the mother and always remained much lower. Studies on the glucose and fructose concentrations in the foetal and placental tissues showed that fructose, but not glucose, accumulated in the placenta. Phloridzin did not alter these results, which were similar at all stages of pregnancy. The placenta therefore offers a barrier to fructose, but not to glucose.

A. T. Phillipson.

TALBERT, G. B. and HAMILTON, J. B. **Effect of reduced rate of growth on maturation of the male reproductive system of the albino rat.** *Anat. Rec.*, 1954, **121,** 763–773. [Dept. Anat., State Univ. New York Coll. Med., Brooklyn.]

All the litters of rats used were reduced to 7 animals within 48 hr. after birth. Rats were weaned at 20 days and only those which weighed 43 to 49 g. at 25 days were included in the experiment. The male rats from each litter were divided between the 2 groups. In the first group [numbers not stated] the faster-growing rats were slightly restricted in food intake so that all conformed to a standard curve established in a preliminary experiment, from weaning to 57 days of age. In the second group the daily increment of growth was reduced to one-third of the standard by food restriction. Rats were killed every 2 to 5 days and their reproductive organs were stripped of grossly visible fat, weighed and studied histologically.

In the severely restricted rats the absolute rate of growth of testes, seminal vesicles and ventral prostate was reduced, but relative to bodyweight these organs were larger than those of the control rats. Spermatozoa appeared in the lumen of the seminiferous tubules of both groups at 32 to 35 days of age, despite the differences in bodyweight and testis weight. The rapid maturational growth

seen in seminal vesicles and ventral prostate of control rats after 40 days of age was delayed in the restricted group until after 55 days and that of the prostate was particularly delayed, probably by failure of androgenic stimulation.—D. Duncan.

2176

MILLER, H. and WEETCH, R. S. **The excretion of radioactive iodine in human milk.** *Lancet*, 1955, **269**, 1013. [Sheffield Nat. Centre Radiotherapy.]

A patient thought to have thyrotoxicosis was given 29·5 μC. of ^{131}I by mouth. A few minutes later it was found that she was nursing a 4-month-old baby; nursing was discontinued at once. The milk was extracted and the radio-activity was estimated. Had the milk been given the child would have received 1·3 μC. of ^{131}I in 48 hr., an amount which might have had an adverse effect on the thyroid. Radio-active I should not be given to nursing mothers, or, if the isotope must be given, breast feeding should be discontinued.

BARKOVSKAYA, O. V. Opredelenie skorosti obrazovaniya zheltka v yaitze kur. [**Determination of the rate of formation of yolk in the hen's egg.**] *Fiziol. Zh. SSSR Sechenova*, 1954, **40**, 722–726. [Rostov. Gosud. Univ. V.M. Molotova.]

The rate of formation of yolk in the hen's egg was estimated from the transfer into the yolk of lipid-soluble dyes given in the feed, and the lamination of such dyes in cross-sections of eggs laid at intervals. Yolk is deposited immediately under the vitelline membrane, and rate of deposition increases with surface area and apparently depends on the growth of the follicular membrane. The mass of yolk substance is formed from material carried in the blood supplying the follicular membrane.—D. W. Taylor.

RAGOZINA, M. N. Sposoby pitaniya i dykhaniya sel'skokhozyaistvennykh ptitz v razlichnye periody razvitiya vo vremya inkubatzii. [**Means of nutrition and breathing of domestic fowls in different periods of development during incubation.**] *Izv. Akad. Nauk. SSSR Ser. Biol.*, 1955, No. 4, 95–111. [Inst. Animal Morphol., Acad. Sci. SSSR.]

Embryonic organs which perform a principal function at one stage of development of the embryo are rudimentary at the previous stage. These rudiments are only supplementary at first in the function of which they will later become the principal agents. When this function is fulfilled and the embryo has developed further they do not entirely lose their use during the next stage of development. Thus a chicken which has emerged from the egg membranes continues to use the yolk in the yolk sac as food, even although 24 hr. after hatching its main source of nutrients is the food which it picks up for itself. The allantois, mainly respiratory during the early embryonic stages, still preserves a functional significance at the start of hatching, when the respiratory function has been taken over by lungs.—H. Scherbatoff.

SENESCENCE

2181

HORVATH, S. M., RADCLIFFE, C. E., HUTT, B. K. and SPURR, G. B. **Metabolic responses of old people to a cold environment.** *J. Appl. Physiol.*, 1955, **8**, 145–148. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

Temperature and energy exchange studies were made with 8 elderly subjects, average age 64 years, and 7 young subjects, average age 25·5 years. Control measurements were taken in a room with ambient temperature 28° C., after which the subject was moved to another with temperature 10° C. For the elderly, mean values for respiratory minute volume, oxygen consumption, respiratory quotient and heat production were, under control conditions, 8·92 litres, 227 ml. per min., 0·79, 34·0 Cal. per sq. m. per hr.; in the cold 9·84, 242, 0·83 and 36·9. For the young subjects mean values were 7·27, 226, 0·86 and 35·4 in control and 11·93, 359, 0·94 and 57·5 in the cold. The differences between warm and cool conditions were statistically significant for the young but not for the old people.—D. Harvey.

TETZNER, E. Nachweis spezifischer Proteinasen im Harn beim nutritiv-allergischen Schock mittels der Abderhaldenschen Abbauferment-reaktion. [**Demonstration of specific proteinases in urine in shock from food allergy by means of the Abderhalden reaction for hydrolysing enzymes.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1735–1736. [Kreiskrankenhaus, Soltau, Hanover.]

The author, who was allergic to peas and lentils, induced a typical allergic shock reaction by eating a small quantity of pea protein. The reactions for proteinases in the urine were studied before and for 8 days after the induction of allergy. Reactions with bean protein, human carcinoma protein and human albumin were consistently negative, but positive reactions with pea protein were present after from 2 to 6 days and especially on the fourth day.—D. Duncan.

2184

HEDGECOCK, L. W. **Effect of dietary fatty acids and protein intake on experimental tuberculosis.** *J. Bacteriol.*, 1955, **70,** 415–419. [Res. Lab., Veterans Admin. Hosp., Kansas City, Mo.]

Groups of 20 female mice were fed to appetite for 37 days on a basal diet, to which was added 5 per cent. of fatty acid methyl esters and in which the protein content was adjusted, by varying the amount of starch, to 10, 20, 30 or 40 per cent. The fatty acid methyl esters were compounded to simulate coconut oil and consisted of laurate 50, myristate 25, palmitate 20, stearate 2, oleate 2 and linoleate 1 per cent. On the tenth day the mice were injected intravenously with dilutions of a culture of *Mycobacterium tuberculosis*, and the death rate in each group was studied for the ensuing 27 days. Control animals received the Rockland mouse diet.

The mixture of fatty acid esters in the diet enhanced resistance to infection, especially when the ration contained 20 per cent. protein.

In similar experiments in which 5 per cent. lard or 0·2 per cent. methyl linoleate was substituted for the methyl esters there was no increase in resistance to *M. tuberculosis*. Possible reasons for the effect of the methyl esters are discussed.

G. A. Garton.

2185

FULTON, J. D. and SPOONER, D. F. **The biochemistry and nutrition of *Plasmodium berghei*.** *Indian J. Malariol.*, 1955, **9,** 161–176. [Nat. Inst. Med. Res., Mill Hill, London.]

The discovery of *Plasmodium berghei* by Vincke and Lips in 1948 provided a convenient organism for biochemical studies of malaria. It infects a wide variety of rodents, and enters preferentially into the reticulocytes. Knowledge about the parasite is here collected and reviewed, the subjects included being chemical composition, respiration, carbohydrate metabolism and nutritional needs.

E. M. Hume.

2186

SAUTET, J. and CAPORALI, J. Influence chez la souris blanche de divers régimes sur l'évolution de *Plasmodium berghei*. [**Influence of different diets on the development of *Plasmodium berghei* in the white mouse.**] *Méd. trop.*, 1955, **15,** 222–228. [Lab. Hyg., Marseilles.]

Three groups of 5 weanling mice were fed for 12 weeks on bread and water, or bread and raw milk, or bread and pasteurised milk. The raw milk had more fat than the pasteurised milk. All the mice were inoculated with *Plasmodium berghei*. There was little difference between the groups in survival time or proportion of red cells parasitised; the group having raw milk had slightly more resistance. In a second experiment the 2 kinds of milk had the same fat content, but the result was no more conclusive than in the first experiment. There were wide individual variations.—E. M. Hume.

2187

SEN, H. G., DUTTA, B. N. and RAY, H. N. **Milk diet in *Trypanosoma evansi* infection in rats.** *Indian J. Vet. Sci.*, 1955, **25,** 117–120. [Sch. Trop. Med., Calcutta.]

Young rats were given a stock diet with or without 100 ml. pasteurised milk daily (see Sen, *et al.*, *Bull. Sch. Trop. Med., Calcutta*, 1954, **1,** 17). When they were infected with *Trypanosoma evansi* there was no significant difference in the course of the infection or in mortality.—D. Duncan.

2188

SEN, H. G., DUTTA, B. N. and RAY, H. N. **Effect of starvation on the course of experimentally induced *Trypanosoma evansi* infection in rats.** *Indian J. Vet. Sci.*, 1955, **25,** 143–148. [Sch. Trop. Med., Calcutta.]

Rats were fed on a stock diet of bread, milk, gram, vegetables, yeast and cod liver oil. Fasting, in one experiment for 4 days before and 6 days after inoculation [the time is not clear in the other 2 experiments], did not affect the course of infection with *Trypanosoma evansi*.—D. Duncan.

2189

Ross, R. T., Holtman, D. F. and Gilfillan, R. F. **The effect of *Salmonella pullorum* infection on amino acids of the chick.** *J. Bacteriol.*, 1955, **70,** 272–275. [Dept. Bacteriol., Univ. Tennessee, Knoxville.]

The blood and liver of chickens infected with a virulent strain of *Salmonella pullorum* showed a marked decrease, compared with normal chickens or chickens inoculated with a non-virulent strain, in the concentrations of arginine, methionine, glycine and tryptophan. Since studies *in vitro* have shown that the organism has no specific need of these amino-acids, it is suggested that the host uses them in defence against the parasite.

J. S. Thomson.

2190

Ross, R. T., Holtman, D. F. and Gilfillan, R. F. **The effect of the introduction of amino acids into chicks infected with *Salmonella pullorum*.** *J. Bacteriol.*, 1955, **70,** 276–278. [Dept. Bacteriol., Univ. Tennessee, Knoxville.]

In an experiment similar to the above (see preceding Abst.), glycine, arginine, methionine and tryptophan or a mixture of these were given orally or intraperitoneally to chickens infected with the virulent strain. Only arginine lengthened the time of survival to any extent; methionine delayed death slightly. Death occurred usually within 84 hr., but with arginine after 144 hr. The addition of arginine 48 hr. before infection did not increase the time of survival.—J. S. Thomson.

2191

Cohen, S. S. and Barner, H. D. **The death of bacteria as a function of unbalanced growth.** *Pediatrics*, 1955, **16,** 704–708. [Child. Hosp., Philadelphia, Pa.]

Turba, F. and Esser, H. Zeitlicher Verlauf des Einbaues von C^{14} in Aminosäuren, Peptide und Proteine von Torulazellen. [**Time relations in the incorporation of ^{14}C into amino-acids, peptides and proteins of torula cells.**] *Biochem. Ztschr.*, 1955, **327,** 93–108.

Yeast cells, *Torula utilis*, were grown with acetate-1-^{14}C as their only source of C. They incorporated ^{14}C most quickly into amino-acids; peptides were labelled before proteins. Besides glutathione, some 40 acid peptides were separated and their component amino-acids were studied. Glutamic acid was the chief component, then glycine, aspartic acid, alanine and serine.

The role of peptides in protein formation is discussed.—D. Duncan.

2193

Müller, R. and Krampitz, G. Untersuchungen in vitro zur Frage der Stickstoff- und Schwefelumsetzungen im Pansen. [**Studies *in vitro* of nitrogen and sulphur metabolism in the rumen.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, **65,** 187–198. [Inst. Anat. Haustiere, Univ. Bonn.]

For an earlier paper see Müller and von Erichsen, *Ztschr. Tierzücht. Züchtungsbiol.*, 1952, **60,** 285.

Experiments with an artificial rumen are described in detail. When 600 ml. fresh rumen contents from slaughtered cattle were incubated with 10 or 20 g. dextrose and 20 μC. $^{35}SO_4^{--}$ for 4 hr., the rumen bacteria, but not the protozoa, took up considerable amounts of sulphate. Uptake of S was inhibited by formaldehyde or penicillin. The results are taken to confirm the finding of Block *et al.* (Abst. 5104, Vol. 21) that sulphate is reduced and built up into sulphur amino-acids.

In the remaining experiments 150 ml. rumen contents from one or other of 4 sheep with a fistula were used; when samples were withdrawn the micro-organisms were precipitated with trichloroacetic acid and total N and ammonia N were estimated in the protein-free fluid. In most, but not all, of the experiments there was evidence of protein synthesis, and in these S was taken up. Where there was protein breakdown, S was not taken up. Addition of 8 g. molasses favoured protein synthesis, in agreement with the results of others (Absts. 3909, Vol. 21; 1354, Vol. 13). The presence of readily fermentable carbohydrate is thought to provide lower fatty acids which absorb ammonia and form amino-acids. Slightly acid conditions favoured protein synthesis, although the natural *p*H of the rumen contents ranged from 7·6 to 8·0.

The results could not be related to the diet of the animals; variations are ascribed to individuality of the rumen micro-organisms.—W. M. Deans.

MISCELLANEOUS FEEDING EXPERIMENTS

2194

RUOSTEENOJA, R. **Effect of food intake on the cardiovascular response to cigarette smoking.** *Ann. med. exp. Fenn.*, 1955, **33,** 320–325. [Inst. Occupat. Health, Helsinki.]

Tests made on 10 young men, 5 smokers and 5 non-smokers, showed that the rise of pulse rate and fall of skin temperature on smoking a cigarette were greater after fasting for 15 hr. than when food had been taken before smoking. Changes in diastolic and systolic blood pressure in response to smoking were much the same in the fasting state and after food.—A. M. Copping.

2195

JAMES, W. T. and GILBERT, T. F. **The effect of social facilitation on food intake of puppies fed separately and together for the first 90 days of life.** *Brit. J. Animal Behaviour*, 1955, **3,** 131–133. [Univ. Georgia.]

For 90 days from weaning 3 beagle × terrier puppies were reared together but fed separately, and 3 others, similar but from a different litter, were fed together once a day; then for the next 40 days the puppies of each group were fed separately on one day and together on the next and intake of food, Purina chow of uniform consistency, was found by weighing the puppies before and after the feed.

As was expected from earlier work by the author and others (*e.g.*, James, *J. Comp. Physiol. Psychol.*, 1953, **46,** 427), more food was eaten on the days when the puppies were fed together, but the group that were originally fed separately did not show the effect for about 14 days; in the other group the effect was immediate.—W. M. Deans.

2196

TOWBIN, E. J. **Thirst and hunger behavior in normal dogs and the effects of vagotomy and sympathectomy.** *Amer. J. Physiol.*, 1955, **182,** 377–382. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

MARDONES R., J., SEGOVIA-RIQUELME, N., HEDERRA D., A. and ALCAÍNO G., F. **Effects of some self-selection conditions on the voluntary alcohol intake of rats.** *Quart. J. Studies Alcohol*, 1955, **16,** 425–437. [Inst. Invest. Alcoholismo, Univ. Chile, Santiago.]

The voluntary alcohol intake of rats was measured with purified diets given as a normal mixture, or with sucrose separated from the other components, or as mixtures high or low in sucrose. Self-selection of sucrose and other components did not significantly change the intake of alcohol. Variation in the proportion of sucrose in a ready-mixed diet did not affect alcohol intake. A third choice, of sucrose or dextrose in solution, caused a significant decrease in alcohol intake. The effect was similar with sugar solutions differing widely in concentration. When a solution of B vitamins was offered instead of a sugar solution there was no change in alcohol intake, although the rats showed a strong preference for the vitamin mixture.—A. M. Copping.

2198

VARTIAINEN, I. and PAASONEN, M. **Selection of phosphorus in alloxan diabetes.** *Endocrinology*, 1955, **57,** 513–515. [2. Med. Clin., Univ. Helsinki.]

Normal and alloxan-diabetic rats were offered a choice of several of the foods listed below with their percentage content of P: casein 0·58, meat powder 0·43, egg yolk powder 0·54, fat-free egg yolk powder 0·85, egg yolk oil 0·33, fish powder 0·54, milk powder 0·58, semolina 0·20, dibasic sodium phosphate or sodium pyrophosphate in 2 per cent. solution. They received also 50 per cent. sucrose solution and olive oil, with additional salts, trace elements and vitamins as described elsewhere (Abst. 5465, Vol. 25).

In 28 days the groups of control rats ate on the average from 1·8 to 3·8 g. P per kg. bodyweight and the diabetic groups from 7·0 to 13·2 g. P per kg. bodyweight. The latter consistently ate more phosphoric acid salts than the controls, as well as more P-containing protein foods.—D. Duncan.

2199

HARRIMAN, A. E. **The effect of a preoperative preference for sugar over salt upon compensatory salt selection by adrenalectomized rats.** *J. Nutrition*, 1955, **57,** 271–276. [Dept. Psychol., Franklin and Marshall Coll., Lancaster, Pa.]

Four groups of 24 rats aged initially 65 to 75 days and caged individually received a diet containing 0·007 per cent. Na and 0·1 per cent. K. Two groups were allowed to choose either 8 per cent. sugar solution or 1·2 per cent. salt solution instead of drinking water for 18 or 20 days, the other 2 groups had water. Rats of one group on each treatment then had their adrenals removed and those of the other group had sham operations, after which all 4 groups had the choice of sugar or salt solution for another 15 days.

Before operation the rats allowed salt or sugar solution strongly preferred sugar. After operation this preference continued in both groups. Of the rats newly introduced to choice after operation, those with adrenals removed selected salt and those given the sham operation selected sugar. The result was that the rats which had developed a taste for sugar failed to increase their salt intake when their adrenals were removed; 4 of them died and the others lost much weight. The difference was significant.—D. Duncan.

2200

McCance, R. A. and Widdowson, E. M. **Some undescribed effects of over and undernutrition.** *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 79–87. [Med. Res. Counc. Dept. Exp. Med., Univ. Cambridge.] German and French summaries.

This is a preliminary report.

Pigs were held at a weight of 10 to 15 kg. for months when they received only 250 to 350 g. of a normal diet daily. They had coarse hair and continually rubbed themselves, and 2 developed multiple staphylococcal abscesses subcutaneously. Some had gross abdominal distention from gas in the intestinal tract. The long bones were short, but wider than in normal pigs of the same weight. The brain cavity and pituitary fossa were about normal for age, but the rest of the skull and the jaw were retarded in growth. The composition of soft tissues is briefly discussed.

Three pigs given unlimited amounts of the same diet may have been overfed. They were very fat and oestrus was delayed.—F. C. Aitken.

Homb, T., Husby, M. and Breirem, K. Versuche mit Weissbrot und Weizenvollkornbrot bei Schweinen. [**Experiments on pigs with white bread and whole wheat bread.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 203–211. [Norges Landbrukshøgsk., Vollebekk.]

The pig part of the experiments of Nicolaysen and Njaa (Abst. 2318, Vol. 21) on the effect of phytic acid on absorption of Ca is reported again because of its interest in other respects. Two pairs of 10-week-old pigs were fed on white bread from flour of 65 or 70 per cent. extraction or on whole wheat bread of the same moisture content, with skimmed milk, salt, cod liver oil and Ca. After a pre-period of 8 weeks, there were 7 balance periods of 2 weeks each, during the 5th and 6th of which the rations were interchanged.

When the pigs had white bread their faeces were scanty, dry and hard compared with those when they had whole wheat bread. Constipation did not seem to affect their general condition or rate of growth, which were considered good on both rations; it was prevented by adding 150 g. ground sulphite cellulose daily to the white bread ration. Before this addition, rate of daily gain over a 3-month period from 23 kg. bodyweight was 564 g. for white bread and 537 g. for whole wheat bread. Digestibility coefficients for the different nutrients, except crude fat, were significantly higher for white than whole wheat bread. Efficiency of feed utilisation did not differ. The pigs throve even although the white bread ration alone had as little as 1·5 per cent. crude fibre in the dry matter and the whole wheat ration, with 3·1 per cent., had less than is usual in pig feeding.—W. M. Deans.

Heinicke, H. R. and Elvehjem, C. A. **Effect of high levels of fat, lactose, and type of bulk in guinea pig diets.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 70–72. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Three groups of guineapigs were given a normal diet which consisted, per cent., of sucrose 43, casein 30, bulk 15, salts 4, maize oil 4, potassium acetate 2·5, choline chloride 0·75, magnesium oxide 0·5 and a vitamin B group mixture 0·25, supplemented with vitamins A, D, E and K; a high-fat diet containing 24 per cent. maize oil, the addition being made at the expense of sucrose; or a diet in which lactose was the only source of carbohydrate. After adaptation to the diet each of the groups was subdivided into 3 groups of 5 guineapigs. With these 9 groups the effect of the type of bulk on growth was studied, the types used being gum acacia, spangles and Solka-Floc. The 3 normal groups were studied for 4 weeks, after which they were redistributed and given diets with 4, 8 and 12 per cent. maize oil with Solka-Floc as the bulk for 3 weeks; the 3 groups receiving high-fat diets were studied for 6 weeks, after which the livers were analysed for fat; the groups receiving lactose as the carbohydrate were studied for 2 weeks, after which 12 remaining animals were redivided into 2 groups of which one continued to receive lactose as the only carbohydrate while the other had half of the lactose replaced by sucrose, both groups receiving Solka-Floc as the bulk and being studied for 4 weeks.

The average growth rate of the groups receiving Solka-Floc was slightly better in all experiments. The animals given 12 per cent. maize oil grew at the rate of 7·7 g. and those given 24 per cent. maize oil at 4·9 g. daily when Solka-Floc was the bulk. Animals on the diets with lactose as the sole source of carbohydrate grew at the rate of about 2 g. daily. The substitution of sucrose for half the lactose more than doubled the rate of growth.—G. F. Garton.

SUR, B. K. **Supplementary value of leaves to the poor rice diet.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1955, **4**, 159.

In continuation of earlier work (Abst. 774, Vol. 20) the supplementary value of leaf flours of lucerne, Dub grass (*Cynodon dactylon*), drumstick (*Moringa oleifera*), pumpkin (*Cucurbita pepo*) and amaranth (*Amaranthus gangeticus*) at a 10 per cent. level was tested on rats on a poor South Indian rice diet. Lucerne, Dub grass and drumstick had high supplementary values, but amaranth had a low value, possibly because of its high oxalic acid content.—J. S. Thomson.

2204

CABELL, C. A. and ELLIS, N. R. **Feeding value of stored corn.** *J. Animal Sci.*, 1955, **14**, 1167–1173. [Animal and Poultry Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

In experiments with rats the feeding values of samples of yellow maize stored in good conditions for from 1 to 6 years at 3 centres were compared. At one centre there was a lower protein value after 5 years; otherwise protein and energy values were not affected by storage.—T. D. Bell.

2205

HOGAN, A. G., GILLESPIE, G. T., KOÇTÜRK, O., O'DELL, B. L. and FLYNN, L. M. **The percentage of protein in corn and its nutritional properties.** *J. Nutrition*, 1955, **57**, 225–239. [Dept. Agric. Chem., Coll. Agric., Univ. Missouri, Columbia.]

Groups of 6 male rats of Wistar strain were used in studies on high-protein maize and rats of Sprague Dawley strain in studies on low-protein maize. The high-protein maize contained 16·1 per cent. protein, was white and was grown in Illinois; the low-protein maize contained 7·3 per cent. protein, was yellow and was grown in central Missouri. When animals were given diets containing 94 per cent. high-protein maize plus 0·5 per cent. DL-threonine, or 94·5 per cent. low-protein maize, with salts 4, $CaCO_3$ 1·0 and soya bean oil 0·5 per cent., growth was slow; these diets contained 15 and 7 per cent. protein, respectively.

Rats which received the high-protein diet showed a slight increase in the rate of gain in bodyweight when given supplements of tryptophan and larger responses when given nicotinic acid or lysine; no response was statistically significant. When nicotinic acid and lysine were added simultaneously to the high-protein diet the response was increased further, and even more by supplements of tryptophan and lysine given simultaneously; these responses were statistically significant. Rats did not grow more rapidly on a combination of nicotinic acid and tryptophan than on nicotinic acid alone.

Rats given the low-protein diet grew more slowly than those given the high-protein diet. They gave no response to single additions of either tryptophan or nicotinic acid or to the combination of tryptophan and nicotinic acid. The response to lysine alone was not statistically significant and the response to lysine and nicotinic acid was no greater than to lysine alone. The response when lysine and tryptophan were added simultaneously was highly significant.

In the samples of maize studied, lysine was the first limiting factor and tryptophan the second; threonine was not a limiting factor in the high-protein maize. The nutritive value of the protein in the low-protein maize was superior to that of the protein in the high-protein maize; per unit of weight, the high-protein maize was superior to the low-protein maize. As a source of protein for the rat, maize protein supplemented with lysine and tryptophan was inferior to casein.

G. F. Garton.

SUR, G., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Studies on the nutritive value of Jowar (Kaffir corn—*Sorghum vulgare*).** *Bull. Central Food Technol. Res. Inst., Mysore*, 1955, **4**, 133–134.

Six purebred strains of sorghum showed the following range in composition: moisture 10·4 to 13·0, protein 9·7 to 10·3, fat 2·8 to 3·2, ash 1·6 to 1·9 per cent.; Ca 51·4 to 127·3, P 149·6 to 204·0, Fe 1·1 to 2·6 and vitamin B_1 0·28 to 0·33 mg. per 100 g. In growth experiments with rats sorghum was shown to be inferior to wheat as a source of protein, minerals (except Ca) and vitamin B_1. Poor vegetarian diets containing either sorghum or wheat, each supplemented with pulses, showed similar growth-promoting effects.—J. S. Thomson.

FENG, P. C. and KEAN, E. A. **Influence of diet on the acute toxicity of hypoglycin-A in rats.** *Brit. J. Nutrition*, 1955, **9**, 368–373. [Div. Pharmacol., Dept. Physiol., Univ. Coll. W. Indies, Jamaica.]

Groups of rats were fed from weaning on a Jamaican diet mainly of vegetables as commonly eaten by the poorer classes of Jamaicans, a modified Jamaican diet similar to the first but with some carbohydrate replaced by casein, and a stock diet. After from 6 to 8 weeks on the diets the animals were examined by an acute toxicity test. Hypoglycin-A, the toxic polypeptide from the fruit of *Blighia sapida*, was dissolved in water and injected subcutaneously in doses of from 10 to 150 mg. per g. bodyweight. Deaths within 72 hr. after injection were recorded.

The rats fed on the unmodified Jamaican diet were more susceptible than the others, and all the rats on the diet given 40 μg. hypoglycin-A per g. bodyweight succumbed, but 70 μg. caused no death among the rats given the other 2 diets. The rats having the Jamaican diet did not grow and usually lost their hair. Modification of the Jamaican diet by replacing some of the carbohydrate with 10 per cent. protein improved growth very little. The resistance of the animals to hypoglycin-A was not related to their capacity for growth, since the lethal dose for the rats given stock diet was similar to that for those given the modified Jamaican diet. The mean glycogen content of the liver of 5 rats given the Jamaican diet was 7·17 g. per 100 g. wet tissue ; the corresponding figure for rats given stock diet was between 3 and 4. There was no significant pathological change when the livers were examined histologically. Blood glucose, estimated in 29 moribund rats, showed severe hypoglycaemia, with values usually below 20 mg. per 100 ml. It is suggested that the carbohydrate : protein ratio of the diet influenced the toxicity of hypoglycin-A.

GERSHOLOWITZ, P., WEIDERSHEIM, M. and TUCKER, R. D. **Preparatory experiment on protection of skin against irradiation damage.** *S. African Med. J.*, 1955, **29,** 846–847. [Cape Town.]

Of 4 groups, each of 3 rats, 2 were given diets consisting entirely of homogenised uncooked bovine spleen, or half spleen and half a normal stock diet ; a fifth group was given the normal diet. Two weeks later each animal was exposed, in 3 areas of its skin, to X-rays in doses of 2000, 4000 and 6000 r. Of those receiving spleen one group continued on the all-spleen and another on the half-spleen diet, the 2 others reverted to the normal diet, and the fifth remained on it. At the end of 3 weeks damage was found to be greatest in the control rats which had had no spleen in their diet, and less in those given spleen than in those on the normal diet after exposure.—D. Harvey.

MAYER, J., FRENCH, R. G., ZIGHERA, C. F. and BARRNETT, R. J. **Hypothalamic obesity in the mouse. Production, description and metabolic characteristics.** *Amer. J. Physiol.*, 1955, **182,** 75–82. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The apparatus and method by which hypothalamic lesions were produced in mice are described ; they were adapted from those used for rats.

Normal female Swiss mice were found to weigh between 35 and 40 g., so operated mice were considered obese if their weight exceeded 45 g. The coordinates for the stereotaxic instrument are tabulated : with the most successful set of coordinates 11 out of 24 mice were made obese, 9 died and 4 operations failed. Animals which became obese usually gained 15 to 20 g. within 2 weeks after operation ; one reached 82 g. in 38 days. Liver and ovary weight were significantly below normal in obese mice.

When examined after death, obese mice always showed bilateral destruction of parts of the ventromedian nuclei and usually of the arcuate and periventricular nuclei. The median eminence and the brain substance ventral to the third ventricle were usually destroyed. The lateral hypothalamic area, mamillary bodies, para-ventricular and supraoptic nuclei were always intact.

Obesity was successfully induced in 2 out of 13 non-obese littermates of mice with hereditary obesity and diabetes. Their behaviour after operation did not differ from that of the Swiss mice. Except that about half the animals showed transitory excitement for 2 or 3 hr. after operation, usually running wildly about, the aggressive behaviour characteristic of hypothalamic obesity in rats was not observed. The obese mice were extremely inactive. Their B.M.R. when based on surface area was not significantly different from the normal. After fasting to reduce their weight, obese mice regained weight most rapidly on a high-fat and least rapidly on a high-protein diet. Blood sugar, sensitivity to insulin and response to growth hormone were normal.

Hypothalamic obesity is compared with spontaneous obesity and that produced by gold thioglucose.—D. Duncan.

HOLLIFIELD, G., PARSON, W. and CRISPELL, K. R. **Studies of food drive and satiety in mice with gold thioglucose-induced obesity and the hereditary obesity-diabetes syndrome.** *Metabolism*, 1955, **4,** 537–541. [Dept. Int. Med., Sch. Med., Univ. Virginia, Charlottesville.]

Studies were made on female mice of the DBA strain or with hereditary diabetes and obesity and their littermate controls ; obesity was induced in the DBA mice by intraperitoneal injection of 20 mg. gold thioglucose when the mice were 3 months old. Six gold-obese mice and 6 non-obese controls about 4 to 5 months old, 12 gold-obese mice and 12 non-obese controls about 18 to 20 months old and 6 mice with hereditary obesity and 6 non-obese littermate controls about 3 months old were placed in revolving activity cages ; when activity, weights and food intakes became constant they were starved for 24 or 48 hr. and then allowed food to appetite. The ration throughout the study was ground Purina chow pellets. Spontaneous

running activity, weight and food intake were recorded daily.

The gold-obese mice, unlike normal mice, did not increase their running activity during starvation or decrease their activity when allowed food to appetite. The mice with hereditary obesity responded to starvation as normal mice, but when given food to appetite their response was not as striking as that of the normal mice.—G. F. Garton.

NAFTALIN, J. M. **The effect of environment and mode of feeding and of rearing on the production of acute dietary liver necrosis in the rat.** *Ann. New York Acad. Sci.*, 1954, **57**, 862–868. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The environments were similar to those described earlier (Absts. 1038, Vol. 22; 1942, Vol. 23). The young rats received from 17 or 19 days of age a diet containing, per cent., casein (Glaxo "vitamin-free") 16 or 19, brewer's yeast 3, sucrose 68 or 65, lard 7, salt mixture 4, cod liver oil 2, with B vitamins but no added vitamin E. From 6 weeks of age the casein was reduced to 8 per cent. The rats were weaned at 24 days of age. When the low-protein diet was introduced one group in each environment was allowed to eat to appetite, other groups were restricted in intake.

The highest incidence of acute liver necrosis was in rats fed to appetite and kept at 70° to 78° F., especially when they had been weaned on the 17th instead of the 25th day of age. At all environmental temperatures restriction of food intake reduced or prevented necrosis, but when restriction was too great the rats died of inanition and not of necrosis, and the lower the environmental temperature the greater the effects of restriction.

D. Duncan.

2212

NAFTALIN, J. M. **Effect of different makes of casein on the production of acute dietary liver necrosis in the rat.** *Ann. New York Acad. Sci.*, 1954, **57**, 869–872. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The diets were as described in the preceding Abst., but the caseins were Glaxo lactic casein "C" unextracted and Genatosan "low-vitamin" casein. Young rats weaned on the 17th day were given these diets to appetite, and from the 38th day the casein was reduced to 8 per cent. and sucrose was increased. In one experiment a group of 10 rats received the Genatosan casein diet, with a supplement of 0·5 mg. vitamin B_{12} by mouth 3 times a week from 38 days of age. The environmental temperature was 74° to 78° F.

In 2 experiments with the Glaxo casein the mean survival of rats after the 38th day of age was 7 and 9 days and the mortality was 9 out of 10 and 33 out of 36, all the dead rats showing acute liver necrosis. Four died before the 38th day. With the Genatosan casein 4 out of 10 and 16 out of 36 rats died with liver necrosis. With Genatosan casein and vitamin B_{12}, one rat out of 10 died.

Differences in the preparation of casein are discussed. The Glaxo lactic casein "C" unextracted is a crude product of New Zealand origin. The Genatosan "low-vitamin" casein is usually made from British liquid milk, sometimes with dried skimmed milk from New Zealand added.

D. Duncan.

HALDI, J., WYNN, W., LAW, M. L. and BENTLEY, K. D. (with RAMSAY, D.) **Dental caries in the albino rat in relation to the chemical composition of the teeth and of the diet. 1. Effect of prenatal and postnatal feeding of high protein, high fat and high carbohydrate diets.** *J. Nutrition*, 1955, **57**, 215–223. [Dept. Physiol., Div. Basic Sci. Health Serv., Emory Univ., Emory University, Ga.]

Two generations of rats were bred. The first was from parents on a commercial stock diet and, from weaning, 10 animals in each of 3 groups were given synthetic diets rich in sucrose, casein or fat. They were killed after 150 days. The second was from a similar F_1 generation and the young were reared and later fed for the same length of time on one of these same 3 diets, offspring getting the same one as their mother. Teeth were analysed for N, Ca, P, Mg, F and CO_2.

From data for both sets of rats no difference for any constituent was found among the groups within the generations. The commercial and synthetic diets differed considerably in mineral content, but not so the teeth of the F_1 and F_2 generations. The evidence seemed to support the view that, with supplies of these nutrients above certain minimum levels, genetic rather than nutritional circumstances would determine the amounts which would be deposited in teeth.

Incident to the work was the conclusion that the increase in amount of caries with the high-sucrose diet (see Abst. 2665, Vol. 22) could not be ascribed to a difference in the mineral composition of the teeth.—D. Harvey.

2214

BOMBARA, G. L'edema da ovoalbume nel ratto albino nell'inanizione acuta. [**Egg-albumin oedema in the white rat fasting completely.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 120–124. [Ist. Patol., Univ. Messina.]

Egg-albumin oedema of the rat, first described by Seyle (*Endocrinology*, 1937, **21**, 169), was induced by injecting 1 ml. fresh egg white intraperitoneally

into groups of 15 rats normally fed, or after they had fasted until from 24 to 35 per cent. of weight had been lost, or after from 38 to 50 per cent. loss. When fully fed the rats showed the normal degree of oedema, but after fasting the appearance of oedema was completely suppressed in 6 and 5 rats, respectively, and in the remainder it was slight and transitory.—E. M. Hume.

GENERAL METABOLISM AND FEEDING HABITS OF ANIMALS OTHER THAN MAMMALS AND BIRDS

FROMM, P. O. and JOHNSON, R. E. **The respiratory metabolism of frogs as related to season.** *J. Cell. Comp. Physiol.*, 1955, **45,** 343–359. [Coll. Liberal Arts Sci., Dept. Physiol., Univ. Illinois, Urbana.]

Total oxygen consumption of frogs (*Rana pipiens*) was studied in a closed circuit respirometer; the frogs were immobilised with curare, but recovered subsequently. Frogs were unfed, or forcibly fed with tuna fish homogenate, and kept at 22° to 28° C. or 4° C.

Despite the constant room conditions there was a seasonal peak of oxygen consumption and CO_2 production in spring. The respiratory quotient was very high, mean 1·20, in autumn and declined slowly to 0·82 in spring and summer. Refrigeration of both fed and unfed frogs reduced oxygen consumption but not CO_2 production, and substantially increased the R.Q. Feeding had little or no effect at any season on oxygen consumption, CO_2 production or R.Q.—D. Duncan.

BIRSHTEIN, YA. A. and VINOGRADOV, M. E. Zametki o pitanii glubokovodnykh ryb Kurilo-Kamchatskoi vpadiny. [**The food of deep-sea fish of the Kurile-Kamchatka deeps.**] *Zool. Zh.*, 1955, **34,** 842–849. [Lomonosov Moscow State Univ., USSR.]

The difficulty with this investigation was that in raising deep-sea fish to the surface from great depths their intestines emptied under pressure from the enlarged swim-bladder, so with occasional exceptions it was possible to judge the nature of their food only from remnants in the mouth.

The principal food of *Coryphanaenoides cinereus* was plankton: crustaceans, oarfish and the like. *C. angustifrons* (one full intestine only) feeds on crustaceans of the ocean floor and just above it. Much more material was available for *C. acrolepsis*, which by its food should be judged a pelagic fish and not a fish of the ocean floor. These fish have a wide range of food, necton and macroplankton, not relatively small animals such as are eaten by the first 2 fish mentioned. They probably use their enormous eyes in hunting for food and are attracted primarily by luminous organisms. Their food habits change with age, starting with oarfish found at depths of 100 to 200 m., then *Calanus cristatus* (at the fifth stage of development) found at 50 to 500 m.; as no deep-water oarfish were found in the intestines of young fish, they presumably do not descend below 500 m. Adult *C. acrolepsis* appear to feed at depths below 2000 to 3000 m.

The principal food of 2 species of *Lampanyctus*, *L. leucopsarus* and *L. nannochir laticauda*, was *Calanus cristatus*. Of the other kinds of fish caught, *Bassozetus zenkevitchi* and 2 kinds of *Melamphaes* fed on plankton, whereas *Careproctus amblystomopsis* was without doubt a benthos feeder, as the large egg of an octopod which is always attached to the bottom was found in its intestine, and also the chaetae of ocean floor polychaets. Two deep-sea eels, *Ilyophis brunneus* and *Histiobranchus infernalis*, from a depth of 3000 m. can also be counted among the benthos fishes; in the stomach of the latter, in addition to ocean floor *Amphioda*, was found the small fruit of *Thelycrania alba*, a land flowering plant, which confirms previous findings that deep-sea animals can use residues of land plants as food.

H. Scherbatoff.

GERKING, S. D. **Influence of rate of feeding on body composition and protein metabolism of bluegill sunfish.** *Physiol. Zoöl.*, 1955, **28,** 267–282. [Dept. Zool., Univ. Indiana.]

Bluegill sunfish of initial weight about 30 g. were kept in individual glass tanks and fed on mealworms at rates of from 1·16 to 3·59 per cent. of bodyweight daily for 30 days. Sample fish were

analysed at the beginning of the study and all fish at the end. Nitrogen retention was calculated by subtracting the N of the initial sample fish from that of a fish analysed at the end. N equilibrium was maintained on a daily intake of 7·2 mg., above which there was increasing retention of N. Maximum efficiency of utilisation of protein appeared to depend on maximum consumption of protein. The total body composition of the fish fed at different rates showed some variation, especially in fat content, which increased as the amount of feed increased.—A. M. Copping.

2219

IVLEV, V. S. Zavisimost intensivnosti obmena u ryb ot vesa ikh tela. [**Dependence of the intensity of metabolism in fish on the bodyweight.**] *Fiziol. Zh. SSSR Sechenova*, 1954, **40**, 717–721. [Latviisk. Otdel VNIRO.]

Oxygen consumption was measured in a large number of species of fish at a constant temperature of 18° to 20° C. Rate of oxygen consumption plotted against bodyweight gave a straight line, from which few values deviated. A mathematical expression is derived for the relationship. The implications of these experiments and the conditions influencing body temperature are discussed in terms of the concept of "active" or "protoplasmatic" and "indifferent" components of the body mass.—D. W. Taylor.

BOLDAREV, V. O. Plodovitost' i pishchevaya spetzializatziya sibirskogo shelkopryada (*Dendrolimus sibiricus* Tshtv.). [**The fertility and nutritive specialisations of the Siberian silkworm (*Dendrolimus sibiricus*, Tshtv.).**] *Zool. Zh.*, 1955, **34**, 810–821. [Irkutsk Reg. Forestry Admin.]

The low fertility of the Siberian silkworm, a pest of some coniferous and other trees, in pine woods led to the conclusion that the caterpillars feed on pines only when no other trees are available and that they are on a starvation diet in pinewoods, where most of them perish at an early stage of development.

In laboratory experiments it was discovered that the caterpillars developed best on larch, with *Abies* next, with an average development on cedar and worst of all on pine and spruce needles. There was no reason to believe that there were 2 races. The largest and heaviest pupae, up to 6 g., developed on larch and became the most fertile in the adult stage (up to 826 eggs), with average size and fertility on cedar (up to 400 eggs), while on pine and spruce needles most of the caterpillars died. Although caterpillars on larch were heaviest and most developed they produced least excreta, 1595 pieces as against 2027 on cedar and 2097 on pines; the softer the needles, as in larch, the less the excreta produced.

The caterpillars did most damage to trees in the later stages of development, in the autumn preceding their second winter and in the next spring before pupating, which is the period when they have to build up reserves for the next stage of development.—H. Scherbatoff.

FRAENKEL, G. **Inhibitory effects of sugars on the growth of the mealworm, *Tenebrio molitor* L.** *J. Cell. Comp. Physiol.*, 1955, **45**, 393–408. [Dept. Entomol., Univ. Illinois, Urbana.]

Larvae of the mealworm, *Tenebrio molitor*, L., were grown on semi-synthetic diets (see Abst. 1764, Vol. 21) with vitamins of the B complex, including carnitine, and 2 per cent. brewer's yeast. The carbohydrates tested were given as 80 per cent. of the diet.

The larvae grew well on glucose, maltose, dextrin, starch or glycogen and moderately well on mannitol, lactose, melibiose, trehalose, cellobiose, raffinose or melezitose. They grew well for a short time on sucrose and then died. They failed to grow on arabinose, xylose, galactose, sorbose, inulin, cellulose, rhamnose, ribose, α-methylglucoside or α-methylmannoside. They died very quickly on fructose, mannose, sorbitol or dulcitol. Results with lactose were variable. Cellulose was inert.

Sucrose, fructose and sorbitol, which were all hygroscopic and became too wet for the larvae, when mixed with equal parts of starch were as good as, or better than, starch alone.

When mixed with starch or glucose, arabinose, xylose, rhamnose or ribose retarded growth at levels of from 2 to 20 per cent. of the diet; so did galactose, mannose or sorbose, and dulcitol and α-methylglucoside were particularly toxic. Toxic effects were greater with glucose than with starch.

Intestines of larvae were homogenised and tested for enzyme activity. A hydrolysing enzyme was found for every sugar which had given good or fair growth, except melibiose. Lactase was found in 2 out of 5 tests.—D. Duncan.

SRINIVASAN, V., MOUDGAL, N. R. and SARMA, P. S. **Influence of thyroxin and thyroglobulin on rice moth larva.** *Science*, 1955, **122**, 644–645. [Dept. Biochem., Univ. Madras.]

Thyroxine and cattle thyroglobulin, both of known potency, were given to larvae of a pure

strain of rice moth, *Corcyra cephalonica*, St., maintained under standard conditions. In each set of experiments 15 petri dishes were filled with 10 g. white flour and concentrations of thyroxine ranging from 0 to 24 μg. per g. diet, or thyroglobulin from 0·058 to 2·900 μg. per g. diet when expressed as thyroxine equivalent. The petri dishes were then seeded with 5 mg. fresh moth eggs. At the end of 15 days, 2 batches of 10 larvae were picked from each dish and weighed. Thyroxine up to 0·75 mg. per g. diet promoted growth of the larvae, but higher doses inhibited growth and death occurred at the highest concentration. Thyroglobulin at all concentrations failed to show any effect on growth. Thyroxine increased oxygen consumption, but thyroglobulin did not. It is suggested that this may have been due to inability of the larvae to split the protein molecule completely.—B. W. Simpson.

2224

SCHUMARD, R. F., HERRICK, C. A. and POPE, A. L. **The effect of diet on the length of third stage larvae produced by adult *Haemonchus contortus* harbored by lambs.** *J. Parasitol.*, 1955, **41**, 542–544. [Univ. Wisconsin.]

Eggs of *Haemonchus contortus* from lambs on different mineral intakes were cultured in the faeces of uninfested lambs on the same rations. The culture media had no effect on the growth of the larvae, as measured by the third stage. Highly significant differences in length were apparently due to the nutrition of the host of the parents of the larvae. Longer larvae developed from eggs from lambs getting cobaltised salt, 6·72 gm. $CoSO_2$ in 100 lb. iodised salt, and salt with traces of I, Co, Cu, Fe, Mn and Na.—G. C. Hunter.

5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE

DIET

REQUIREMENTS

2226

FRANK, R. M. and JOHNSTON, F. A. **Total energy needs of women 22 to 36 years old.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1007–1009. [New York State Coll. Home Econ.]

Eight women in whom basal metabolic rate was within normal limits were weighed at intervals during 4 months. They were allowed to vary their consumption of such foods as cream, butter and sugar so as to adjust energy intake to needs. In this way it was hoped that the women would maintain bodyweight. In fact, some lost and some gained weight. The average intake was 2140 Cal. Corrected for weight loss or gain this gave a requirement of 2215 Cal., in good agreement with the requirement of 2270 Cal. predicted from U.S. National Research Council (1953) standards (Abst. 3538, Vol. 24).—F. C. Aitken.

2227

FLOCH, H. and GÉLARD, A. Établissements de standards alimentaires adaptés aux conditions spéciales de notre Département guyanais. **[Establishment of food standards adapted to the special conditions of the Guiana Department.]** *Arch. Inst. Pasteur Guyane franç. Publ.* No. 347, December 1954, pp. 16.

The standards are founded on those proposed by the FAO Committee on Calorie Requirements (p. 517, Vol. 20) and by the U.S. National Research Council, 1948 (Abst. 4773, Vol. 18). The main difference is in taking the energy requirement of the reference woman as defined by the Committee to be 2400 instead of 2300 Cal. daily. The suggestion is made that the percentages of total energy from protein, fat and carbohydrate should be 12, 19 and 69, respectively. On these bases 12 tables are presented from which may be read the allowances of energy, Ca, Fe, vitamins A, B_1 and C and riboflavin for men, women and children, according to age and size, who live in French Guiana in a mean annual temperature of 26° C.

FEEDING OF INFANTS AND CHILDREN

2228

FANTON, E. L'allevamento del prematuro. **[Rearing of premature infants.]** *Lattante*, 1955, **26**, 88–94. [Univ. Padua.]

There is a small section on feeding which, it is considered, should be with human milk given almost continuously throughout the day and every 2 hr. at night.—E. M. Hume.

2229

OCKLITZ, H. W. Die Ernährung der Mangelgeburten mit fettreichem Nahrungsgemisch. [**Feeding of premature infants with a fat-rich food mixture.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 443–449. [Kinderklin., Univ. Rostock.]

The large number of infants born prematurely and the shortage of human milk make it desirable to find a form of nourishment that will induce the most rapid progress possible. Eighteen healthy, premature babies weighing from 1550 to 2150 g. at birth were gradually transferred when from 15 to 35 days old from human milk enriched with amino-acids to the butter, meal and full-milk mixture of Moro, containing 13 per cent. carbohydrate and 7·3 per cent. fat, and supplying 133 Cal. per 100 ml. The food was well tolerated and has since been used for more than 400 premature infants in the clinic.—E. M. Hume.

DROESE, W. and STOLLEY, H. Bemerkungen zur Arbeit von A. Sinios: "Vergleichende Untersuchungen über Ernährung mit evaporierter Milch und Sammelfrauenmilch bei jungen Säuglingen", erschienen in Z. Kinderheilk. 75, 634 (1955). [**Comments on the paper of A. Sinios: "Comparative studies of feeding young infants with evaporated milk and pooled breast milk" in *Ztschr. Kinderheilk.*,** 1955, **75,** 634.] *Ztschr. Kinderheilk.*, 1955, **77,** 48–55. [Kinderklin., Univ. Munich.]

The authors of a study comparing whole milk mixture with evaporated milk plus 5 per cent. sugar but without other carbohydrate (Abst. 986, Vol. 24) criticise the work of Sinios comparing sweetened evaporated milk with breast milk (Abst. 4030, Vol. 25) on the grounds that his population was not big or representative enough, that his range of criteria was not wide enough for a comparison of substances so different as breast milk and cow's milk, and that he left out of account the possible effects of his concentrated (2/3 or whole milk) mixtures on the immature digestive organs and kidneys of premature infants. Another point overlooked by Sinios and others is that condensed milk is a sterilised milk, which Jochims and Wilckhaus (Abst. 5079, Vol. 24) have shown to be less satisfactory than pasteurised. The authors' view is that though it is possible in case of need to rear infants on condensed milk without other addition than 5 per cent. sugar, this is not ideal, and addition of a second carbohydrate, dextrin and maltose as in the United States, or cereals as in Germany, is desirable, both to supply energy when diluted cow's milk is used and on other grounds.—W. M. Deans.

2232

SINIOS, A. Schlusswort zur Arbeit: "Vergleichende Untersuchungen über Ernährung mit evaporierter Milch und Sammelfrauenmilch bei jungen Säuglingen". [**Final remarks on the paper "Comparative studies of feeding young infants with evaporated milk and pooled breast milk".**] *Ztschr. Kinderheilk.*, 1955, **77,** 56–60. [Hamburg.]

Sinios replies to the above criticisms and includes some criticisms of the work of Droese and Stolley and two minor corrections to his original paper.

W. M. Deans.

HUGHES, B. P. **The intakes of essential amino-acids of children who were deriving most of their protein from bread and vegetables.** *Brit. J. Nutrition*, 1955, **9,** 373–378. [Dept. Exp. Med., Med. Res. Counc., Univ. Cambridge.]

Recent data on the amino-acid composition of foods are reviewed and are considered adequate for calculating the composition of diets in terms of essential amino-acids only. Values for the amounts of these in meat, fish, milk, whole wheat, patent flour, potatoes, green vegetables and pulses are tabulated. They were used to calculate the

intakes of essential amino-acids by children in 2 German orphanages (see Abst. 2560, Vol. 25) and by a group of British children (see Abst. 3602, Vol. 17) whose diet before the war was much richer in animal protein. The diets of the German children, low in animal protein, provided less of most of the essential amino-acids but, except for methionine, they provided double the minimum amounts required for N equilibrium in the adult.

WELLIN, E. **Maternal and infant feeding practices in a Peruvian village.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 889–894. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Data were obtained by interview and observation during a 4-months' dietary study of infants and of pregnant and lactating mothers in Espinos, a Peruvian coastal village. During the first 3 days the infant is not fed but is offered cotton dipped in a laxative, usually almond, oil; during this period the mother expresses and discards the colostrum and takes a laxative. Breast feeding commences after the third day; the mother suckles the infant whenever it cries but, for some days, she underfeeds at each nursing and allows unrestricted suckling only after 1 week or more. Until some time between the sixth and twelfth month, the child receives only milk with, occasionally, herb tea or sweetened water. Infants are rarely exposed to direct sunlight before the sixth month. Milk for bottle-fed babies is always boiled. During both pregnancy and lactation the mother eats less meat, eggs, fresh fruit and vegetables than usual, and drinks only small amounts of milk; the bulk of her diet consists of maize, beans, squash, rice, soups and stews and teas.

The people of Espinos tend to adjust to their particular beliefs what scientific information reaches them about foods. The result may be a worsening instead of an improvement in their diet.

HUENEMANN, R. L., COLLAZOS C., C., HEGSTED, D. M., BRAVO DE RUEDA, Y., CASTELLANOS, A., DIESELDORFF, A., ESCOBAR, M., MOSCOSO, I., WHITE, P. L. and WHITE, H. S. **Nutrition and care of young children in Peru. 4. Chacan and Vicos, rural communities in the Andes.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1121–1133. [Sch. Pub. Health, Univ. California, Berkeley.]

Studies were made of 32 children under 3 years of age living in the Andes, 13 of them in Chacan, a small farming community in the southern mountains, and 19 in Hacienda Vicos in the north. In both communities the children were breast fed until some time between the eighteenth month and the third year, with supplements of some of the family's grain, of potato soup or potatoes, sometimes cooked specially for the baby; these additions were introduced as early as the fifth month. The diets of weaned children were, like those of their families, almost entirely of grains, potatoes and other tubers, dried beans and, in Chacan but not in Vicos, turnip greens. All diets were lacking in Ca, protein, fat and, particularly in Vicos, in vitamin A; intakes of Fe and vitamins of the B group were generally high.

Other aspects of child care such as sleep, bathing, clothing, toilet training and immunisation were studied. Physical examinations showed that the children were small in size compared with Stuart's percentile ratings (Stuart and Stevenson, in "Mitchell-Nelson Text-Book of Pediatrics", 5th ed. Philadelphia, W. B. Saunders Co., 1950), and measurements of children in the Bolivian Andes (Ferrufino and Cecelino, *Bol. Soc. Boliviana Pediat.*, 1949, **3,** 18). All but 1 of the children had clinical signs of nutritional deficiencies, particularly of vitamin A.

The diets of women during pregnancy and lactation were similar to those normally eaten by the family and were deficient in the same nutrients. Some of the mothers would have altered their diets if they had had the means; others had, during lactation, used such foods as chocolate, oatmeal, tea, milk and pudding made from the white maizemeal.

The findings and those of earlier surveys in Peru are discussed. (See Absts. 1090, 2627, Vol. 25.)

WELBOURN, H. F. **Notes on differences between Baganda and Luo children in Kampala.** *East African Med. J.*, 1955, **32**, 291–298. [Child Welfare Clin., Mengo District, Uganda.]

The Luo families came from Kenya and returned for several months every year; they were less sophisticated and literate than the indigenous Baganda who lived in rural or semi-rural conditions. The Luo children, though dirtier and less well looked after, were no more prone to infection than were the Baganda children. At the age of 6 months the Luo children, especially boys, were appreciably heavier than the Baganda children and those studied up to the age of 3 years showed a continuously satisfactory gain in weight, and often were heavier than European standards. There was no difference in the incidence of signs of malnutrition between the tribes. Possible causes of the difference in the weight curve are discussed. Among the Baganda infants were usually weaned between the 12th and 14th months but among the Luo as late as the 18th to 20th month. Further, most Baganda babies needed supplementary feeding at 6 months, but the Luo babies throve on breast feeding alone for at least a year. The Baganda diet was extremely monotonous, consisting of plantain or, failing that, sweet potatoes or cassava with only a relish of beans or groundnuts. The Luo ate a good mixed diet based on a cereal staple, maize and wheat, large amounts of beans with some dried fish, meat, milk and vegetables. The possibility that racial differences account for the difference in weight is mentioned also.—L. Wills.

2242

WELBOURN, H. F. **The danger period during weaning. A study of Baganda children who were attending child welfare clinics near Kampala, Uganda. 1. 2. 3.** *J. Trop. Pediat.*, 1955, **1**, 34–46; 98–111; 161–173. [Child Welfare Clins., Mengo District, Uganda.]

1. It was desired to assess the incidence among the population of mild as well as of classical, severe kwashiorkor. A check in growth and development during weaning, which for the purpose of the study was considered to begin at the age of 6 months when supplementary feeding should be started, and signs of malnutrition, in association with dietary deficiency of protein, were considered evidence of early kwashiorkor. The general background and the methods used at the clinics are described. The mean birthweight in 2 series of 1000 single births was about 6·5 lb. and the mean length, in a small series, about 18·5 in. Most of the babies were active and vigorous at birth, sucked vigorously and appeared to be born at term. The weight and length of boys and girls at different ages were compared with United States standards for the same age groups in children of European race. Up to the age of 6 months the mean values for weight and length of both sexes were close to the 50th percentile of the standards, but from about 6 months gains in weight and length fell and by the ninth month the mean values were below the 10th percentile of the standards. The rapid gain in weight of Baganda infants in the first 3 months, which enables them to make up for their lower birthweight, occurs when the supply of breast milk is very abundant and available on demand. The lessening of growth after the sixth month results from inadequate supplementary feeding and from frequent respiratory and malarial infections. For data on individual weights see Abst. 1071, Vol. 25.

2. The customary diet of the mothers was green bananas (*matoke*) or sweet potatoes, with a relish of small quantities of groundnuts, beans or green vegetables; meat and eggs were eaten occasionally. At about 6 months supplementary feeding of the infants with *matoke* or sweet potatoes and tea prepared as for adults was begun and about a third of the mothers gave some cow's milk as well. Complete weaning was sudden and generally took place at about 15 months, when the child was frequently sent away from home. The sudden withdrawal of breast feeding seemed to have psychological effects and often caused loss of appetite. Diet surveys for 6 village children and 6 others of educated parents showed that, by League of Nations standards, intakes of protein were low, especially those of the village children. For changes found in children over 6 months of age see Abst. 2648, Vol. 25. Enlarged liver occurred only in acute malarial infection. Other deficiency states were almost never seen. Malaria was endemic, but little disturbance of general health followed infection.

3. The effects of infections, malaria and whooping-cough, and of worm infestation are discussed (see Abst. 1071, Vol. 25). It is concluded that 50 per cent. of the 780 toddlers examined showed signs of mild kwashiorkor, though only 10 severe cases were seen. The condition is considered to result from the dietary deficiency in the weaning period, exacerbated by infection. A suitable, cheap vegetable protein preparation to combat deficiency is discussed.—L. Wills.

2243

MATTHEWS, D. S. **The ethnological and medical significance of breast feeding: with special reference to the Yorubas of Nigeria.** *J. Trop. Pediat.*, 1955, **1**, 9–24. [Univ. Coll., Ibadan, Nigeria.]

Yoruba women breast feed successfully for up to 2 years. Though the upper-class babies who are weaned at about 1 year weigh more, those still on the breast appear healthy in spite of apparent undernourishment. The average length of lactation was 22 months for the first and 18 months for the second child. Most of the infants receive traditional supplements of carbohydrate food from 6 months of age. The longer the lactation, the longer the period of amenorrhoea. No instance of hyperinvolution was seen. The menopause occurs early, often before the age of 40 years. The conditions favouring successful lactation are thought to be the good development of the breasts, the women's attitude to child-bearing and -rearing which is simple and free from anxiety, early marriage, high oestrogen activity and the universal practice of breast massage during pregnancy.

The causes of failing lactation in women in Britain and New Zealand are discussed in connection with the findings for Yoruba women; the lower incidence of breast feeding in those countries is concluded to result from the failure of women to adapt themselves to changing social conditions, so that a state of stress is produced. Measures to overcome the tendency are discussed.—L. Wills.

HOLEMANS, K. and MARTIN, H. Étude de l'allaitement maternel et des habitudes alimentaires du sevrage chez les indigènes du Kwango. [**Study of breast feeding and of the nutritional habits at weaning of the natives of the Kwango.**] Addendum à l'étude de l'allaitement. Teneur en calcium et phosphore du lait de la femme indigène. [**Addendum to the study of lactation. Calcium and phosphorus content of the milk of native women.**] *Ann. Soc. belg. Méd. trop.*, 1954, **34,** 915–923; 925–927. [Clin. Maladies de l'Enfance, Univ. Liège.]

Samples, in the numbers and at the times indicated after birth, were analysed, of colostrum 19 at 2 to 4 days, transition milk 18 at 6 to 9 days and mature milk 194 at 1 to 36 months. The findings are compared with the data of Geigy-Christiaens [reference not given] for European mothers. Milk of African women had less protein, slightly more fat and much more lactose than that of European women; energy value differed little. Per 100 Cal. the African child would get only 6·2 Cal. from protein; the European would get 9·4 Cal. This relatively poorer quality of African mothers' milk is thought to be due to their poorer nutritional state, a view which receives support in the finding of a higher protein content in the milk from mothers who had received supplementary skimmed milk powder than in that of mothers with no such extra food.

Estimates of the amount of milk consumed by the African children in 24 hr. were from 323 to 417 g. below 1 year of age and, on the average, 293 g. above that age. Supplementary feeding varied greatly but generally it was rich in carbohydrate.

In the addendum data are given for Ca and P in milk; they varied widely at all stages of lactation.

L. Wills.

2245

KAYSER, K. Frauenmilchtrocknung. [**Drying of human milk.**] *Öst. Ztschr. Kinderheilk.*, 1955, **11,** 232–240. [1. Städt. Frauenklin., Erfurt.]

The history of the collection of surplus human milk and of the methods used to preserve it is briefly sketched. All methods, including freeze-drying, which failed to ensure its sterility, were rejected.

In Erfurt surplus human milk was dried to a powder in a high-vacuum apparatus. Only high quality milk from known healthy women was used. The process greatly reduced the number of micro-organisms. The milk powder was not issued for use until it had satisfactorily passed bacteriological tests. Some of the milk was first heated for 5 min. at 92° C. and some was not heated. There was some loss of vitamin C, vitamin A and carotene from the heated milk but no difference was noted in the quality of the products when they were used.—E. M. Hume.

2246

GÓMEZ LUS, R. Flora intestinal en el lactante. Composición según los distintos tipos de alimentación y modificaciones por la terapéutica antibiótica. [**The intestinal flora of the infant. Composition on different types of feeding and modifications due to antibiotics.**] *Rev. española Pediat.*, 1955, **11,** 411–442. French, English and German summaries.

The bacteriological techniques used and the criteria on which bacteria were classified are described. The infants were in 4 groups, breast-fed, partly breast-fed, artificially fed, and those receiving milk and complementary foods.

There was no significant difference which could be related to the type of feeding. There was a tendency for *Lactobacillus bifidus* to predominate in breast-fed infants, but it outnumbered *Bact. coli* in only 53 per cent. of samples from this group. In other groups *Bact. coli* predominated, especially in infants partly breast-fed. *Clostridium welchii* occurred in all groups, *Lactobacillus acidophilus* only in partly breast-fed infants. Enterococci were most common with artificial feeding. In identical twins with identical feeding the flora differed widely.

Penicillin given parenterally affected the intestinal flora, but streptomycin had little effect except

when given by mouth. Terramycin was especially effective in reducing the numbers of bacteria. The re-establishment of a normal flora after treatment with antibiotics is discussed.—D. Duncan.

2247

MÖSSMER, E. Viehfutter - Milch - Kind. [**Cattle food, milk and child.**] *Münch. med. Wochenschr.*, 1955, **97**, 1276. [Säuglings- und Kleinkinderkrankenhaus, Landshut.]

The author gives his impressions, after 40 years' experience, of the effects that the different kinds of food eaten by the cow have on its milk at different seasons, and on the infant fed on its milk. He considers the matter of considerable importance. For instance, many babies refuse the milk at the season when beet leaves are given, and certain mountain hays, given only in times of shortage, are regarded as actually poisonous.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

2248

CHAPPELL, G. M. **Long-term individual dietary surveys.** *Brit. J. Nutrition*, 1955, **9**, 323–339. [Dept. Household Sci., Queen Elizabeth Coll., Univ. London.]

There were 2 subjects, one a woman whose duties were assessed as requiring less than moderate activity and the other a retired man thought to be more active than a sedentary man. For the first subject the survey was in 2 parts of 61 and 9 weeks' duration with an interval between them of 13 weeks; for the second the survey lasted 13 weeks. Mean daily intakes were calculated from food tables. In the following order of nutrients and units, total protein, animal protein, fat and carbohydrate in g., Ca, Fe, vitamin B_1, riboflavin, nicotinic acid and vitamin C in mg., vitamins A and D in I.U. and the number of Cal., the means for the first subject were 65·8, 34·1, 87·7 and 305·8; 1078, 12·8, 1·19, 1·60, 10·08 and 146; 2827 and 189; and 2275. For the second subject the means were 98·9, 53·8, 121·1 and 400·6; 1425, 15·79, 1·64, 1·86, 13·14 and 104; 3100 and 215; and 3089. Mean percentages of calories from fat, carbohydrate and protein, respectively, were, for the first, 34·7, 53·8 and 11·6 and, for the second subject, 35·2, 51·9 and 12·8.

Statistical analyses were made by methods to be described later (Church and Lipton, *Brit. J. Nutrition*, 1956, in the press). In the first survey standard errors for the means were between 8 and 15 per cent. except for vitamins A and C, 24 per cent., and vitamin D, 75 per cent.; in the second they were between 7 and 17 per cent. except for vitamin D, 76 per cent. The analyses showed also that an estimate obtained from a number of 1-week periods systematically distributed over a year was more accurate than one from a single sampling period of the same duration. An estimate of intake of a nutrient with a standard error of 5 per cent. would be provided by three 1-week periods at intervals of 4 months or by two 2-week periods with an interval of 6 months; a single period of as long as 12 weeks would not provide so accurate an estimate.—D. Harvey.

2249

MINISTRY OF FOOD. **Domestic food consumption and expenditure, 1953. Annual report of the National Food Survey Committee.** H.M.S.O., London, 1955, pp. 104. Price 4s. net.

For the 1952 report see Abst. 1081, Vol. 25. As additional features the present one includes a section on Scottish diets and a discussion of the difftences between urban and rural households. The total number of households was 11,395 and of persons 36,756.

During the year restrictions became fewer and the amount of meat eaten increased at the expense of fish. There were increases also in amounts of cheese, eggs, butter, sugar and fruit, but the amounts of cereal products and potatoes were less than in 1952.

The total value of consumption was 23s. 7d. and expenditure on food was 22s. 8d. per head weekly. The increase of 2s. 1d. over the 1952 amount was almost all on carcase meat, eggs, butter, tea, bacon and sugar. The use of white as distinct from national bread was small. Changes in and the final cessation of rationing of sugar were followed by an increase to 13·57 oz. per head weekly from the level of 11·00 oz. in 1952. There were, in general, increases also in nutrients over the 1952 amounts, except for Ca and vitamin C, which did not alter, and for vitamin D, which fell. Against the British Medical Association standards, intakes were adequate. There was a small reduction of energy from protein and carbohydrate and a slight increase of that from fat. Sweets, at 8·1 oz. per head weekly, provided 150 Cal. daily. Persons in rural households were 21·6 per cent. of the total. They differed from the urban group in eating more bread and flour, milk, cheese, eggs, fresh green vegetables and preserves, less potatoes and other vegetables and much less fish. Their intakes of Ca, carbohydrate and vegetable protein were greater because of these larger amounts of bread and flour.

After a re-assessment of incomes new levels were chosen for the social classes, Class A over £15, Class B £9 to £15, Class C £6 to £9 and Class D under £6. With these new grades the proportions of the population in the groups were 6, 23, 40 and 31 per cent. and the values of consumption 28s.

7d., 24s. 4d., 23s. 1d. and 22s. 9d., respectively. For the Old Age Pensioner (OAP) group it was 21s. 6d. Levels of nutrients were lowest in many cases in Class C in which the proportion of children was highest. Except for Fe in the diet of the OAP group all intakes exceeded 95 per cent. of the recommended amounts.

Family composition was much more important than social class in deciding type of diet. More was spent on food than in 1952, the average being 62s. 9d. for a household of 2 adults, both under 55 years of age and without children; the amount for the addition of each child was 8s. 6d. Least satisfactory were the diets in households with 3 or more children or with adolescents and children; such households tended to rely more than in previous years on welfare and school schemes for their milk supplies.

The analysis of Scottish data was for 1172 households with 4186 persons and an average weekly expenditure of 22s. 3d. per head. In comparison with the rest of the country the extreme differences in foods were for cakes and pastries 50 per cent. more eaten and for fresh green vegetables 66 per cent. less, but, on the average, deviations from recommended amounts of nutrients were similar to those found for Britain as a whole.—D. Harvey.

2250

[Ministerie Landbouw, Visserij en Voedselvoorziening]. De voeding in Nederland. [**Diet in The Netherlands.**] *Voeding*, 1955, **16**, 900–923. English summary.

Diet here means consumption estimated as closely as may be from statistics of supplies entering trade with estimates for consumption by self-suppliers. Pre-war data for 1936–38 have been revised and re-computed on the same basis as post-war and estimates for riboflavin and nicotinic acid have been added. The data in terms of foods, gross and per head, and of energy, protein (animal and plant), fat, carbohydrate, Ca, P, Fe, vitamin A, carotene, vitamin B_1, riboflavin, nicotinic acid and ascorbic acid are presented in 19 tables, covering the average for 1936–38 and the years 1947 to 1954 separately. Compared with 1936–38 the supplies of energy, animal protein, Ca, vitamin A and riboflavin have increased; that of nicotinic acid has fallen slightly. The rise in fat is explained as increase in consumption of margarine and that in vitamin A as the result of compulsory addition to margarine. Improved milk supply explains the rises in Ca and riboflavin.—I. Leitch.

2251

Mulder, T. Uitkomsten Nationaal Budgetonderzoek 1951. [**Results of the National Budget Survey, 1951.**] *Voeding*, 1955, **16**, 880–884.

Brief accounts are given of the expenditures on foods in certain general groups and amounts purchased of these foods by manual workers, analysed by income and size of family; expenditure of middle-class industrial and clerical workers, by place of residence and size of family, and expenditure and purchases of professional workers, by income and size of family; expenditure of families with pensioned members, by income and residence; consumption of families on relief and pensioned. The amounts of self-supplied foods are shown separately. See also Abst. 4043, Vol. 25.

I. Leitch.

Swaak, A. J. Onderzoek naar de voeding en voedingsgewoonten bij meisjes van 14–23 jaar in Maastricht en omgeving. [**Diet and dietary habits of girls from 14 to 23 years old in Maastricht and district.**] *Voeding*, 1955, **16**, 956–976. [Gemeent. Geneesk. Dienst, Maastricht.] English summary.

The subjects were 233 girls of whom 105 were students at a school of domestic science, 50 factory girls, 39 office girls of whom 5 were shop assistants, and 39 in diverse occupations. The study was made by the students. A daily record was kept of food eaten for a week and during that week the girls were weighed and measured, Hb was estimated and age at menarche recorded. For the students, a more detailed clinical examination was made for "subclinical signs of deficiency". The results are presented in detail, the clinical signs "with much reserve", with an analysis of eating habits.

Menus were analysed in terms of the standards set up by Dols and den Hartog (Abst. 1022, Vol. 24) and were sub-standard in milk, milk products and vegetables. Diets were correspondingly low in carbohydrate, Ca, vitamin B_1, riboflavin and nicotinic acid. By the Sahli method 18 per cent. of the factory girls were judged anaemic, with Hb below 12·5 g. per 100 ml., but on the average Fe intake was adequate. Office girls were taller and heavier than factory girls. The signs of deficiency included bad teeth, folliculosis, gingivitis, dry hair and abnormalities of the tongue.—I. Leitch.

Freiberg, D. Lebensstandard und Ernährung. [**Standard of living and diet.**] *Lebensmittel u. Ernährung*, 1955, **8**, No. 10, 7–8.

This article is mainly a resumé of a study of food consumption in 4 large cities of the United States in 1949 [reference not given but apparently to work in Abst. 5510, Vol. 25] but includes a statement based on preliminary findings of a study of household budgets in Austria in 1954 that about half the money goes for food, from 47·6 per cent. in Vienna to 55·9 per cent. in Feldkirch.—W. M. Deans.

2254

WOODHILL, J. M., VAN DEN BERG, A. S., BURKE, B. S. and STARE, F. J. **Nutrition studies of pregnant Australian women.** *Amer. J. Obstet. Gynecol.*, 1955, **70**, 987–1003. [Dept. Maternal and Child Health, Harvard Sch. Pub. Health, Boston, Mass.]

The first part deals with the occurrence of toxaemia and the condition of their infants among 52 primigravidae and 134 multigravidae attending the antenatal clinic of a Sydney hospital. " Cases were selected for interview on the basis of obstetrical examination that gave no indication of abnormality ", but a history of pre-eclampsia was not a cause of exclusion. Most of the husbands earned more than the current basic minimum wage. Diet histories relating to the pre-pregnant period and to the first and second halves of pregnancy were obtained, analysed and evaluated by the Burke procedures; they have already been reported in Abst. 2132, Vol. 23. On the average, 61 women had excellent or good, 62 had fair and 52 had poor or very poor diets. In 11 cases the diets could not be evaluated for all 3 periods owing to abortion or vomiting. The incidence of toxaemia ranged from 42 per cent. in women with very poor diets to 5·6 per cent. in those with excellent diets. The incidence was high in obese women, but no relation could be demonstrated to excessive weight gain during pregnancy. The incidence of prematurity increased as diets during pregnancy became worse, but there was no relation to pre-pregnant diets; similarly, average birthweights were related to the diet ratings.

The second part deals with the lactations of the same women. The better the average diet, the greater the proportion of women who succeeded in breast feeding for any given period. Early weaning was associated with obesity before pregnancy but not with excessive weight gain during pregnancy.—A. M. Thomson.

2255

DUBAR, I. G. **Analysis of food dollar in a children's home.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1147–1149. [Texas Sch. for the Blind, Austin.]

A 7-day survey by the inventory method was made of food consumed in 6 cottages housing 173 blind children. Intakes of food groups, their proportionate costs and contributions of nutrients are shown.—F. C. Aitken.

WARNICK, K. P., BRING, S. V. and WOODS, E. **Nutritional status of adolescent Idaho children. 2. Food habits.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1143–1146. [Dept. Home Econ. Res., Univ. Idaho, Moscow.]

The results of a diet survey, previously analysed in terms of nutrients (Abst. 5505, Vol. 25) are presented in terms of food groups. Meal patterns and daily consumption are shown.—F. C. Aitken.

2257

ODLAND, L. M., PAGE, L. and GUILD, L. P. **Nutrient intakes and food habits of Montana students.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1134–1142. [Dept. Home Econ. Res., Montana Agric. Exp. Stat., Bozeman.]

Studies were made of diet and food habits of 418 students born and reared in Montana and in good health; 221 aged 15 years were from the Bozeman and Great Falls area; 197 aged from 16 to 28 years were from other localities in the state. Data were obtained over a year on the foods generally consumed and details were recorded over a 7-day period of the foods actually eaten.

The mean daily intakes by all the women students, 111 in the first and 100 in the second group, exceeded two-thirds of the amounts recommended by the U.S. National Research Council (Abst. 3538, Vol. 24); for men the intakes generally exceeded the recommended amounts. Within sex groups there were only minor differences in average intake between the adolescent and the older students. The adolescents in the 2 areas consumed diets similar in composition except for ascorbic acid content, the intake of which was related to seasonal variation in fruit supplies. Of the women, 78 per cent. ate diets which provided less than two-thirds of the allowance of one or more nutrients; one-third had diets below this level in only one nutrient, namely, Fe, Ca or ascorbic acid; if two or more nutrients were below two-thirds of the recommended amounts the common deficiencies were of Ca in combination with Fe, vitamin B_1, riboflavin and/or ascorbic acid. Of the men, about 40 per cent. had less than two-thirds of the amounts of one or more of the recommended nutrients; half had diets low in only one nutrient, usually ascorbic acid; in diets in which more than one nutrient was low in amount the deficiencies were generally of Ca and energy, vitamin B_1, riboflavin and/or ascorbic acid.

The students ate relatively small amounts of leafy, green, and yellow vegetables, tomatoes and citrus fruit, eggs, potatoes and sweet potatoes and relatively large amounts of meat, fish, poultry and other fruits and vegetables. Forty per cent. of the breakfasts of men and 30 per cent. of those of women students were adequate, as judged by inclusion of a fruit, a cereal and an animal protein food. There was a direct relation between the number of such breakfasts and the number of subjects for whom the mean daily nutrient intake provided at least two-thirds of the recommended allowance of any nutrient.—G. F. Garton.

2258

FLOCH, H. and LECUILLER, A. Enquête sur la consommation alimentaire réelle et la valeur alimentaire de la ration guyanaise. [**Inquiry on actual food consumption and the food value of the diet in Guiana.**] 2. Discussion. [**2. Discussion.**] 3. Analyses de produits alimentaires guyanais. [**3. Analyses of food products of Guiana.**] *Arch. Inst. Pasteur Guyane Publ.* No. 277, January 1953, pp. 10; *Publ.* No. 285, June 1953, pp. 8; *Publ.* No. 286, June 1953, pp. 6.

1. The mean values for each of 100 diet studies in orphanages, a barracks and family homes are tabulated in terms of animal and vegetable proteins, animal and vegetable fats, carbohydrates and energy, together with the ratios of some of these. The number of persons concerned was 914, 512 adults and 402 children. The conclusions were that for about 40 per cent. of them the intake of energy and for from 45 to 50 per cent. the intake of food from animal sources was low.

2. The foodstuffs which the survey showed to be in use are listed and specimen menus for the 3 meals in a day are given. Prices for fresh vegetables are quoted in explanation of the small extent to which they are used.

3. Brief descriptions of some of the foods are given with data for energy-yielding and ash constituents of 13 and for vitamin C content of 26. (See also Absts. 1819, 1820, Vol. 26.)—D. Harvey.

2259

STRAUSS, W. (with SHATAN-HERZBERG, M., RIM, J. and ZAITSCHEK, D. V.) **A preliminary investigation into the food habits of Oriental Jewish communities with special reference to the changes enforced by immigration to Israel.** June 1955, pp. 19. [Dept. Hyg., Hebrew Univ. Med. Sch., Jerusalem.]

By the interview method information was obtained from 42 families who had lived in Israel for at least 3 years; their countries of origin and numbers were Iraq 11, Morocco 12, Yemen 9 and Aden 10. Menus for week-days and sabbath are fully described. The particular problems facing the separate groups were that the range of foods was narrower than in Iraq, cooking oil was scarcer than in Morocco, spices and peppers were in even greater demand and were more expensive than in Yemen; in contrast, the Aden community, which continues to receive parcels of food from its source, has become better adapted to the new conditions.

It is recommended that measurements of height, weight and Hb of some or all immigrants should be made at the time of arrival, that teaching of nutrition should reach a greater proportion of the immigrant housewives, that supplies of certain habitual foods such as rice, vegetables and spices be increased and the use of fresh milk encouraged.—D. Harvey.

CHAUDHURI, S. **Haematological indices in an average Indian population and their correlation to the nutritive states and plasma proteins.** *J. Trop. Med. Hyg.*, 1955, **58**, 264–269. [Haematol. Res. Lab., Safdar Jang Annexe Hosp., New Delhi.]

The subjects, numbering 450, were in 4 groups with subdivisions and, in brackets, numbers as follows: (1) from the better classes, women, nursing and medical students (156), and men, clerks or orderlies in civil (15) and in military (20) hospitals; (2) children, urban in age groups 0 to 1, 1 to 4, 5 to 8 and 9 to 14 years (20, 7, 23, 30) and rural in the same age groups (0, 10, 5, 7); (3) pregnant women at a maternity centre in the town (25) and in the country (26); (4) families, urban (35 adults), rural (58 adults) and in slums on the city boundary (13 adults). Individual dietary surveys were made for subjects in the first 3 groups except for the babies under 1 year who were breast fed; for the families in group 4 a mean value for intake was calculated from the total intake of food. Blood samples were from a vein during fasting. The following data are tabulated: daily intakes of foods per head for group 4 families, ranges and means for intakes of protein, carbohydrate, fat and energy for rural and slum families and for subjects in group 3, means for daily intakes of energy and protein, bodyweight, total protein, albumin and globulin in plasma and red cell count, Hb, haematocrit, mean cell volume and mean corpuscular Hb concentration for each group as subdivided.

The main findings were: protein and energy were low in all diets other than those of military hospital staff; protein from animal sources was small in amount; a direct relation seemed to exist between diet and plasma proteins, especially albumin; a sex difference in favour of males was noted for intakes of energy and protein, level of plasma protein, red cell count, Hb and haematocrit; even when total protein in plasma was normal, albumin tended to be below and globulin above "accepted textbook normals for adults".

D. Harvey.

2261

SHARMA, D. C. **Mother, child and nutrition.** *J. Trop. Pediat.*, 1955, **1**, 47–53. [Devi's Child. Clin., Mandala, Burma.]

The conclusions are based on a clinical and field study. Burma is self-sufficient in food supply but, among the masses and particularly the Burmese, malnutrition is very frequent because of food prejudices and superstition. Prejudice is especially strong during pregnancy and lactation, when the

diet of the Burmese women is mainly of polished rice with very small amounts of fish and oil and occasionally small helpings of mutton or pulses; for various reasons, eggs, milk, sugar, vegetables and fruit are excluded. In the villages and among the poorer classes in the towns beriberi is common among Burmese women and infants but is not seen in the other races. In the mothers it is normally of the dry type and of gradual onset. In the infants signs appear often as early as the third or fourth week of life and death may be sudden. In one family several children may have been lost at an early age. Vitamin B_1 given by injection generally cures both mothers and infants and change to a suitable diet allows the mother to continue breast feeding with excellent results. Cases are quoted in illustration.—L. Wills.

INTENGAN, C. L., DEL ROSARIO, I., ARZAGA, V. L., CONCEPCION, I., SALUD, R. D. and MANALO, J. D. **Nutritional evaluation of meals served in government institutions by chemical methods.** *Philippine J. Sci.*, 1954, **83**, 177–186. [Foods and Nutrit. Biochem. Lab., Inst. Nutrit., Manila.]

A survey was made of the diets served in 9 government institutions to children, convalescents, moderately active adults and very active adults. A tray was selected at random for each of the 3 meals for 3 mid-week days. Snacks and drinks between meals were included. In all, 144 meals were analysed. Rice was the basis of the diets. Values for nutrients including carotene were obtained by analysis; those for vitamin A were from food tables. Intakes were compared with the daily allowances recommended by the National Research Council of the Philippines as modified by the Institute of Nutrition. The amounts of vitamin B_1, vitamin C and Ca tended to be inadequate, but vitamin A and riboflavin were the nutrients which most often were truly insufficient. Increased consumption is recommended of foods rich in vitamin C, green and yellow vegetables, nuts and seeds, and enriched rice.—E. M. Hume.

FACHMANN, W., HAHN, E., KRAUT, H., MELLINGHOFF, K., OBERDISSE, K., SOUCI, S. W., WIRTHS, W. and ZACHARIAS, R. Berichte über Studienreisen im Rahmen der Auslandshilfe der USA. Mehr Wissen um Ernährung. [**Reports of study journeys under the auspices of the Foreign Aid Program of the U.S.A. More knowledge about nutrition.**] *AID, Land- u. Hauswirtschaft. Auswertungs- u. Informationsdienst*, 1955, No. 74, pp. 118. [Verlag Kommentator G.m.b.H., Frankfurt a.M.]

The first 90 pages of this report, compiled by Professor Kraut and Dr. Wirths of the *Max Planck Institut für Arbeitsphysiologie*, describe, with illustrations, food and nutrition arrangements in the United States as seen by the 8 Germans in a party of 28 from 8 European countries during a 3-months' tour under the auspices of the Foreign Aid Program in the spring of 1953. The itinerary extended from Washington, D.C., Philadelphia and several other places in Pennsylvania to Chicago and as far west as Minneapolis and St. Paul, Rochester, Minn., and Kansas City, Mo. After a brief sketch of agriculture in the U.S., successive chapters deal with the transfer of foods from producer to consumer, eating habits in the home and outside, with tables of foods consumed annually per head, nutrition surveys, school lunches, hospital feeding, and measures to improve nutrition still further by research, education of schoolchildren and the general public, and special plans for vulnerable groups of the population.

In the rest of the report, proposals inspired by experiences in the U.S. for improving nutrition in the different economic, psychological and educational conditions of West Germany are set forth and discussed. These include the following: increasing the consumption of fruit and fruit juices; increasing the amount of milk drunk, which would necessitate improving its quality; improving the food in hospitals, convalescent homes and communal feeding places; trials of the cafeteria system; improved food laws and market information; instruction in nutrition in schools of all kinds, and for teachers in training and medical and other students; dietitians' training to be extended to cover large-scale catering for the healthy; training of nutrition advisers; instruction of the healthy adult; provision of milk and perhaps fruit in schools; special measures for vulnerable groups, including the elderly; establishment of diet clinics in hospitals; medical support for the existing lay society of diabetics; establishment of metabolic clinics; bringing up to date of tables of food composition and methods of analysis; coordination of nutrition research with that of other countries, by exchange of literature and otherwise, and finally, formation of a non-official German Nutrition Society (since achieved).—W. M. Deans.

2265

DE CASTRO, J., BARBOSA, J. J. and SANTOS, W. Relatório do Brasil à 3.ª Conferência Latino-Americana de Nutrição 1953. [**Report on Brazil to the 3rd Latin-American Conference on Nutrition 1953.**] *Arq. brasil. Nutrição*, 1954, **10**, 9–43.

The problems of undernutrition and malnutrition in Brazil have been aggravated by a rapid development of industry at the expense of agriculture, and by concentration of the population in the industrial areas. The government recognises that the poor health of the people has a socio-economic origin, and it has taken vigorous steps to improve the situation.

Measures in force are described. Mechanisation of agriculture, increased production of food from the land and improvement of stock are given every assistance and encouragement, and finance for agricultural development by co-operation has been organised. Production and distribution of food are controlled.

Committees on nutrition have been formed which, after detailed investigation of the state of nutrition and health of the people, have set up canteens and restaurants for workers and students. School lunches are given in an increasing number of places. Foods are enriched with iron to combat the widespread anaemia, and iodised salt in areas of endemic goitre. Special consideration is given in the nutrition programme to pregnant women and to children. Medical examinations of many classes of the population are made, and treatment is given for specific illnesses when necessary.

A scheme is now in operation for training the social workers, technicians and scientists needed to extend the work.—T. D. Bell.

2266

FLOCH, H. Étude du problème de l'alimentation en Guyane française. [**Study of the problem of diet in French Guiana.**] *Arch. Inst. Pasteur Guyane Publ.* No. 298, October, 1953, pp. 7.

The population and resources of French Guiana are briefly summarised. Foodstuffs of animal origin are scarce; fresh milk is almost unobtainable. The principal vegetable foods are dried legumes, rice and "couac", a preparation from *Jatropha manihot*; the common fruit is banana, and few others are cultivated. Reference is made to diet studies and to the administration of yeast to children. (See Absts. 2239, 2258, Vol. 26.)

D. Harvey.

FLOCH, H. and GÉLARD, A. Sur quelques points touchant l'alimentation-nutrition en Guyane française ayant des possibilités d'amélioration rapide. [**Some points on feeding and nutrition in French Guiana where there are possibilities of rapid improvement.**] *Arch. Inst. Pasteur Guyane franç. Publ.* No. 358, April 1955, pp. 6.

Three possible lines of action are considered: (1) cultivation of the round cherry, *Malpighia punicifolia*, as a source of vitamin C, of the palm *Astrocaryum vulgare* for carotene and of the guava for carotene, nicotinic acid and vitamin C; (2) encouragement of the growing of fresh green vegetables, in which difficulties are mainly cultural and result from erosion, heavy rainfall or pests such as the ant (*Atta sexdens*) or crickets; (3) development of a fishing industry, for the products of which transport markets would need to be organised. (See also preceding Abstract.)—D. Harvey.

LANGER, A. and HENSHAW, P. S. **The interacting effects of public health, fertility behaviour and general economy on standards of living. 2. Qualitative evaluation of factors responsible for conditions in countries with similar situations.** *Amer. J. Med. Sci.*, 1955, **230**, 484–490; 519. [Nat. Committee on Maternal Health, Inc., 2 East 103rd St., New York 29.]

Interlingua summary.

Birth rate, death rate and other basic data as well as calculated indices of total fertility, population pressure, degree of economic development and the "situation index" defined earlier (Abst. 965, Vol. 26) are grouped into 5 ranges and tabulated for 70 countries. In a second table, countries are graded according to the severity of their problems of total fertility, population pressure and economic development. This reveals the particular conditions responsible for a high overall "situation index" and enables prediction of the probable ultimate effect on standard of living of, *e.g.*, health measures, though the accuracy of such predictions of course cannot exceed that of the basic data or the assumptions made.—W. M. Deans.

2270

KEYS, A., ANDERSON, J. T. and BROZEK, J. **Weight gain from simple overeating. 1. Character of the tissue gained.** *Metabolism*, 1955, **4**, 427–432. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

Twenty men were induced to overeat for 6 months with constant activity. Mean weight gain was 10·6 kg. The tissue mass gained was

estimated to be 13 to 15 per cent. extracellular fluid, 61 to 64 per cent. fat, 0 to 1 per cent. glycogen and the remainder cells. The composition of the tissue was independent of the weight gained over the range 2·5 to 22·3 kg. The percentage of cells was lower, and that of fat higher, than was previously estimated in tissue gained by men re-fed after prolonged severe undernutrition.

2272

PACI, C. Latte e riso binomio perfetto. [**Milk and rice : a perfect pair.**] *Riv. Zootec.*, 1955, **28**, 255–259.

Rice and milk are complementary, the one supplying essential amino-acids and vitamins which the other lacks ; together they are almost a complete food. Unfortunately the production and distribution of neither is controlled, and more often than not they appear on the market in poor quality. This is one reason for their lack of popularity and, in the circumstances, propaganda to increase consumption of either is useless. Essential to increased consumption are an all-round improvement in quality, some reduction in price and education in milling, use and cooking of rice.

T. D. Bell.

2273

MOQUAY, M. Utilisation alimentaire de la couenne. [**Alimentary uses of pork rind.**] *Thesis, Paris*, 1954, pp. 58.

Analytical data are given for the composition of pork rind and for the moisture it takes up when cooked. The nutritive value was studied with groups of rats. When added in its crude form and containing from 16 to 20 per cent. fat, pork rind improved the rate of growth over that of a group of rats on the basal diet of cereals. When, after extraction of the fat, it was included at a high level in their diet, the rats lost weight rapidly in the same way as has been reported for rats given an incomplete protein such as gelatine.

The preparation of jellies from pork rind and the methods and legal control of the use of the rind itself in the pork butchery trade are described and discussed.—D. Harvey.

2274

SERGENT, G. Une solution immédiate à la malnutrition de l'Africain : la récupération du sang de boeuf. [**An immediate solution for the malnutrition of the African : recovery of ox blood.**] *Bull. Acad. vét.*, 1955, **28**, 183–187 (with discussion 187–188). [Centre Prélèvements Biol., Paris.]

It is calculated that about 2,500,000 litres of ox plasma could be collected annually from slaughterhouses in Paris alone. Dried or fresh plasma and red cells have been eaten in many ways in European diets in times of stress. The food value of blood products, especially as sources of protein, is high. The preparation of dehydrated products for export to Africa is suggested as a means of combating the lack of protein prevalent in French African territories.—A. M. Copping.

2275

FRANKE, K. Sport und neuzeitliche Ernährungspraxis. [**Sport and modern nutrition practice.**] *Deutsch. med. Wochenschr.*, 1955, **80**, 1813–1814. [Bad Lauterberg.]

After a discussion of the needs of different types of athletes, the following recommendations are made : not too much to eat, and especially not too much fat ; part replacement of meat by milk products (curds, cheese, milk beverages and sour milk) and whole grain cereals ; fruit and salads instead of soup ; fat mainly as butter or as vegetable oils or high-grade margarine containing the essential unsaturated fatty acids ; mild herb or yeast flavourings rather than too much salt and pepper ; and for young people, fruit juice and milk beverages instead of tobacco, alcohol, coffee and kola.—W. M. Deans.

2276

FILHO, W. L. Rações de campanha e de reserva na aeronáutica. [**Field and reserve rations in the Air Force.**] *Arq. brasil. Nutrição*, 1954, **10**, 207–224.

There is a discussion of the research and experience of the U.S. Air Force, during and since the second world war, in planning rations suitable in both composition and form for the needs of flyers. On the basis of that information 3 types of ration have been prepared for the Brazilian Air Force. One is a package providing about 500 Cal. in the form of vitamin chocolate, chewing-gum and sweets and designed to maintain efficiency during short operations. The second, of which there are 5 variants, is a packed meal for longer bombing or patrol missions ; it contains a meat dish, sweets, biscuits and materials for preparing coffee, and provides about 1200 Cal. The third is an emergency ration in concentrated form and supplies 500 Cal. ; with it are packed Dramamine, cigarettes, matches and a water distiller.

BELLOMO, A. Considerazioni sull'alimentazione nella vecchiaia. [**Considerations on diet in old age.**] *Acta gerontol.*, 1955, **5**, 250–255. [Div. Med. Geriat., Osp. Maggiore, Turin.] French and English summaries.

A plea for commonsense in the application of theoretical considerations to the diet of the elderly. Too rigid adherence to principles suggested by experimental work, *e.g.*, restriction of animal protein, bread and eggs in subjects with a tendency to high blood pressure, may lead to deficient and unattractive diets which will not promote wellbeing. The fixed habits of a lifetime must be considered also, and it is seldom necessary to forbid moderate use of alcohol or coffee.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

2279

HAMMOND, W. H. **Measurement and interpretation of subcutaneous fat, with norms for children and young adult males.** *Brit. J. Prev. Social Med.*, 1955, **9**, 201–211. [Minist. Health, London.]

Skin-fold thickness was measured with the Medical Research Council callipers and also with the modified Franzen callipers (Abst. 5545, Vol. 25). Joint trials were made by 3 observers to ensure that their standards were comparable. The subjects, just over 4500 in number, were in 6 groups including ages from infants to adult women, different social classes and a group of debilitated children.

Measurements from 16 different sites were well correlated; correlations between single sites and total fat were of the order 0·8 to 0·9; 2 sites usually gave multiple correlations of the order of 0·95, and 3 sites 0·97 or better.

Sub-scapular and abdominal measurements followed by biceps and either sub-costal or supra-iliac measurements gave the best indication of total fat. In 2 studies on children the changes at 5 or 6 different sites were followed for 24 months. It was found to be more important in such studies to use several sites. The 6 sites finally selected were biceps, triceps, sub-scapular, supra-iliac, subcostal and abdominal (umbilical region).

Age trends at the different sites are tabulated for both sexes and ages from 2 years upwards. In girls there was a slight decrease in fat on all sites from 2 to about 5 years, then a continuous increase to 15 years, when the data stop. In boys the trunk fat decreased from 2 to 7 years, then increased rapidly to 11 years and more slowly to 17. The arm fat in boys decreased until 8 years, rose slowly to 11 and then fell, first slowly and then steeply, to 18 years of age.

A scatter diagram shows the relation between calliper measurements and measurements of subcutaneous fat thickness from X-ray photographs. Correlations were from 0·82 to 0·90, depending on site and sex.

Mean measurements for different nutritional and social groups descended from good to poor nutrition and from high to low social class, but there was no social gradient in body fat comparable with those in height and weight.—D. Duncan.

Clinical and biochemical observations made in the years 1949 to 1953 on 320 infants with so-called alimentary intoxication are discussed. About half the infants failed to show all the classical signs of the disorder, but a low alkali reserve in the blood serum (below 30 vol. per cent.) was almost invariably found, and this is considered the most reliable diagnostic sign. In a few, low blood chloride was found instead, in others it was high or normal; these differences were not related to diarrhoea and vomiting or to the origin of the disorder, which was parenteral in 74, digestive disturbance at weaning in 29 and enteral infection in 211, the other 6 being premature infants with severe *icterus neonatorum*. Of the 211 with disorder originating in the digestive tract, 80 were already marasmic and 34 others were premature. Of the 320, 264, over 80 per cent., were under 3 months of age. In contrast to former times, there was no distinct peak of incidence in the summer months. Deaths in the first 36 hr. are diminishing owing to the use of antibiotics, especially chloromycetin.—W. M. Deans.

WUNDERLICH, C. Zur Frage cerebraler Schäden infolge Atrophie im Säuglingsalter. **[The problem of brain damage as the result of marasmus in infancy.]** *Ann. paediat.*, 1955, **185**, 193–211. [Kinderklin., Univ. Mainz.] English and French summaries.

This is an amplification of a paper given at the *Deutscher Kinderärztekongress*, Essen, 1954 (see *Mschr. Kinderheilk.*, 1955, **103**, 167), a follow-up study at 4 years of 56 [or 54] marasmic infants. Excluded were children with birthweight under 2500 g., those with suspected congenital or acquired brain damage, those with some underlying disorder, *e.g.*, fibrosis of the pancreas, and those in whom marasmus had followed acute intoxication. It was found that subsequent development depended less on the degree of duration of marasmus than on its causes and in particular on the goodness or badness of the economic and psychological environment. The 36 with a good background had more than caught up in height, but not the 18 with a poor background, though in weight for height they were not inferior. The former group walked and talked earlier and did better in the Bühler Hetzer mental test. The marasmic children with a poor background generally showed signs of neglect and poor feeding (either prolonged underfeeding, or senseless overfeeding, or dietary errors); many had had no vegetables or fruit for months or even years. Signs of vitamin C deficiency and rickets were common. Since these conditions were frequently found again at the follow-up, it was thought that they had more to do with the poor development of these children than the actual marasmus. Familial mental defect or disorder was not uncommon. Among children with a good background, marasmus generally resulted from other illness and although 8 of them showed brain disorder either at the outset or at follow-up, in at least 2 of these the connection with marasmus was not clear.

Findings for marasmic children do not necessarily apply to adults who have had hunger dystrophy.—W. M. Deans.

ZUIDEMA, P. J. **Calcification and cirrhosis of the pancreas in patients with deficient nutrition.** *Doc. Med. geogr. trop.*, 1955, **7**, 229–251. [Bethesda Hosp. and Internal Dept., Gadjah Mada Univ., Jogjakarta, Indonesia.]

A comprehensive review of the literature is given. In the cases previously reported, largely European or American, pancreatic lithiasis has been a disease chiefly of middle-aged males and thought to be a late complication of chronic

pancreatitis. Pain is a constant feature, and often there is a history of alcoholism. Steatorrhoea occurs in about 25 per cent. and diabetes mellitus in from 25 to 40 per cent., the latter being a late complication.

In the present study 7 patients, 4 male and 3 female, were aged from 15 to 28 years. Six, all seen in 1 year, attended as severe cases of diabetes. All of them were undernourished, none complained of abdominal pain, none gave a history of alcoholism and there was no suggestion of earlier pancreatitis; steatorrhoea and undigested muscle fibres were absent. In 2 patients the parotid glands were greatly enlarged. In some the diabetes was insulin-resistant. The patient who did not have diabetes complained of severe pain in the epigastrium and right upper abdomen. X-ray examination showed displacement of the duodenal loop and a large deposit of calcium towards its centre. Pancreatic calcification, which was generally disseminated, was diagnosed by X-ray examination in all but one patient, in whom it was found later at post-mortem examination; it was then established that the calcification was associated with marked fibrosis and early cirrhosis of the liver with fatty infiltration. Other diabetic patients with similar histories and general undernutrition were admitted, but X-ray examination did not reveal calcification of the pancreas. In samples of duodenal juice from 3 patients with and 6 without calcification the enzyme concentration was, in general, low.

These cases differ so markedly from those previously reported that the etiology is almost certainly distinct. The occurrence of the same picture in patients with no evidence of calcification and in others with varying degrees of calcification suggests that the process is terminal to some other condition, probably interstitial fibrosis associated with changes in the parenchyma. The patients came from low economic and social groups and the nature of their diet, low in energy and in animal protein, suggests that protein deficiency was important etiologically. The presence of signs of malnutrition in most of the patients, and the known relation between protein deficiency and pancreatic damage in kwashiorkor, support the theory of a dietary origin.—L. Wills.

SUBRAHMANYESWARA RAO, T. T. V. **The health and related conditions of the students of two colleges in Masulipatam.** *J. Indian Med. Assoc.*, 1955, **25,** 446–450. [Hindu Coll., Masulipatam.]

The records of routine examinations of 9038 students made by the author since 1949 are summarised in respect of caste, parent's occupation, economic status, feeding habits, age, weight, height, chest circumference at inspiration and expiration, and incidence of disease.

From estimates of food consumption energy intake was calculated to be about 2400 Cal., which falls short of the requirement, taken as 2600 Cal. The number of subjects with signs of vitamin A deficiency was 140. Defective sight and pyorrhoea were the commonest clinical abnormalities.

The relation

$$X = \frac{A \times B}{18{\cdot}42}$$

was found between weight in lb. (X), height in inches (A) and mean chest circumference in inches (B).—D. Harvey.

KRAINICK, H. G., DEBATIN, F. and ZIERL, W. Inapparente Infektion und Stoffwechsel. [**Non-apparent infection and metabolism.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1350–1356. [Kinderklin., Univ. Freiburg i. Br.]

The first observation was made in a holiday camp among 37 diabetic children aged from 8 to 15 years. A girl who developed scarlet fever was sent to hospital; the others were treated with penicillin by mouth for 6 days, and none developed manifest scarlet fever. But 22 of them developed diabetic crises, the first to do so having severe acidotic coma before penicillin treatment was begun. The peak of the common rise in blood sugar was reached on the twelfth day after the infection was first detected. It was concluded that the metabolic disturbance was due to sub-clinical infection.

The second observation concerned a premature infant which at 3 weeks of age had, along with others in the ward, infection of the upper respiratory tract. These others had all the usual signs of such infection, but in this one there was only an increase of temperature to 37·6° C., which was accompanied by a fall in fat retention from 95 or 97 to 67 per cent. There was no dyspepsia.

DIETZE, A. Zur Frage der langdauernden vegetativen Regulationsstörungen nach alimentärer Dystrophie. [**Long-lasting injury to sympathetic regulation after nutritional dystrophy.**]

Münch. med. Wochenschr., 1955, **97**, 1733–1735. [Ärztl. Dienst, Versorgungsverwaltung, Schleswig-Holstein.]

Such minor effects of malnutrition as sweating, palpitations, cyanosis of the extremities, itching of the fingers, appearance of dermography and headache seemed often to persist long after the more important signs had disappeared. Living conditions after the return from imprisonment might have tended to prolong the symptoms.

An investigation was therefore made of 200 men showing such effects, who had been taken prisoner in 1944–45 and been returned to Schleswig-Holstein in 1948–49, and who had been back for at least 5 years. They had been under the care of their doctors and all showed disturbances of the sympathetic nervous system. They included a large proportion of men whose home was not in Schleswig-Holstein, who had been out of work for a long time, who had come down in the world, who had no proper dwelling and whose family life was broken. It was considered that such circumstances had tended to prolong the nervous disturbances or even to promote them.—E. M. Hume.

MEYERINGH, H., DIETZE, A. and HAESELER, W. Über den Gesundheitszustand der Spätheimkehrer der Jahre 1953/54. [**Health of late repatriates in the years 1953 and 1954.**] *Deutsch. med. Wochenschr.*, 1955, **80**, 1606–1612. [Arztl. Dienst, Versorgungsverwaltung, Schleswig-Holstein.]

The results of a study of 359 out of 486 late repatriates to Schleswig-Holstein in the winter of 1953–54 are discussed in conjunction with earlier work by the first author (Absts. 5689, Vol. 20; 2797, Vol. 22; 3613, Vol. 24) and others. Like earlier batches, these subjects had endured prolonged heavy work and underfeeding; and, as survivors, they may be a selected sample.

Only 25 (7 per cent.) had, or had had, lipophilic dystrophy, a much smaller proportion than before. Disorders of the circulation were still common, but mostly functional, though some had electrocardiographic changes which may have been due to dystrophy. Arteriosclerotic changes were no greater than in the ordinary population. There was evidence of a temporary rise in blood pressure when the feeding improved after the Russian currency reforms of 1948–49. Liver damage was established or suspected in 29 (9 per cent.) of 320 tested and was ascribed to dystrophy in 15 of these. Only 76 (21 per cent.) had had severe diarrhoea, and this relative freedom from digestive disorder may be the reason why these late repatriates were on the average in better physical condition than those who returned in 1948–49.

PASCHLAU, G. Zur Beurteilung der Salzsäuremangelzustände des Magens nach Hungerdystrophie. [**Assessment of the hydrochloric acid deficiency states of the stomach after hunger dystrophy.**] *Münch. med. Wochenschr.*, 1955, **97**, 1201–1205. [Ehem. Evangel. Krankenhaus, Göttingen-Rohns.]

In 171 patients with hunger dystrophy, gastric analysis during the first year after their return from Russia showed that 70 per cent. had anacidity and the remainder sub-acidity; none had normal acidity. Subsequent studies showed a slow recovery of normal secretion in just under half the patients. When complications were present the recovery might be delayed for up to 6 to 7 years, but in their absence recovery, when it occurred, was generally within the first 4 years. Success or failure in the restoration of acid secretion was not related to the occurrence or otherwise of dysentery or other gut infection during imprisonment. X-ray examination showed no difference in the extent of mucous membrane lesions between the groups. It was therefore concluded that delay in recovery was the result of the hunger dystrophy itself, and that the capacity to recover and the time required for it were related to the severity of the protein deficiency experienced. It is suggested that the delay in return of function may have been partly due to poor circumstances in which rest and good food were lacking.—L. Wills.

JELLIFFE, D. B. **Hypochromotrichia and malnutrition in Jamaican infants.** *J. Trop. Pediat.*, 1955, **1**, 25–33. [Univ. Coll. W. Indies, Jamaica.]

Hypochromotrichia is defined as a decrease in the colour of the hair in comparison with the colour usual for the ethnic group under consideration. By that definition in a recent study (Abst. 1152, Vol. 25) 15 of 18 patients with kwashiorkor showed depigmentation; some with histories of relapse had striped hair as described in FAO *Nutritional Studies* No. 13 (see p. 306, Vol. 25). The changes responded to high-protein diet. Among 252 poorly nourished individuals in a small village (see Abst. 3562, Vol. 24) the percentage with some degree of depigmentation was 75 in the age group from 1 year to 3 years, 62 from 3 to 9 years and only 6 from 9 to 17 years. The findings suggested that depigmentation of the hair, like frank kwashiorkor, which was not seen in the village, is related to the crisis which occurs at weaning. A further survey confirmed the findings and related the incidence of the hair changes to the socio-economic conditions. Paper chromatography of treated samples of normal and greatly depigmented hair yielded similar results for amino-acids. It is suggested that a hypochromotrichia index would be useful for assessing the state of protein deficiency among infants in malnourished African communities.—L. Wills.

LACROIX, A. C. Le myo-oedème socio-physiologique. Son intérêt dans la connaissance des états collectifs de malnutrition. [**Sociophysiological myo-oedema. Its interest in connection with states of collective malnutrition.**] *Bull. Soc. Pathol. exot.*, 1955, **48**, 185–191.

Oedema of the muscles, known to occur in conditions of starvation or severe undernutrition, was demonstrated by pinching the biceps and noting the appearance of a pad of swollen tissue. In 4700 Algerian Mohammedan recruits whose home diet was low in protein and fats, the percentage incidence was 93 in those from rural homes and 74 in the city dwellers. After the recruits had been for 6 months on army rations rich in animal protein, the percentage affected fell to 56·6.

MUKHERJEE, K. L. and JELLIFFE, D. B. **Clinical observations on kwashiorkor in Calcutta.** *J. Trop. Pediat.*, 1955, **1**, 61–66. [Calcutta Sch. Trop. Med.]

Fifteen classical cases of kwashiorkor in Calcutta are described. The picture differed from that commonly seen in African infants in that the hair changes were slight. There was a definite seasonal incidence of kwashiorkor and also of diarrhoea, of which almost every patient had a history. The possible effect on quantity and quality of the milk of the almost continuous lactation after repeated pregnancies is discussed.

DE SILVA, C. C. **Suprarenal haemorrhages in kwashiorkor: a preliminary report.** *J. Trop. Pediat.*, 1955, **1**, 112–116. [Dept. Paediat., Univ. Ceylon.]

In 3 of 15 fatal cases of kwashiorkor, haemorrhage into the adrenal glands was found at post mortem. All 3 cases were severe with a very short history. The possibility is discussed that an added stress such as infection or heavy infestation with parasites might precipitate a fulminating attack of kwashiorhor in a malnourished, susceptible child, and that it is patients with the acute disease that are liable to adrenal haemorrhage. See also next Abst.

L. Wills.

2303

DE SILVA, C. C. **Kwashiorkor (protein malnutrition).** *Ceylon Med. J.*, 1955, **3**, 55–79. [Dept. Paediat., Univ. Ceylon.]

The incidence of kwashiorkor as measured by the number of patients admitted to hospital has increased from 1·4 per cent. of 2168 in 1950 to 2·9 per cent. of 3113 admissions in 1954. Of 127 children treated in 1953 and 1954, 78 per cent. were between 1 and 4 years of age; only 38 per cent. were between 1 and 2 years, the age group into which about 75 per cent. of patients in Africa fall. Detailed studies were made of 30 patients, and much of the paper deals with the pathology and symptoms of the disease as seen in them. From information, roughly quantitative in nature, which was supplied by mothers there was no evidence that the children with kwashiorkor derived more of their energy from carbohydrate or less from protein than did those showing undernutrition. The finding at 15 post-mortem examinations that in 4 severe cases there was haemorrhage of the adrenal glands is thought to be evidence of Selye's general adaptation syndrome.

The prevention of the disease is a socio-economic rather than a public health problem. The solution proposed, namely, making available and encouraging the consumption of soya beans and fishery products such as dried sprats, is one which will require co-operation of several state departments.—D. Harvey.

2304

RAMANATHAN, M. K. **Biochemical changes in the serum in nutritional oedema syndrome (kwashiorkor).** *Indian J. Med. Res.*, 1955, **43**, 517–520. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Total protein, albumin, γ-globulin, urea, N.P.N., and cholesterol and its esters were estimated in the blood of a number of children showing the syndrome of nutritional oedema (kwashiorkor) before treatment with a high-protein diet began, again when the signs disappeared and finally on discharge from hospital. Control estimations were made on 12 healthy children.

Average values per 100 ml. serum at admission were: total protein 5·0 g., albumin 2·34 g., globulin 2·65 g., γ-globulin 1·33 g., urea 17·95 mg., N.P.N. 17·85 mg., total cholesterol 104·95 mg. and cholesterol esters 42·10 mg. Only the γ-globulin value was normal. All other values rose during treatment and at discharge were nearly normal. Reasons for the high γ-globulin value are discussed.

J. S. Thomson.

CHEUNG, M. W., FOWLER, D. I., NORTON, P. M., SNYDERMAN, S. E. and HOLT, L. E. (Jr.) (with HASSELMEYER, E.) **Observations on amino acid metabolism in kwashiorkor. (A preliminary report.)** *J. Trop. Pediat.*, 1955, **1**, 141–147. [Child Med. Serv., Bellevue Hosp., New York.]

In 3 patients with kwashiorkor, examination of the urine by chromatography on paper and with a Dowex 50 column showed in addition to the peaks of identified amino-acids 13 others due to unidentified substances reacting with ninhydrin. The total excretion of free amino-acids was expressed as the ratio $\frac{\alpha\text{-amino-N}}{\text{creatinine}}$ in g. daily, since the commonly used amino-acid index, $\frac{\alpha\text{-amino-N}}{\text{total N}}$ in g. daily $\times$ 100, gives very high values because of the very low excretion of total N in patients with kwashiorkor. Before treatment, in terms of creatinine, excretion of free amino-acids was not higher than normal, but during treatment it rose at first and, as the cure progressed, fell again to the values before treatment. Had the results been expressed in the second form the initial value would have been raised and the later values reduced. In 6 specimens from the 3 patients, chromatography showed a high ratio of *iso*leucine to leucine which was due to increased *iso*leucine excretion, and, with the exception of the initial specimen in the one case that was followed during treatment, a high ratio of phenylalanine to tyrosine due to increased excretion of phenylalanine. In the initial specimens the excretion of threonine was low in 2 but normal in the third.—L. Wills.

2306

CLOSE, J. Contribution à l'étude du rôle des acides aminés dans l'étiologie du kwashiorkor. **[The part played by amino-acids in the etiology of kwashiorkor.]** *Ann. Soc. belg. Méd. trop.*, 1955, **35**, 411–424. [Inst. Recherche Sci. Afrique Centrale, Centre Recherche Sci., Kivu, Lwiro, Belgian Congo.] Flemish summary.

Samples of breast milk were obtained from 2 African mothers, one with a 4-month-old infant, completely breast fed, and the other with a child of 12 months, fed partly on the breast and partly on a mixed diet; both babies had severe, typical kwashiorkor. The contents of ammonia, total N and total individual amino-acids were estimated and the 24-hr. volume of milk was recorded.

The results were compared with those for the pooled milk of 9 African women with normal babies, and with standard European and American values (Soupart *et al.*, Abst. 2851, Vol. 24 and Beach *et al.*, Abst. 885, Vol. 11). They showed that the total N in the 3 African samples was considerably higher than the mean values for Europeans and Americans. Expressed as a percentage of the total N, the sum of the N from the different amino-acids and from ammonia ranged from 85·3 to 87·6, compared with a mean value of 85·5 for the milk of European mothers. The amino-acids in the African samples were present in about the same proportions as in the European samples, except that the percentage of methionine was considerably lower, and that of arginine definitely higher, than the European standards, though the proportions agreed with American values (Macy, Abst. 4569, Vol. 19). In the sample from the mother of the 4-month-old infant the values for valine, lysine and proline were low compared with the values from the pooled sample; the values for lysine and proline were low also in the milk from the mother of the 12-month-old infant, and so was the value for cystine. In the 4-month-old infant the total milk available daily was found to be 405 ml. by expression, and 354 ml. by weighing before and after the feed; on such an intake the infant received only 4·256 g. amino-acid N though the intake calculated as desirable was 12·520 g. In European infants of the same age the average daily intake of milk is 800 ml. and of amino-acid N 8·064 g. The amino-acid N intake of the African infant was therefore only 35 per cent. of the standard put forward by Albanese (Abst. 820, Vol. 22), and 53 per cent. of the average European infant's intake; the deficiency of leucine and methionine was particularly marked. The results are discussed, and to meet criticism it is pointed out that Holemans has found the mean daily milk secretion in Central African women to be very low (*Inst. Roy. Colon. Belge, Mem.*, 1954, **25**, No. 3).—L. Wills.

2307

NETRASIRI, A. and NETRASIRI, C. **Kwashiorkor in Bangkok. [An analytical study of 54 cases.]**

J. Trop. Pediat., 1955, **1**, 148–155. [Dept. Paediat., Fac. Med., Univ. Med. Sci., Bangkok.]

Kwashiorkor, typical of that in other endemic centres, was seen in 54 patients of whom most were Thai children and not Chinese, probably on account of the better diet eaten by the Chinese. All belonged to the lower income groups and a history of infection and ascaris infestation was common. The clinical, biochemical and haematological findings were true to type except that skin changes were severe and eye changes caused by vitamin A deficiency were common. Riboflavin and vitamin B_1 deficiencies were also frequent. Treatment was along the usual lines except that to save sight vitamin A had to be used in large doses. The crude death rate was 24·1 per cent., but many of the patients were admitted in a moribund state.—L. Wills.

2308

THOMPSON, M. D. **Comparison of milk and soya beans in the treatment of kwashiorkor in Uganda.** *Brit. Med. J.*, 1955, ii, 1366–1369. [Mulago Hosp., Kampala.]

The patients were in 2 groups. Thirty-five were given cow's milk protein, and 42 a preparation of soya beans (see Abst. 2193, Vol. 23) with for some a vitamin preparation and for others methionine. The results were measured by the numbers in whom anorexia was overcome, oedema lost, weight gained and levels of total protein in serum and of enzymes in pancreatic fluid raised. They showed that milk was better than soya beans, but failure with the beans was in many cases caused by the difficulty experienced in preparing a product sufficiently concentrated to maintain the necessary intake of protein. Neither the vitamin B_{12} in the vitamin preparation nor the methionine improved the response to soya beans.

In a discussion of the findings the view is held that the people's greatest need is for education, namely, instruction of the adult population in the value and best use of the sources of protein available.—D. Harvey.

TROWELL, H. C., DAVIES, J. N. P. and DEAN, R. F. A. **Kwashiorkor and malnutrition.** *Acta paediat.*, 1955, **44**, 487–490. [Mulago Hosp., Makerere Coll. Med. Sch., Kampala, Uganda.] French, German and Spanish summaries.

In this reply to the discussion by Gómez *et al.* (Abst. 993, Vol. 26) the Uganda workers record their view that the term malnutrition is not sufficiently specific and maintain their preference for kwashiorkor as a name for the disease.—D. Harvey.

2310

DAVIES, J. N. P. **Children's diseases at Mulago Hospital 1950-51. An analysis of the causes of admission.** *East African Med. J.*, 1955, **32**, 283–290. [Dept. Pathol., Makerere Coll. Med. Sch., Kampala, Uganda.]

Malaria, respiratory disease and nutritional disorders, in that order, were the 3 commonest causes of admission. Diarrhoea and vomiting were usually the initial signs of an attack of malaria. In infants under 1 year of age marasmus was the commonest nutritional disorder, in those over 1 year kwashiorkor. The peak incidence of admissions for kwashiorkor was about 18 months or about 6 months after the peak incidence of malarial admissions, and the incidence of kwashiorkor fell more rapidly than that of malaria; few admissions for kwashiorkor occurred after the age of 3 years, but the incidence of admissions for malaria was high until about the 6th or 7th year. The difference in age incidence and other findings suggest that malaria and kwashiorkor are unrelated.

ASK-UPMARK, E. and MEURLING, S. **On the presence of a deficiency factor in the pathogenesis of amyoptrohic lateral sclerosis.** *Acta med. scand.*, 1955, **152**, 217–222. [Dept. Med., Royal Acad. Hosp., Upsala.]

Examinations were made of 111 persons who had undergone gastric resection. Diagnosis of amyotrophic lateral sclerosis was definite in 1 and problematic in 2 others. Of 20 patients in whom the diagnosis had been established in the decade 1945 to 1954, 5 had had gastric resection, 1 required it and 2 had diabetes with emaciation. Malnutrition in some form is suggested as a concomitant condition. (See Abst. 3602, Vol. 15.)

Vitamin A

2312

BASS, M. H. and CAPLAN, J. **Vitamin A deficiency in infancy.** *J. Pediat.*, 1955, **47**, 690–695. [Paediat. Serv., St. Joseph Hosp., Far Rockaway, N.Y.]

A normal infant, aged one month, developed allergy to cows' milk, as evidenced by the development of eczema. A soya bean preparation, Mull-Soy, was therefore given instead of milk, and was later supplemented with bananas, rice and peaches. By an oversight no vitamin A was provided. At the age of about 8 months the child was anaemic and mentally and physically backward. The corneas were blurred and had small ulcerations; and there was blood in the urine. During observation in hospital, hydrocephalus developed with

bulging of the anterior fontanelle. The temperature rose to 104° F. The absence of vitamin A from the diet was then realised, and rectified by daily intramuscular doses of 100,000 I.U. The temperature fell rapidly to normal, and in 2 days the fontanelle was flat. Within 10 days the child had completely recovered from all the abnormalities, and was discharged from hospital. In another infant, hydrocephalus developed as an effect of vitamin A deficiency caused by congenital absence of the bile duct. The hydrocephalus was corrected by injection of vitamin A, but the child died. The speed with which hydrocephalus can appear or disappear suggests that it cannot be caused by compression resulting from the abnormal growth of bone.—T. Moore.

GAMP, A. and GROS, H. Störungen des Vitamin-A-Stoffwechsels bei chronischer Polyarthritis. [**Disturbances of vitamin A metabolism in chronic polyarthritis.**] *Ztschr. ges. inn. Med.*, 1955, **10,** 597–600. [Klin. Rheumakranke, Bad Kreuznach.]

Vitamin A was estimated in the blood serum of 11 patients with chronic polyarthritis, 3 with chronic polyarthritis and Sjögren's syndrome, 8 normal persons and 6 patients with liver cirrhosis before and after administration of large amounts of vitamin A. The mean values before administration, in I.U. per 100 ml., were for the healthy persons 224 with range 184 to 270, for those with chronic polyarthritis 173 with range 104 to 225, and for those with liver cirrhosis 95 with range 0 to 178. Individual values for the 3 patients with Sjögren's syndrome were 176, 176 and 250. A single dose of 150,000 I.U. vitamin A was given twice, once before administration of the same dose daily for 6 days and once 2 days after it. The responses of the arthritic patients did not differ greatly from those of the healthy subjects unless the liver or spleen was affected, when the response was less : in the patients with liver cirrhosis the response was much less.—E. M. Hume.

HISSARD, R., JACQUET, J. and VILLETTE, O. Gale norvégienne et vitamine A. [**Norwegian itch and vitamin A.**] *C.R. Acad. Sci.*, 1955, **241,** 1003–1005.

In a woman aged 46 with Norwegian itch the infestation with sarcoptes was associated with hyperkeratosis, manifested by the formation of crusts on the skin. There was a history of chronic alcoholism, and Laennec's cirrhosis had developed with ascites. Secondary deficiency of vitamin A was suspected, and was confirmed by analysis of the blood plasma. Massive oral and parenteral doses of vitamin A raised the blood value, arrested the hyperkeratosis and reduced the vitality of the sarcoptes. The benefit lasted only for as long as the treatment was continued, and the hyperkeratosis could be made to regress or increase repeatedly according to whether the vitamin was given or not. Eventually a permanent cure was effected by combining vitamin A administration with attacks on the sarcoptes by means of benzyl benzoate.—T. Moore.

Vitamin D

2316

AMERICAN MEDICAL ASSOCIATION, COUNCIL ON FOODS AND NUTRITION. **Importance of vitamin D milk.** *J. Amer. Med. Assoc.*, 1955, **159,** 1018–1019.

The Council expresses the opinion that the general use of vitamin D milk in the United States in recent years has played an important part in reducing the incidence of rickets to the existing extremely low level. Council will continue its present policy of encouraging the use of milk fortified with 400 U.S.P. units of vitamin D per quart.

BERRY, W. T. C., BOYES, K. M. B., PARR, W. C. and SMITH, K. F. **Children who take no cod liver oil.** *Monthly Bull. Minist. Health and Pub. Health Lab. Serv.*, 1955, **14,** 162–165. [Minist. Health, Savile Row, London, W.1.]

A study was made in late winter in Salford, where there is little sun and much rain, of 37 children between the ages of 1 and 2 years who had had no cod liver oil or only a little and of 50 children who were known to have had at least 1 teaspoonful on 5 days a week for 6 months. Of the first group 27 had been reared on dried or evaporated milk and their average daily intake of vitamin D was estimated at 700 I.U. The others had been reared mainly on cow's milk after a short period of breast feeding and their daily intake of vitamin D was estimated to range from nil to 300 I.U. During the second year of life the average daily intake of vitamin D by the first group was only about 25 I.U. ; that of the group given cod liver oil about 450 I.U.

Only 12 of the first group were judged clinically to be in good condition, compared with 34 of the group given cod liver oil, and only 13 were above expected weight for age, compared with 28, but a number of them were from problem families, so

that the inferiority may not have been due to lack of cod liver oil. Six were suspected of having early rickets, but no rickets, healed or active, was detected in any of the children by X-ray photography of the wrist. The value for serum alkaline phosphatase, the state of tooth eruption, and the Hb value did not differ significantly between the groups.

It is pointed out that some of the infants on dried milk would have been taking as much as 2300 I.U. vitamin D daily at 6 months if they had had cod liver oil as well, and it is suggested that dangerously high values for Ca in the blood might have resulted.—W. M. Deans.

2318

FANCONI, G. Das Vitamin D als Heilmittel und als Gift. **[Vitamin D as a medicament and as a poison.]** *Schweiz. med. Wochenschr.*, 1955, **85,** 1253–1261. [Kinderklin., Univ. Zürich.]

In a lecture the great variation in the individual requirement of vitamin D is stressed. Examples are given of children with rickets when receiving what would appear to be a sufficient supply, and of children showing detrimental effects from relatively small doses. The case of a girl of 14 is cited; she showed high blood Ca and stunted growth after receiving the equivalent in halibut liver oil of 2 tablespoonfuls of cod liver oil daily for a year. Other topics considered are idiopathic hypercalcaemia, vitamin-D-resistant rickets and phosphate diabetes.—E. M. Hume.

HALLMAN, N., HJELT, L. and TÄHKÄ, H. **Chronic hypercalcemia and vitamin D in early childhood. 1. Clinical observations.** *Ann. Paediat. Fenn.*, 1954–55, **1,** 338–354. [Child. Clin., Univ. Helsinki.]

Eleven children aged from 6 to 29 months were admitted to hospital for failure to thrive, with slow weight increase, lack of appetite, vomiting and constipation. All had a high plasma Ca value; some had previously had interstitial pneumonia which is accompanied by a high plasma Ca value, and all had had large single intramuscular doses of vitamin D. All except 3 were premature. All were mentally and physically backward. Blood and urine were investigated. All the children were anaemic. Plasma Ca values ranged from 13·5 to 15·0 mg. per 100 ml. Values for plasma inorganic P were normal, for alkaline phosphatase were low and for plasma and erythrocyte Mg high in some instances; values for urea N and N.P.N. were high. There was proteinuria. Treatment was with a diet low in Ca and without vitamin D. Two babies died of intercurrent infection but the rest recovered. It is customary in Finland to give premature infants a single intramuscular injection of 250,000 I.U. vitamin D_2 at from 3 to 4 weeks of age, followed by another of 500,000 I.U. a month later, and to continue prophylaxis with oral doses of from 3000 to 5000 I.U. daily. It is recognised that such amounts are large.—E. M. Hume.

CARTER, R. E. B., DENT, C. E., FOWLER, D. I. and HARPER, C. M. **Calcium metabolism in idiopathic hypercalcaemia of infancy with failure to thrive.** *Arch. Dis. Childhood*, 1955, **30,** 399–404. [University Coll. Hosp. Med. Sch., London.]

Detailed clinical, metabolic and biochemical studies were made of idiopathic hypercalcaemia in a boy of 9 months old. There was no evidence that excessive amounts of vitamin D had been given. The serum Ca value was 13·8 mg. per 100 ml. The administration of 10,000 "units" of vitamin D daily for 12 days resulted in an immediate rise of the Ca value in the plasma and deterioration of the clinical condition. Later the boy was maintained on a constant Ca-free diet without vitamin D, to which was added for different periods 610 mg. Ca daily; the plasma value rose and fell with the Ca intake and the plasma urea tended to fluctuate with the Ca value; on a mixed diet containing about 200 mg. Ca, plasma Ca rose at first but fell again later. The clinical condition reflected closely and rapidly the plasma value for Ca. After about 4 months under observation the patient gradually became more tolerant of Ca and after 12 months was able to take a normal diet. Growth and development were then normal. It is concluded that the condition is caused by abnormal sensitivity to vitamin D.—L. Wills.

2321

BRYANT, H. **Unprescribed medicaments, medical advice and vitamins in infancy.** *Med. Officer*, 1955, **94,** 209–212. [Bolton, Lancs.]

Information was obtained about the medicaments given without medical advice in the first year of life to 503 of the 586 infants born in Bolton during 3 consecutive months; 63·4 per cent. of them belonged to the Registrar-General's social and economic group 3. Only 8 infants received no unprescribed medicine. There was no significant difference between the social classes in the amounts of unprescribed vitamin preparations given, but more than half of the 58 infants who received no vitamin addition belonged to social class 5. To 97 infants no vitamin was given apart from the cod liver oil and orange juice received through the Welfare Food service, and 8·6 per cent. of all the infants received no supplement of vitamins A and D at all.—L. Wills.

2322

DENT, C. E., HARPER, C. M., MORGANS, M. E., PHILPOT, G. R. and TROTTER, W. R. **Insensitivity to vitamin D developing during the treatment of postoperative tetany. Its specificity as regards the form of vitamin D taken.** *Lancet*, 1955, **269**, 687–690. [Med. Unit, University Coll. Hosp., London.]

In 4 patients after accidental removal of the parathyroid glands during operations on the thyroid gland, the consequent tetany at first responded to treatment with vitamin D_2, and large amounts caused hypercalcaemia and signs of excess. Later the vitamin ceased to be effective even in doses as large as 8 mg. daily. A change to A.T. 10 or, with one patient, to vitamin D_3 immediately controlled the tetany and the patients were satisfactorily maintained with daily doses of 1 mg. or less of A.T. 10 or of 2 mg. vitamin D_3. Tests for plasma Ca and Ca balance during the periods of resistance confirmed the failure of vitamin D_2 to influence the Ca metabolism at that time. Vitamin D_3 or A.T. 10, however, immediately raised the amount of Ca in the plasma and urine, and decreased the plasma P and the amount of Ca in the faeces.

It is thought probable that the same state of resistance might arise with any form of vitamin D if given in large doses for a considerable time, and in treating post-operative tetany change of the preparation from time to time is recommended.

GREGERSEN, E. **Primary vitamin-resistant rickets.** *Acta paediat.*, 1955, **44**, 491–500. [Paediat. Dept., Copenhagen County Hosp., Gentofte.] French, German and Spanish summaries.

The case described is that of a girl first seen at the age of 22 months but whose development had not been normal since the age of 12 months. She had received up to 3500 "units" of vitamin D daily from about 7 months old, but had severe rickets. A cure was effected with 300,000 "units" of vitamin D daily, and the patient was maintained with 50,000 "units" daily for a year, but was then lost sight of till she was re-admitted at the age of 8 with severe deformities and a fracture. For cure 600,000 "units" of vitamin D_2 daily were needed, but signs of overdosage were liable to appear. Maintenance was with 150,000 "units" daily. The need for continued treatment is stressed. The case presented no special feature.

JUNG, W. Phosphataseuntersuchungen im mütterlichen und kindlichen Blut. Ein Beitrag zur Frage der angeborenen Rachitis. [**Estimations of phosphatase in the blood of mother and child. Communication on congenital rickets.**] *Monatsschr. Kinderheilk.*, 1955, **103**, 347–350. [Kinderklin., Univ. Mainz.]

Serum alkaline phosphatase was estimated during the winter and spring in the maternal and cord blood of 220 women. None of the mothers had received vitamin D in pregnancy, and birth was at term. For 40 non-pregnant women a mean value of 8·2 with range from 5 to 13 "units" [presumably per 100 ml.] had been obtained. The mean value for the maternal blood was 20·2 "units" with range from 12 to 36, and for the cord blood 16·35 with range from 10 to 28. There was no relation between the two values for individuals. Estimation was made on the venous blood of 50 of the babies within the first 6 days of life; the results were closely similar to those for the cord blood. In half the infants X-ray photographs were taken of both wrists, but there was no sign of rickets. Previous experience had shown that administration of 15 mg. vitamin D_3 from 6 to 8 weeks before term did not prevent the increase of phosphatase. It is concluded that the high values are the expression of a physiological state, and are not a sign of congenital rickets.

FELDER, J. and SCHREIER, K. Hypophosphatasie. [**Low phosphatase.**] *Monatsschr. Kinderheilk.*, 1955, **103**, 437–443. [Kinderklin., Univ. Heidelberg.]

An account is given of a child of 19 months, undersized, malnourished and with kyphosis, a rachitic rosary and enlarged epiphyses. The urine contained quantities of cylinders of amorphous salts. Alkaline phosphatase was almost completely absent from the blood and urine and from material obtained by sternal puncture. Ca and P in the blood serum were within the higher range of normal; in the urine they were very high. Treatment with 50,000 I.U. vitamin D daily had only a detrimental effect. Although the condition was not apparent at birth, it is considered to be a rare inborn error of metabolism of which only 3 other cases have been described. The prognosis was uncertain.—E. M. Hume.

2326

KAWAZOE, K. **Roentgenological studies on the curvature of fibula shaft in rickets.** *Tokushima J. Exp. Med.*, 1955, **2**, 45–52. [Dept. Paediat., Sch. Med., Univ. Tokuskima.]

Measurements were made from X-ray photographs of indices of curvature of the fibula at points one-quarter, half and three-quarters of the way up. The subjects were 89 healthy children and 478 who had rickets. In the normal children convexity was internal and, at each point of measurement, increased with age.

Of the rachitic children under 1 year of age, 231 were well nourished and 119 malnourished. When they were grouped according to 3 degrees of increasing severity of rickets, internal convexity in each group was greater in the malnourished than in the well nourished patients. Among those over 1 year of age and able to walk, convexity was external at the lower part of the fibula. In patients with bow-legs or knock-knees the curvature of the fibula generally followed that of the tibia.—D. Harvey.

Vitamin E

2327

Di Nardo, A., Gatti, E. and Pace, G. Vitamina E e diabete mellito. (Comportamento di alcuni aspetti del ricambio lipidico e glucidico.) **[Vitamin E and diabetes mellitus. Some aspects of lipid and carbohydrate metabolism.]** *Acta vitaminol.*, 1955, **9,** 172–180. [Div. Med. "Brera", Nuovo Osp. Magg.] French, English, German and Spanish summaries.

Total lipids, total and free cholesterol and phospholipins in the blood, and fasting blood sugar were estimated in 8 diabetics before and during treatment for from 20 days to 9 months with 400 mg. *d*-α-tocopheryl acetate daily; 2 of the subjects received insulin as well. Five other diabetics were treated with vitamin E in the same dosage for 10 days, and the response of the blood sugar to 0·75 g. glucose per kg. bodyweight and sensitivity to insulin were tested beforehand and at intervals for 4 hr. afterwards. In 4 diabetics blood sugar was measured at intervals up to 1½ hr. after administration in successive tests of glucose alone, glucose with insulin, and glucose with insulin from 5 to 6 hr. after a single oral dose of 10 g. vitamin E had been given.

In none of the 3 experiments was any consistent influence of vitamin E shown.—E. M. Hume.

Vitamin B Complex

2328

Pett, L. B. **Vitamin requirements of human beings.** *Vitamins and Hormones*, 1955, **13,** 213–237. [Div. Nutrit., Dept. Nat. Health Welfare, Ottawa.]

2329

Grüneis, P. Ueber die Behandlung akuter Leberparenchymerkrankungen mit hohen Dosen von Vitamin B-Komplex und Desoxycorticosteronacetat. **[Treatment of acute parenchymatous liver disease with large doses of the vitamin B complex and deoxycorticosterone acetate.]** *Wien. klin. Wochenschr.*, 1955, **67,** 725–729. [1. Med. Abt., Städt. Allg. Poliklin., Vienna.]

During a period of 9 years the use of deoxycorticosterone acetate combined with large doses of vitamin B complex proved valuable as an initial treatment in many forms of acute hepatitis. Case histories are quoted to show the beneficial effects on the disease and on the general condition of the patients. A table is given showing the diverse types of jaundice in 37 patients treated during the last two years and the relatively short stay in hospital required after treatment with the hormone and B vitamins. Both components appeared to be necessary, but their precise effects are unexplained.—A. M. Copping.

2330

Colombo, C. and Verga, G. Indagini sulla fluorescenza linguale alla luce di Wood in psichiatria. Osservazioni su 411 soggetti. **[Lingual fluorescence under Wood's light in psychiatry. Observations on 411 subjects.]** *Acta vitaminol.*, 1955, **9,** 157–162. [Clin. Malatt. Nerv., Univ. Milan.] French, English, German and Spanish summaries.

In most persons the dorsal surface of the tongue shows an orange-red fluorescence in Wood's light. It is considered probable that the fluorescence is connected with the metabolism of porphyrin. In 214 healthy persons examined by Tomaszewski, fluorescence was absent in 39 (*Brit. Med. J.*, 1951, i, 117).

Lingual fluorescence was investigated in 411 patients in the Psychiatric Hospital in Milan. Intensity of fluorescence could not be measured, but it was described as partial when it was shown by less than two-thirds of the tongue. The incidence varied in different types of patient. Fluorescence was absent in about half the patients with alcoholism, depression or syphilis. The incidence was normal in epileptics and senile patients, fluorescence being absent in about 19 per cent. Schizophrenics had an intermediate value of 31 per cent. It is pointed out that owing to their condition many of the patients might be taking deficient diets, lacking particularly the B vitamins. Lingual fluorescence is regarded as a useful guide to nutritional status.—E. M. Hume.

2331

Masuda, K., Okamura, K., Aoyama, J. and Obara, M. **Clinical observations of so-called "Shibi-Gatchaki," an endemic malnutrition associated with one-sided rice diet.** *J. Vitaminol.*, 1955, **1,** 229–248. [Masuda Hosp., Goshogawara, Aomori-ken.]

The syndrome, which occurred in from 50 to 70 per cent. of the population, was studied in 100 patients of all ages. All the subjects showed signs and symptoms of deficiency of both riboflavin and nicotinic acid and other signs of

malnutrition. Lesions of the skin and mucous membranes were very frequent, anal and genital itching was present in 51, glossitis in 91 and angular stomatitis in 75. Laboratory tests on 33 showed abnormal liver function in about half, macrocytic anaemia in two-thirds and a positive Millon's test in 9 out of 10. The 24-hr. excretion of vitamin B_1, riboflavin and N^1-methylnicotinamide in the urine was low, as was the value for riboflavin in the blood. The syndrome was considered to be a multiple deficiency of B vitamins; it usually responded to treatment with the vitamin B complex. It was attributed to malnutrition from weaning, when the diet of the infant, like that of all the people in the district, is highly polished rice with only very small amounts of other foods.

KING, J. H. (Jr.) and PASSMORE, J. W. **Nutritional amblyopia. A study of American prisoners of war in Korea.** *Amer. J. Ophthalmol.*, 1955, **39,** No. 4, Part 2, *Suppl.*, 172–186. [Ophthalmol. Serv., Walter Reed Army Hosp.]

Twenty-two subjects with nutritional amblyopia were studied. Most of them were captured early in the Korean war when conditions for prisoners were especially bad. Loss of sight had been gradual; the average period before onset was 11 months. The diet reported was deficient in many ways but deficiency of vitamin B_1 was thought to be the one which was responsible. Of the other diseases from which prisoners suffered, beriberi was present in a larger proportion of those with amblyopia than of those without it. The state of the eye was studied in detail. The typical findings in the chronic stage of the disease were reduced vision, bilateral, pericentral or paracentral scotomata about 5 degrees in size, and temporal pallor of the head of the optic nerve. Electroretinograms suggested that the atrophy of the optic nerve, as evidenced by the pallor and atrophy of the disc, was ascending in type, and that there was involvement of the retina with the rods and cones affected.

Treatment was with a diet high in energy, protein and vitamins. Only two patients showed improvement, but visual aids provided help.

BEAL, V. A. **Nutritional intake of children. 3. Thiamine, riboflavin and niacin.** *J. Nutrition*, 1955, **57,** 183–192. [Child Res. Counc., Univ. Colorado Sch. Med., Denver.]

For part 2 see Abst. 2566, Vol. 25.

Intakes of vitamins by 63 children during the the first 5 years of life were assessed from 934 24-hr. diet histories obtained at intervals of a month up to 6 months of age and then at intervals of 3 months. The results are tabulated with maximum and minimum values and 25th, 50th and 75th percentiles to show the true distribution of the results. The vitamin B_1 intake rose steadily for the first 15 months, then remained unchanged till 3 years of age, when it again increased up to 5 years. The riboflavin intake increased for the first year, decreased in the second and third years and then rose again. The nicotinic acid intake generally increased throughout the age span studied. For vitamin B_1 and riboflavin the intakes were slightly above the recommended allowances of the National Research Council (1953) for the age groups, and for nicotinic acid they were slightly below, but there was no evidence that they were inadequate.—A. M. Copping.

BALAKRISHNAN, S. and RAJAGOPALAN, R. **Thiamine nutrition status of human subjects receiving supplements of curds.** *Indian J. Med. Res.*, 1955, **43,** 559–568. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

Three similar groups of children were given the same basic poor rice diet, one group without supplement, another group with 0·5 lb. curd daily providing extra energy (protein) as well as about 90 μg. vitamin B_1 and other B vitamins. In the third group each child received 90 μg. synthetic vitamin B_1 in 1 g. sugar daily. At the end of 2 months the children receiving curd showed an average weight gain of 1·35 lb. and an increase in faecal and urinary excretion of vitamin B_1, attributed to increased synthesis of vitamin B_1 in the gut. No such change was seen in the children in the other 2 groups.—L. Wills.

2335

HOLT, L. E. (Jr.) and SNYDERMAN, S. E. **The influence of dietary fat on thiamine loss from the body.** *J. Nutrition*, 1955, **56,** 495–500. [Dept. Paediat., Coll. Med., Univ. New York.]

The vitamin B_1 requirement of 2 infants aged 8 and 18 months was estimated as previously described (Abst. 1209, Vol. 19), and the diet was then changed to one in which 80 per cent. of calories was provided as carbohydrate instead of 50 per cent., and calories from fat were restricted to 10 per cent. With the change urinary excretion of vitamin B_1 decreased, and rose to its original value only after an increase of about 40 per cent. in the intake of vitamin B_1. An increase in demand for vitamin B_1 in metabolic processes with increase of carbohydrate is deduced.

LICHTENBELT, H. K. v. M. and FLORIJN, E. **Treatment of diabetic coma with thiamine pyrophosphate.** *Acta med. scand.*, 1955, **152**, 259–269. [Dept. Med., Univ. Hosp., Utrecht.]

To ascertain whether there is a deficiency of vitamin B_1 pyrophosphate in diabetic coma, blood pyruvic acid was estimated by a method eliminating acetoacetic acid which had been shown to be estimated with pyruvic acid. With this method, only an insignificant rise of blood pyruvic acid was found during diabetic acidosis, and it was probably due to restlessness. Vitamin B_1 pyrophosphate in the blood was estimated in normal subjects and in diabetics with and without acidosis. In none of them was the value ever below normal though it was frequently significantly higher in the diabetics, a result providing evidence that phosphorylation of vitamin B_1 is normal in diabetes. To confirm the result the formation of vitamin B_1 pyrophosphate after intravenous injection of 60 mg. vitamin B_1 was estimated in healthy subjects and in patients in diabetic coma, and found to be greater in the diabetics. There was no difference between healthy and diabetic subjects in the rate of disappearance of vitamin B_1 pyrophosphate from the blood after an intravenous injection of 100 mg. of it. Prolonged treatment of diabetic coma led to a significant fall in the blood pyrophosphate value, but the value could be restored by giving vitamin B_1 orally or parenterally. Treatment with vitamin B_1 pyrophosphate had no effect on the values for blood sugar, pyruvic acid, or acetoacetic acid or on the alkali reserve of patients with diabetic acidosis, and it did not cause any clinical improvement.

It is therefore concluded that there is no failure in phosphorylation of vitamin B_1 in diabetic coma and no indication for the use of the pyrophosphate. since the relative deficiency which develops during treatment can be successfully treated with vitamin B_1.—L. Wills.

BENSAUDE, A., JOUAN, F. and BERNARD, G. Contribution à l'étude du prolapsus rectal de l'enfant. [**On rectal prolapse in children.**] *Presse méd.*, 1955, **63**, 1533–1534. [Paris.]

A study of the social and economic background of 40 infants with rectal prolapse showed that 26 belonged to the poorest class, 33 came from extremely unhealthy homes and 26 were dirty. Digestive troubles were present in 28, associated in 24 with other pathological conditions, and 13 had histories of recent severe illness. Treatment with one or more courses of 12 intramuscular injections each of 50 mg. vitamin B_1 resulted in cure or great improvement in 32 of the patients; of the 8 failures only 4 required operation. Inquiry from 6 months to 2 years later showed no relapse.

GAIER, H. and JANTSCH, H. Beitrag zur therapeutischen Leistung und Wirkungsweise des Vitamin-B_1-haltigen Rosskastanienextrakts Venostasin bei peripheren arteriellen Durchblutungsstörungen. [**The therapeutic effect and mode of action of the vitamin-B_1-containing horse chestnut extract Venostasin in peripheral arterial circulatory disturbances.**] *Wien. klin. Wochenschr.*, 1955, **67**, 879–882. [1. Chirurg. Klin., Univ. Vienna.]

Of 85 patients with vascular disease treated by injection of Venostasin (Oesterr. Ichthyol G.m.b.H. Seefeld, Tirol), almost all showed good effects after the first few doses. Improvement in circulation, pulse rate, blood pressure, skin colour and general condition was noted. It was considered that the probable function of the extract, which contained vitamin B_1, was to raise capillary resistance and decrease permeability, and to produce a tonic effect on the blood vessels and changes in blood chemistry including alterations of cholesterol metabolism.—A. M. Copping.

HERSOV, L. A. **A case of childhood pellagra with psychosis.**

RODNIGHT, R. and MCILWAIN, H. **Indicanuria and the psychosis of a pellagrin.** *J. Mental Sci.*,

1955, **101,** 878–883; 884–889. [Dept. Biochem., Inst. Psychiat., Maudsley Hosp.]

Pellagra is described in a boy of 10 years whose diet had been mainly of tinned foods. In addition to the usual skin lesions the boy had slight neurological signs and severe confusional psychosis. On a full diet there was no improvement, but treatment with nicotinic acid, nicotinamide, and a high-protein and carbohydrate diet with extra milk, and Marmite resulted in prompt improvement, complete healing of the skin lesions in 14 days and a gradual return to normal mentality. The only abnormal pathological and biochemical finding was a high urinary output of indican. As the boy did not respond at all to a normal diet it was argued that his deficiency resulted from a high requirement and not from a low intake of the vitamin.

The urinary excretion of nicotinic acid metabolites was estimated in the same boy and in a healthy boy of the same age, while having a diet providing about 10 mg. nicotinamide daily, and the same diet with the addition of 100 mg. nicotinamide daily. There was no striking difference between the subjects in their excretion of nicotinic acid metabolites. Estimation of urinary indican output in normal children showed that it ranged from 10 to 150 mg. daily, the amount excreted increasing with age. A boy of the same age as the patient excreted less than 100 mg. daily, the patient from 230 to 360. Change in the intestinal flora or oral administration of 1·5 g. *l*-tryptophan with 1 g. *d*-tryptophan on 2 successive days had no significant effect on the urinary excretion of indican. It is suggested that indicanuria may cause loss of tryptophan and increase the requirement for nicotinamide.—L. Wills.

FRAZIER, E. I., PRATHER, M. E. and HOENE, E. **Nicotinic acid metabolism in humans. 1. The urinary excretion of nicotinic acid and its metabolic derivatives on four levels of dietary intake.** *J. Nutrition,* 1955, **56,** 501–516. [Dept. Home Econ., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Six healthy young women of similar physique and basal metabolic rate were given a diet containing 11·3 mg. nicotinic acid daily for 18 days, then 14·3 mg. daily for 10 days, then 7·2 mg. for 12 days and finally 16·3 mg. for 13 days. The first increase in intake of nicotinic acid gave increased excretion of nicotinic acid and its metabolites to a total equivalent to 86 per cent. of intake. The first decrease in intake was followed by a decrease in output, but the total output was 128 per cent. of the intake. When the intake was again increased the output increased, especially of N^1-methylnicotinamide and pyridone derivatives. In the last period the output was only 77 per cent. of the intake. There was considerable variation in the metabolic performances of the 6 subjects. The observations are discussed with reference to probable normal requirements for nicotinic acid and tryptophan.—A. M. Copping.

BARTLETT, M. N. **Red blood cell niacin and plasma riboflavin levels in a group of normal children.** *J. Nutrition,* 1955, **57,** 157–168. [Child Res. Counc., Univ. Colorado Med. Centre.]

Nicotinic acid in the red blood cells and riboflavin in the plasma were estimated by fluorimetric methods in blood from healthy children aged from 2 days to 16 years. In 86 children nicotinic acid was estimated in the red cells at intervals during 5 years, and a similar study of plasma riboflavin was made in 92 children. In addition nicotinic acid was estimated in 185 and riboflavin in 120 other normal children. The results, presented as scatter diagrams, showed no correlation between the intake of nicotinic acid or riboflavin and the blood values for those vitamins. The median value for the two vitamins remained almost constant from the third year of life with no change related to growth. The range of values at all ages was very wide and no significant difference was found between boys and girls.—A. M. Copping.

2345

DE, H. N., DATTA, P. and MANKAD, P. N. **Studies on riboflavin metabolism with typical Indian dietaries.** *Indian J. Med. Res.,* 1955, **43,** 501–509. [Dept. Biochem., Mahatma Gandhi Mem. Med. Coll., Indore.]

Metabolism studies were made on 13 subjects, 8 eating typical vegetarian diets, and 5 non-vegetarian diets with wheat or rice as staple cereal. The daily intake of riboflavin ranged from 0·83 to 1·35 mg. for vegetarians and from 0·94 to 1·14 mg. for non-vegetarians. The vegetarians excreted from 8·5 to 19·8 per cent. of their intake and the non-vegetarians from 18·2 to 26·8 per cent. When a test dose of 5 mg. riboflavin was given with the basal diet the maximum amount excreted was about 20 per cent. of the dose. If 10 mg. riboflavin daily was given for a week, up to 66 per cent. of the test dose of 5 mg. was excreted. In subsequent periods with daily doses of 2 mg. or 1 mg. followed by a test dose of 5 mg. the amount excreted remained of the same order as that obtained by saturation with 10 mg. daily. Hence it is considered that typical Indian diets based on cereals such as rice, wheat or jowar, with or without animal protein, supply the minimum necessary amount of riboflavin.—A. M. Copping.

2346

CHAPMAN, D. G. and CAMPBELL, J. A. **Reliability of the riboflavin excretion technique in determining availability of coated tablets.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 753–757. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa.]

In order to confirm the validity of a urinary excretion test for availability of riboflavin in sugar-coated tablets (*J. Amer. Pharm. Assoc., Sci. Ed.*, 1954, **43**, 297) the response of 8 men to graded doses of riboflavin was examined. For doses of 1, 3 or 5 mg. the excretion was the same whether the amount was given as a single dose or in 10 small doses. With doses of 1, 3, 5, 7·5 and 10 mg. the amounts excreted in the urine during the following 24 hr. were in proportion to the dose. The equation for the mean response line was

$$y = 0{\cdot}580\,x - 0{\cdot}610.$$

The lines did not pass through the origin and there was a difference in slope for the individual subjects. The results confirmed those previously reported.

BEIGLBÖCK, W. and KAHLE, R. Über die Beeinflussung des Hippursäuretestes durch Pantothensäure. [**Influence of pantothenic acid on the hippuric acid test.**] *Klin. Wochenschr.*, 1955, **33**, 1056–1057. [Inn. Abt., Städt. Krankenhaus, Buxtehude.]

Administration of pantothenate at the same time as, or 30 min. before, injection of sodium benzoate caused an increase in the amount of hippuric acid excreted. The same effect was seen in patients with normal liver function and with different forms of liver disease. The role of pantothenate in acetylation processes is discussed and its use in treating patients with disturbed liver function is suggested.—A. M. Copping.

2348

RAUSCH, E. Vorläufige Ergebnisse über die klinische Verträglichkeit von Paratebin mit Pantothenat. [**Preliminary results with pantothenic acid on the clinical tolerance for Paratebin.**] *Münch. med. Wochenschr.*, 1955, **97**, 1625–1626. [Orthopäd. Klin., Univ. Cologne.]

In trials with adult patients it was found that large doses of Paratebin (streptomycin) could be given without neurotoxic side reactions if pantothenate was administered at the same time. In 3 children with tuberculous meningitis very high doses of streptomycin were well tolerated when pantothenate was given.—A. M. Copping.

2349

VILTER, R. W. **Vitamin B_6 in medical practice.** *J. Amer. Med. Assoc.*, 1955, **159**, 1210–1213. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

In a review article dealing with the vitamin B_6 group of substances, the chemistry, distribution in nature, availability in different forms, human requirements and role in the cell are discussed briefly. Methods used to detect deficiency of vitamin B_6 are reviewed, and the amount of xanthurenic acid excreted in the urine after a test dose of *dl*-tryptophan is considered to be the most reliable. Reports are quoted of the production by means of a deficient diet of a deficiency state characterised by convulsions and anaemia, and reversed by treatment with vitamin B_6, in 2 hydrocephalic infants, and of the production, again with a deficient diet, of seborrhoeic dermatitis and mental changes in adults.—L. Wills.

2350

COURSIN, D. B. **Vitamin B_6 deficiency in infants. A follow-up study.** *Amer. J. Dis. Child.*, 1955, **90**, 344–348. [Res. Inst., St. Joseph's Hosp., Lancaster, Pa.]

Twenty infants, previously showing severe disturbance of the nervous system (Abst. 3647, Vol. 24) when being fed on a milk mixture supplying 60 μg. vitamin B_6 per litre, were kept under observation for up to 3 years. Each patient was treated initially with vitamin B_6 and then received a diet containing adequate amounts of the vitamin. Physical and mental development and electro-encephalograms were completely normal.—L. Wills.

2351

GLENDENING, M. B., COHEN, A. M. and PAGE, E. W. **Influence of pyridoxine on transaminase activity of human placenta, maternal and fetal blood.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 25–28. [Dept. Obstet. Gynaecol., Univ. California Sch. Med., San Francisco.]

Glutamic-aspartic transaminase activity was measured by a modification of the method of Tonhazy *et al.* (Title 3155, Vol. 20) in the blood of non-pregnant and pregnant women and in the cord blood and placenta at delivery. Activity resides chiefly in the blood cells. There was no significant difference between the values for non-pregnant and pregnant women; the latter were doubled when daily doses of 10 mg. pyridoxine were given. Cord blood showed high transaminase activity which was apparently not related to that of the maternal blood. Transaminase activity was high also in placental tissue and was not affected by giving pyridoxine to the mother for several weeks before delivery. It is suggested that foetal tissues contain optimum amounts of vitamin B_6 but that adult tissues do not, and that a supplement of the vitamin may be desirable during pregnancy.—A. M. Copping.

2352

MARQUEZ, L. R. and REYNOLDS, M. S. **Intake and elimination of vitamin B_6 and metabolites by women. 1. Non-pregnant women.**

TURNER, E. R. and REYNOLDS, M. S. **2. Pregnant women.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 1116–1118; 1119–1120. [Dept. Foods Nutrit., Sch. Home Econ., Univ. Wisconsin, Madison.]

1. In 6 healthy women aged from 33 to 35 years eating a diet of their own choice, the average daily intake of vitamin B_6 was 0·86 with range 0·52 to 1·2 mg. The daily faecal excretion ranged from 0·224 to 0·760 mg.; the daily urinary excretion from 0·064 to 0·126 mg. as the vitamin and from 1·95 to 4·23 mg. in the form of 4-pyridoxic acid calculated as pyridoxine. The total urinary excretion was thus 3 or 4 times the intake of the vitamin. The subjects were in negative N balance in 11 out of 15 experimental periods.

2. In 4 pregnant women similar results were obtained during the last trimester of pregnancy except that, possibly owing to higher intake of protein, the average daily intake of vitamin B_6 was 1·39 with range 0·68 to 2·01 mg. Total urinary excretion ranged from 1·83 to 5·43 mg. In the non-pregnant state 3 of the women had a lower intake of the vitamin.—L. Wills.

2353

TINELLI, G. and CALVARIO, M. L'indice xanturenico in affezioni neurologiche. [**The xanthurenic index in nervous disorders.**] *Acta vitaminol.*, 1955, **9,** 223–227. [Clin. Malat. Nerv., Univ. Bari.] French, English, German and Spanish summaries.

The xanthurenic acid index, which relates the amount of xanthurenic acid excreted in the urine to the amount of *l*-tryptophan given in a test dose of 0·1 g. per kg. bodyweight, was estimated in 15 epileptics and 21 patients with disturbances of the nervous system such as Friedrich's ataxia, Parkinsonism, chorea and Erb's progressive muscular dystrophy. The amount of xanthurenic acid excreted by normal subjects is not large enough to give an index greater than 1. Of the epileptics, 7 had an index greater than 1, and of the other patients 11; in the latter the raised index was not consistently associated with a certain type of disease. One epileptic and 4 other patients with high values for the index were given intramuscular injections of pyridoxine for from 4 to 7 days, and in every one of them the index fell to below 1.

Estimation of the index is regarded as a useful test for the state of vitamin B_6 nutrition.

[**Interactions of vitamin B_{12} with vitamin B_1 and riboflavin in subjects with and without liver disorders.**] *Acta vitaminol.*, 1955, **9,** 149–156. [Ist. Clin. Med. Gen., Univ. Bologna.] French, English, German and Spanish summaries.

Vitamin B_1 and riboflavin were estimated chemically in the urine of 10 patients with liver diseases and 10 without, before, during and after intramuscular injection of 500 μg. vitamin B_{12} daily for 3 days. The amount of both vitamins excreted before and after the treatment was less in the patients with liver disease. During treatment the amount of both vitamins in the urine rose greatly in those with liver disease and scarcely at all in those without. The highest values were obtained in response to the first and second injections; that after the third was less.—E. M. Hume.

WOKES, F., BADENOCH, J. and SINCLAIR, H. M. **Human dietary deficiency of vitamin B_{12}.** *Amer. J. Clin. Nutrit.*, 1955, **3,** 375–382. [Ovaltine Res. Labs., King's Langley, England.]

The evidence is collected about the development and nature of the vitamin B_{12} deficiency occurring in British Vegans, persons subsisting on a totally vegetarian diet. In a group of 117 British Vegans of all ages, deficiency signs were more frequent than in Dutch or American Vegans; it is pointed out that the British group had had a longer period on the diet and included more young people, and the mean percentage of their calories derived from protein was 7 compared with 9 and 10·4 in the Dutch and American groups, respectively. Signs of deficiency generally appeared after several years on the diet, but some subjects still had no signs after 5 years. The most frequent signs were

in the mouth, including sore tongue, paraesthesia and other nervous symptoms; fully developed subacute combined degeneration of the cord was described previously in a boy of 15 years (Abst. 1219, Vol. 25). Amenorrhoea and other menstrual disorders were present in 8 of 22 women aged from 15 to 45 years. About 20 per cent. of the subjects complained of pain in the back.

In Vegans in apparently good health, the only ones that it was possible to examine, the average serum value for vitamin B_{12} was 111 $\mu\mu$g. per ml. with a range from 45 to 193; in 9 subjects the value was below 100, which would be definite evidence of vitamin B_{12} deficiency. The red cell count plotted against the serum vitamin B_{12} value gave a curve which resembled that seen in cases of subacute combined degeneration rather than that found in pernicious anaemia. The mean corpuscular volume of the red cells was increased. There was evidence that tyrosine metabolism and the detoxication of cyanide, both processes in which vitamin B_{12} probably plays a part, were disturbed. The weights of the Vegan children showed the rate of growth to be subnormal. The findings support the view that a state of vitamin B_{12} deficiency exists in Vegans. It is pointed out that the diet must be almost completely lacking in the vitamin so that the variation in the serum vitamin B_{12} values must result from differences in the extent of synthesis and absorption of the vitamin from the gut.—L. Wills.

Wokes, F. and Picard, C. W. **The role of vitamin B_{12} in human nutrition.** *Amer. J. Clin. Nutrit.*, 1955, **3,** 383–390. [Ovaltine Res. Labs., King's Langley, England.]

Two hypotheses are outlined which might explain activity of vitamin B_{12} as animal-protein factor. Both involve the assumption that hydroxocobalamin (or aquocobalamin), and not cyanocobalamin, is the active form of vitamin B_{12}. The cyanide utilisation hypothesis postulates that, in the liver, hydroxocobalamin competes with rhodanese for CN. Rhodanese together with S donors converts CN to thiocyanate, most of which is excreted in the urine. Hydroxocobalamin takes up CN to form cyanocobalamin which may supply essential, one-carbon fragments for the synthesis of labile methyl groups. Liberation of the CN from cyanocobalamin regenerates hydroxocobalamin. The alternative sulphur-transfer hypothesis postulates the uptake of thiocyanate by hydroxocobalamin to form thiocyanatocobalamin, which might revert to cyanocobalamin, giving up its sulphur to an active intermediate X to form SX, which could be a precursor of essential sulphur-containing metabolites.—F. C. Aitken.

Saita, G., Moreo, L. and Sartorelli, E. La vitamina B_{12} nel saturnismo: azione sulla crasi ematica, sulla punteggiatura basofila e sul ricambio porfirinico. [**Vitamin B_{12} in lead poisoning: action on the blood picture, punctate basophilia and porphyrin metabolism.**] *Med. del Lavoro*, 1955, **46,** 404–410. [Clin. Lavoro L. Devoto, Univ. Milan.] English and German summaries.

It was previously found that liver extract was helpful in the anaemia of lead poisoning (*Med. del Lavoro*, 1955, **46,** 199). Nine subjects exposed to the risk of lead poisoning for not more than 4 years were treated 9 or 12 times with an injection of 500 μg. vitamin B_{12}, given every other day. There was a mean increase for all the patients of 10 per cent. for Hb and 12·5 per cent. for the red cell count, a result which was not as good as with liver extract. Reticulocytes showed a moderate increase. The number of cells with punctate basophilia decreased rapidly at first and then much more slowly. In the red blood cells, protoporphyrin increased at first and then decreased; coproporphyrin if present disappeared. In the urine coproporphyrin decreased. Vitamin B_{12} is considered to have a moderate normalising influence on porphyrin metabolism.—E. M. Hume.

Neber, H. Die Therapie verschiedener Hautkrankheiten, insbes. allergischer Genese, mit Vitamin B_{12}. [**Treatment of skin diseases, particularly those of allergic origin, with vitamin B_{12}.**] *Münch. med. Wochenschr.*, 1955, **97,** 1102–1103. [Osnabrücker Str. 17, Berlin-Charlottenburg 1.]

When skin conditions were treated with vitamin B_{12}, the best results were obtained with contact dermatitis and drug eczema, which frequently cleared up completely and rapidly. Considerable improvement was obtained also in acne vulgaris and in a single patient with lichen planus, but the results were disappointing with eczema of unknown origin and acne rosacea. The dose of vitamin B_{12} varied with the severity of the condition but an injection of 1000 μg. 2 or 3 times a week was frequently used.—L. Wills.

2362

ANNAND, J. C. **Growth factors as desensitizing agents.** *Practitioner*, 1955, **175**, 725–729. [Dundee.]

In 23 of 30 children suffering from allergy, including asthma, urticaria or eczema and periodic gastro-enteritis, there was great improvement, generally after a latent period of 4 or 5 weeks, when a daily oral supplement of liver or cyanocobalamin, with or without intrinsic factor, was given. Secondary infections tended to cause relapse, probably by reducing absorption.

L. Wills.

FOY, H., KONDI, A. and MANSON-BAHR, P. E. C. **Penicillin in megaloblastic anaemias of Africans. Effect on serum-vitamin B_{12} levels and absorption of radioactive vitamin B_{12}.** *Lancet*, 1955, **269**, 693–699. [Wellcome Trust Res. Labs.]

The patients with megaloblastic anaemia studied fell into 2 classes, in one of which there was a response to oral or parenteral penicillin or to oral vitamin B_{12}, and in the other to oral folic acid but not to penicillin or vitamin B_{12}. In the patients who responded to penicillin or vitamin B_{12} the serum vitamin B_{12} before treatment ranged from 20 to 100 $\mu\mu$g. per ml. but rose to normal after treatment. In contrast those who responded to folic acid had normal or high values for vitamin B_{12} in the serum, ranging from 300 to 1300 $\mu\mu$g. per ml. Treatment with penicillin of patients with values below 700 $\mu\mu$g. per ml. raised the value for vitamin B_{12} in the serum, but not for the red blood cells or Hb, but if the value for vitamin B_{12} in the serum was initially above 700 $\mu\mu$g. per ml. penicillin did not alter it. In both classes excretion of radio-active vitamin B_{12} was within normal limits. Free HCl was present in the gastric juice before and after histamine. A single patient with histamine-resistant achlorhydria and signs of subacute combined degeneration was diagnosed as having early pernicious anaemia. In the patients examined by gastroscopy, including the one diagnosed as pernicious anaemia, there was no evidence of gastric atrophy. The findings suggest that intrinsic factor was present in all the patients. The possible influence of the largely carbohydrate diet on the intestinal flora and the effect of penicillin on the flora and hence on the amount of vitamin B_{12} available are discussed.—L. Wills.

CONLEY, C. L. and KREVANS, J. R. **New developments in the diagnosis and treatment of pernicious anemia.** *Ann. Int. Med.*, 1955, **43**, 758–766. [Dept. Med., Johns Hopkins Univ., Baltimore, Md.] Interlingua summary.

Of 14 patients with pernicious anaemia presenting with severe subacute combined degeneration of the cord without appreciable anaemia, more than half had been treated earlier with multiple vitamin preparations containing folic acid. Such treatment in mild anaemia is dangerous. Diagnosis in doubtful cases was made by Schilling's test for the urinary excretion of radio-activity after an oral dose of radio-active vitamin B_{12} followed by a large parenteral flushing dose of inert vitamin B_{12}. The most reliable treatment is considered to be injection of vitamin B_{12} since, even after very large oral doses of the vitamin, the serum value remains subnormal although a complete haematological remission may have been produced and maintained for many months.—L. Wills.

2368

KLAYMAN, M. I. and BRANDBORG, L. **Clinical application of cobalt^{60}-labeled vitamin B_{12} urine test.** *New Engl. J. Med.*, 1955, **253**, 808–812. [Dept. Med., Univ. Chicago, Ill.]

The findings of other workers that, in pernicious anaemia and after total gastrectomy, only insignificant amounts of radio-activity appear in the urine after an oral test dose of radio-active vitamin B_{12} followed by a flushing parenteral dose of inactive vitamin B_{12}, were confirmed. In addition, 3 patients not suffering from either condition excreted only insignificant amounts of radio-activity after the test dose; in 2 of them the failure was apparently due to faulty absorption, caused by removal of a large part of the small intestine in one and by diffuse gastric carcinoma in the other; in the third the failure was not explained. Other patients showed small excretions of which the significance was not clear.

L. Wills.

HÖPKER, W. Eiweisszufuhr und Erhaltungsdosis bei Perniciosakranken. [**Protein supply and maintenance dose for patients with pernicious anaemia.**] *Klin. Wochenschr.*, 1955, **33**, 1002–1006. [Med. Klin., Univ. Greifswald.]

The mean haematological findings in a group of 38 patients with pernicious anaemia, who received in addition to the basic treatment with parenteral liver extract a supplement of 0·5 litre whole milk daily and 250 g. cheese weekly, did not differ significantly from those for a similar group of patients given the basic treatment only. The mean daily maintenance dose of vitamin B_{12} for all the patients during 9 months was 2·3 μg. with range 0·5 to 4·5.—L. Wills.

2370

MONTO, R. W. and REBUCK, J. W. **Observations on the mechanism of intranasal absorption of vitamin B_{12} in pernicious anemia.** *Blood, J. Hematol.*, 1955, **10**, 1151–1155. [Div. Haematol., Dept. Labs., Henry Ford Hosp., Detroit, Mich.]

Crystalline vitamin B_{12}, given intranasally in doses of 100 μg. in saline solution or as a lactose powder, produced a haematological response in 32 patients in relapse and when given every 3 or 4 weeks maintained 55 patients in satisfactory remission. Nasal washings obtained from a normal subject after the instillation of 150 μg. vitamin B_{12} were given by stomach tube to a patient in relapse. There was no response, but the same patient responded later to 150 μg. vitamin B_{12} when it was placed on the nasal mucosa. The opinion is offered that the vitamin is absorbed directly and not after combination with intrinsic factor.—L. Wills.

REISNER, E. H. (Jr.), WEINER, L., SCHITTONE, M. T. and HENCK, E. A. **Oral treatment of pernicious anemia with vitamin B_{12} without intrinsic factor.** *New Engl. J. Med.*, 1955, **253**, 502–506. [Div. Haematol., Dept. Med., Postgrad. Med. Sch., Univ. New York.]

Of 43 patients with pernicious anaemia the majority were brought into and maintained in satisfactory remission for from 12 to 28 months on an oral dose of 1 mg. vitamin B_{12} given once or twice a week or every 2 weeks. The cost was materially less than for injections.—L. Wills.

2372

GERNER, G. and HENNING, N. Das Vitamin-B_{12}-Bindungsvermögen des menschlichen Magensaftes in Beziehung zum histologischen Bild der Fundusschleimhaut. [**Vitamin-B_{12}-binding capacity of human gastric juice in relation to the histological picture of the fundus mucosa.**] *Gastroenterologia*, 1955, **84**, 103–118. [Med. Klin., Univ. Erlangen.] English and French summaries.

The methods used are described; the vitamin B_{12} of the gastric juice was estimated microbiologically with *Euglena gracilis*. Biopsy material was obtained from the lower third of the fundus. In 46 subjects the vitamin B_{12} content of the fasting juice was related to the amount of free acid, regardless of the clinical condition of the subject. With normal acidity the mean value per ml. was for free vitamin B_{12} 4·66 $\mu\mu$g. with range 0·10 to 37·4 and for total vitamin B_{12} 82·70 $\mu\mu$g. with range 0·48 to 208·0. With hyperacidity both mean values were increased to 11·53 and 130·62, respectively. In subacidity and anacidity, respectively, the mean free value was increased to 26·05 and 50·55, though the mean value for total vitamin B_{12} remained the same as with normal acidity. In 28 subjects with no gastric symptoms the mean value for free vitamin B_{12} was 6·45 with range 0·00 to 66·40; the mean for total vitamin B_{12} was 118·45 with range 0·48 to 460·00, and the mean binding capacity in 35 min. 122·39 $\mu\mu$g. per ml. with range 0·00 to 387·40. In 11 subjects with histologically confirmed chronic superficial gastritis the corresponding figures were 10·45, 70·25 and 216·32; the last value was not significantly greater than the normal mean binding capacity. In 10 patients with histologically confirmed atrophic gastritis associated with anacidity, of whom 2 had pernicious anaemia, the corresponding values were 49·01, 96·69 and 26·04, the last value being significantly below normal. After parenteral treatment of the pernicious anæmia patients with vitamin B_{12} there was a great rise in the free vitamin value. After histamine injection there was a slight rise in the vitamin-B_{12}-binding capacity of

the gastric juice in normal subjects but a decrease in patients with gastritis. [There are discrepancies between text and tables and arithmetical errors seem to occur.]—L. Wills.

ŁOPOREK, M., BISHOP, R. C., NELSON, N. A. and BETHELL, F. H. (with HAINES, M. T. and KLIMOVICH, J.) **Urinary excretion of Co^{60}-vitamin B_{12} as a test for effectiveness of intrinsic factor preparations.** *J. Lab. Clin. Med.*, 1955, **46,** 665–670. [Thomas Henry Simpson Mem. Inst. Med. Res., Univ. Michigan, Ann Arbor.]

Pernicious anaemia patients in remission were given an oral dose of ^{60}Co vitamin B_{12}, and the percentage of it excreted in the urine in 24 hr. was estimated by Schilling's technique. In most of the subjects the excretion was about $0{\cdot}5 \pm 0{\cdot}2$ per cent. of a standard dose of 0·05 μC. ^{60}Co, but in a certain number the excretion was high, so that a control test of this kind must always be made before a patient is used to test a preparation of intrinsic factor. For tests of intrinsic factor suitable subjects were given, with the radio-active ^{60}Co, a given quantity of the preparation of intrinsic factor, and the output of radio-activity was measured and compared with that after radio-active ^{60}Co alone. Some preparations showed a maximum concentration beyond which their activity decreased, possibly on account of the presence of inhibitory material in the preparation, or because there is an optimum ratio of intrinsic factor to vitamin B_{12}. Results with preparations of known potency and with normal gastric juice suggested that excretion of 2·5 per cent. of the dose was the minimum proportion which could be taken to indicate activity.—L. Wills.

Vitamin C

2375

LEVINE, V. E. **Scurvy in Nebraska: 2. The epidemic of scurvy among the Indians of the Omaha tribe, 1845-1846.** *Amer. J. Digest. Dis.*, 1955, **22,** 294–295. [Dept. Biol. Chem. Nutrit., Sch. Med., Creighton Univ., Omaha 2, Nebr.]

HAYNES, R. C. (Jr.) and SCHEID, H. L. **Lack of effect of ascorbic acid on hydrocortisone metabolism in man.** *J. Clin. Endocrinol.*, 1955, **15,** 1257–1261. [U.S. Army Med. Nutrit. Lab., Fitzsimons Army Hosp., Denver, Colo.]

Measurement of hydrocortisone in plasma and of 17-hydroxycorticoids and 17-ketosteroids in urine from 5 normal men showed that large doses of ascorbic acid did not significantly affect the metabolism of hydrocortisone given by mouth.

A. Hepburn.

2377

ROWLANDS, R., KAMASASTRI, P. V., JOSEPH, M. and ROW, M. **Studies in ascorbic acid.** *Indian J. Med. Res.*, 1955, **43,** 627–635. [Christian Med. Coll. Hosp., Vellore.]

The average total ascorbic acid concentration in whole blood from 43 normal adults, 100 out-patients with gastric disturbances and 100 miscellaneous patients was 0·88, 0·42 and 0·41 mg. per 100 ml., respectively. Two, 33 and 32 from the respective groups had less than 0·25 mg. per 100 ml.

Ascorbic acid saturation tests were made on 43 normal subjects. There was good correlation between the number of days to reach saturation, the kind of diet and the initial blood value for ascorbic acid. It was, therefore, thought that saturation tests provided little additional information, and that the dietary history and blood ascorbic acid value were sufficient for survey work.

A. Hepburn.

2378

MEL'NIKOV, A. A. Vliyanie vitamina C khloristogo kal'tziya na reaktivnost sosudov i vodnyi obmen pri nefritakh. [**The influence of vitamin C and calcium chloride on vascular reactivity and water metabolism in patients with nephritis.**] *Klin. Med., Mosk.*, 1955, **33,** No. 4, 85–86.

The cold pressure and nicotine test revealed that a continuous drip of calcium chloride had a pressor effect on the vascular system of patients with chronic nephritis. Injection of from 2 to 3 ml. of a 10 per cent. solution of ascorbic acid had an antipressor effect. Calcium chloride stimulated diuresis. Ascorbic acid alone inhibited it, but in the presence of calcium chloride given by continuous drip it stimulated diuresis. In chronic nephritis administration of ascorbic acid over a long period or even permanently is recommended in a dose of 60 mg. daily, with calcium chloride only when the disease is severe, or when vitamin C is ineffective.—E. S. Fountain.

2379

IKEUCHI, M. **Biochemical studies on D-arabo-ascorbic acid in vitamin C deficiency.** *J. Vitaminol., Japan*, 1955, **1,** 193–199. [Lab.

Biochem., Tokyo Jikeikai Sch. Med., Minato-ku.]

When human subjects suffering from vitamin C deficiency due to malnutrition were given araboascorbic acid by intravenous injection they excreted 10 to 15 times as much reduced araboascorbic acid in the urine as the reduced ascorbic acid excreted by similar subjects receiving ascorbic acid. After 6 hr., 5 per cent. of total ascorbic acid was excreted and more than 50 per cent. of total araboascorbic acid. The antiscorbutic activity of araboascorbic acid was therefore considered to be trifling in comparison with that of ascorbic acid.—A. Hepburn.

Other Vitamins

HAUSCHILD, W. Schockverhütung durch Rutin. [**Protection from shock with rutin.**] *Münch. med. Wochenschr.*, 1955, **97**, 1101–1102. [Chirurg. Klin. Charité, Univ. Berlin.]

In view of satisfactory results reported in animal experiments, the protective effect of rutin against anaphylactic shock was investigated in 10 patients undergoing tests for serum treatment of leucaemia or malignant metastases. The patients were given from 6 to 66 injections of rabbit serum by different routes within from 15 to 77 days. When rutin was injected 5 min. before the serum, anaphylactic reactions were prevented or minimised. Small local reactions sometimes occurred but quickly subsided. The possibility of using rutin as a protection against shock in many forms of serum treatment is suggested.

SAITA, G., GATTONI, L. and SARTORELLI, E. Le modificazioni dell'attività protrombinica nel saturnismo. Azione della vitamina K. [**Modifications of prothrombin activity in lead poisoning. Effect of vitamin K.**] *Med. del Lavoro*, 1955, **46**, 541–548. [Clin. Lavoro L. Devoto, Univ. Milan.] English and German summaries.

The prothrombin time of Quick was estimated and the concentration calculated in 39 subjects with lead poisoning, 15 of them with acute lead colic, and 24 of them in a chronic state. In 22 of them factor V and factor VII, which contribute to the conversion of prothrombin to thrombin, were estimated separately. In the 15 subjects with acute colic, the prothrombin concentration was normal in 5 and low in 10. In the 24 chronic cases, it was normal in 11 and low in 13. Deficiency of factor VII was always present if the prothrombin value was low, but might exist also with a normal value. Factor V was little affected in any of the subjects. Blood values for bilirubin were somewhat raised, and liver damage was therefore thought probable. As test of liver function, prothrombin was estimated in the blood before and 3, 5 and 24 hr. after an intravenous injection of 10 mg. vitamin K in 7 of the acute and 10 of the chronic cases. In each group the prothrombin value returned to normal within 5 hr. in some and within 24 hr. in others, but in 2 of the chronic cases the value returned to normal only within 24 hr. after 50 mg. had been injected. It is considered that damage to liver parenchyma existed in proportion to the difficulty of restoring the prothrombin value to normal, but that it was never severe.—E. M. Hume.

SIDDIQUI, A. H. **Fluorosis in Nalgonda District, Hyderabad-Deccan.** *Brit. Med. J.*, 1955, ii, 1408–1413. [Osmania Med. Coll., Hyderabad-Deccan.]

Three villages about 50 miles from the city of Hyderabad with populations of 95, 813 and 1100 were chosen. The general standard of living of the people was poor and the ranges for F content of water from their wells were, respectively, 9·2 to 11·8, 5·5 to 6·8 and 2·5 to 7·5 p.p.m. Clinical findings are tabulated for 32 persons in whom there were neurological signs and radiological, haematological and biochemical studies also are reported.

The findings were in agreement with the high intakes of F by the patients. The physical strain of carrying loads on their heads is thought to have caused changes in the skull and cervical spine, areas which have seldom been reported as affected. One patient was excreting 3·4 p.p.m. F in urine 10 years after he had left the endemic area. In a chicken with the disease the bones were found to contain 37·8 mg. F per 100 g. dry matter.—D. Harvey.

POISONS: PATHOGENIC ORGANISMS: FOOD LAWS

2391

PAUL TRÜB, C. L. and REPLOH, H. Erkrankungen durch Lebensmittel in der Nachkriegszeit (1946–1950) im Lande Nordrhein-Westfalen. [**Illnesses due to food in the post-war period, 1946-50, in Nordrhein-Westphalia.**] *Arch. Hyg., Berlin*, 1954, **138**, 98–129. [Medizinalabt. Bezirksregierung, Düsseldorf.]

Outbreaks of food poisoning are considered under the headings typical bacterial infections, atypical bacterial infections and poisoning with chemical substances with which are included beans, potatoes in an inedible state and genuine chemical poisons gaining accidental access to food or water. The number of officially registered cases analysed was 5858. Suggestions are made about amending the laws.—E. M. Hume.

2392

[COMMISSION FOR NUTRITION, SWITZERLAND.] 3. Tätigkeitsbericht der Eidg. Kommission für Volksernährung, Lebensmittelgesetzgebung und -kontrolle zu Handen des Eidg. Departementes des Innern umfassend die Jahre 1953 und 1954. [**3rd Report of the Commission for Nutrition, Food laws and Food Control to the Swiss Federal Department of the Interior for the years 1953 and 1954.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46**, 261–274; in French, 275–287.

The main matters dealt with by the Commission were: milk, bacteriological improvement and elimination of tuberculous cows (findings embodied in new laws); bread, reconsideration of extraction rate in connection with dental caries, since dentists declare that school entrants' teeth, which improved during the war, are now worse than before it; health of mountain population, plans for 3-year small-scale surveys in restricted areas where nutritional deficiencies are known to occur; additions to foods, (1) addition of vitamin D to milk for children recommended, but not general addition of vitamins to milk, or to spirits or tobacco, (2) fluorine to prevent caries, group of experts to consider whether addition of F to water, salt or other foods is desirable in Switzerland, regular taking of fluoride tablets by pregnant women and children under 11 suggested as an interim measure, (3) anti-oxidants, those occurring naturally in foods permissible unless in excess, and a few tested synthetic ones where spoilage would otherwise be inevitable, (4) colours, encouragement of the use of the 12 synthetic colours on the international list first set up at Bad Godesburg in May 1954. Steps were also taken towards initiation of studies of the possible biological effects of insecticides and artificial manures.—W. M. Deans.

Three patients allergic to fatty foods were treated successfully with a low-fat diet and a ketocholanic acid preparation, Triketol.—F. C. Aitken.

THERAPEUTIC AND PREVENTIVE DIETETICS

GENERAL

2395

MOELLER, H. C., GROSSMAN, M. I., PALM, L., CUSHING, A., STADLER, J. B. and BECKER, G. H. **A study of two intravenous fat emulsions in human subjects.** *J. Lab. Clin. Med.*, 1955, **46**, 450–460. [U.S. Army Med. Nutrit. Lab., Denver, Colo.]

Febrile responses in human subjects and rabbits to infusions of cottonseed oil and olive oil emulsions were recorded and expressed quantitatively as fever indices. There was no significant difference in fever index between the emulsions.

Biochemical and haematological studies in the human subjects showed that the magnitude of the febrile response was not well correlated with optical density, total fatty acid, free fatty acid or lysozyme of the serum or with changes in leukocytosis.

Concentration of free fatty acid in serum rose during the lipaemia which was induced by infusion of fat emulsion.—F. C. Aitken.

JACKSON, W. P. U. and LINDER, G. C. **The clinical and metabolic effects of massive intestinal resections.** *Acta med. scand.*, 1955, **102**, Suppl. 306, 96–106. [Dept. Med., Univ. Cape Town.]

Two cases are described. In one patient who died 3½ years after operation there were signs of poor absorption, specific deficiencies and mental disorder but no anaemia or tetany; a fall in plasma protein occurred late. The picture was of under-nutrition rather than the jejuno-ileal insufficiency syndrome (Bennett and Hardwick, Abst. 3068, Vol. 10). In the other patient, who made excellent progress, there was no evidence of poor absorption 5 years after operation.—F. C. Aitken.

2410

BERG, G. and FRENGER, W. Verdauungs- und Resorptionsstörungen nach Ausschaltung grösserer Abschnitte des Dünndarms.

[Disturbances of digestion and absorption after by-passing of large parts of the small intestine.] *Deutsch. med. Wochenschr.*, 1955, **80,** 1799–1802. [Med. Klin., Univ. Erlangen.]

Six patients are described in whom digestive disturbances developed after surgical treatment had considerably reduced the functional length of the small intestine. All had frequent fluid stools. Digestion and absorption were reduced and all the patients were emaciated.

Five had low serum albumin, 2 with oedema, though 2 had normal total serum protein. The clinical condition suggested deficiency of all the main dietary components and of Fe, but, although 2 patients had osteoporosis and 2 had pigmented skin, no clear sign of mineral or vitamin deficiency was found.—D. Duncan.

2411

FRAZER, A. C. **Steatorrhoea.** *Brit. Med. J.*, 1955, ii, 805–809. [Dept. Pharmacol., Univ. Birmingham.]

Steatorrhoea is defined as the passage of fluid or semi-fluid, bulky, pale, fatty and usually offensive stools. The passage of formed stools of abnormally high fat content should not be called steatorrhoea. The relation of steatorrhoea to faulty intestinal absorption is indicated and the defects of absorption are classified as pancreatogenous, hepatogenous and enterogenous. Enterogenous conditions are differentiated as gluten-induced enteropathy, tropical sprue or anastomatic syndromes. Dietary treatment to reduce bacterial activity in the intestine and other specific measures, such as administration of pancreatic enzymes, bile salts, folic acid or a gluten-free diet, are described.

F. C. Aitken.

2412

HAWKINS, C. F. **The treatment of steatorrhoea.** *Postgrad. Med. J.*, 1955, **31,** 552–557. [Dept. Clin. Med., Univ. Birmingham.]

Some patients with steatorrhoea respond to treatment with a gluten-free diet. For those who do not the diet recommended is one high in protein, 100 to 120 g., and low in fat, 50 g. or less.

Anaemia, osteomalacia and tetany, dehydration and electrolyte disturbance may occur with steatorrhoea. The treatment of these conditions is outlined, together with the method of relieving diarrhoea and the use of adrenal cortical hormone.

An addendum gives instructions to patients on a gluten-free diet.—F. C. Aitken.

FRIEDLANDER, P. H. and GORVY, V. **Steatorrhoea. A review of 40 patients, with particular reference to diagnosis.** *Brit. Med. J.*, 1955, ii, 809–812. [Middlesex Hosp., London.]

The term steatorrhoea is used when the fat in the faeces exceeds 10 per cent. of the amount of fat ingested each day. Steatorrhoea is classified as primary, which includes idiopathic steatorrhoea, tropical sprue and coeliac disease, or secondary, where a lesion that might cause faulty fat absorption has been diagnosed. Of the 40 cases reviewed 13 were primary, 23 were secondary and in 4 the type was uncertain. The bases of the differential diagnosis are discussed.—F. C. Aitken.

VAN DE KAMER, J. H. and WEIJERS, H. A. **Coeliac disease. 5. Some experiments on the cause of the harmful effect of wheat gliadin.** *Acta paediat.*, 1955, **44,** 465–469. [Central Inst. Nutrit. Res. T.N.O., Utrecht.] French, German and Spanish summaries.

For part 4 see Title 1189, Vol. 24.

The possibility was investigated that the harmful effect of wheat gliadin in coeliac disease was due to its high glutamine content. Two patients in good condition and on a wheat-free diet were given glutamine in doses of 2 g. rising to 4 g. daily. These amounts, equivalent to 125 to 250 g. wheat flour, had no adverse effect. Gliadin was boiled with *N* HCl for 45 min., a procedure which converted 90 per cent. of the glutamine into glutamic acid and NH_3 but affected the peptide bonds only slightly. This preparation was given in place of gliadin to 2 patients showing the toxic effects of wheat protein. One recovered completely. The second and more severely ill recovered when the gliadin preparation given had been boiled for 2 hr. and only 3 per cent. of the glutamine remained unchanged.

The experiment suggested that glutamine bound in gliadin, but not free glutamine, was the cause of the harmful effect of wheat gliadin. The ratio amide N : non-amide N in several foods was estimated. All harmless proteins had ratios of 11 or less; harmful protein had higher values, such as wheat flour 23, wheat gliadin 30.—F. C. Aitken.

HOLLER, G. Untersuchungen und Erfahrungen mit "Cellumikromoor". **[Studies and results with "Cellumikromoor".]** *Gastroenterologia*, 1955, **83,** 343–348. [Allg. Krankenhaus, Baden, near Vienna.] English and French summaries.

A mixture of carboxymethylcellulose with powdered peat is suggested for treatment of digestive tract disorders.

2417

FERRER, F. P. and BOYD, L. J. **Effect of yogurt with prune whip on constipation.** *Amer. J. Digest. Dis.*, 1955, **22**, 272–273. [New York Med. Coll., Metropol. Hosp. Res. Unit, Welfare Island 17.]

Prune whip yogurt was given as a night feeding in place of laxative to 194 elderly patients. Twenty-eight patients refused to take it. Of the remainder only 7 had to resort to laxatives during the experiment. Of the patients given the yogurt 91 were diabetic and the supplement, which supplied 247 Cal., raised blood sugar in 22 per cent. of them. Substitution of a milk-prune whip mixture supplying 141 Cal. raised blood sugar in nearly half of the diabetics. [There are several arithmetical errors.]

THYROID DISEASE

2418

BRÜGEL, H. Erhöhte Jodidgier der Schilddrüse ohne Thyreotoxikose. [**High iodine turnover in the thyroid gland without thyrotoxicosis.**] *Deutsch. med. Wochenschr.*, 1955, **80**, 1305–1311. [Med. Klin., Städt. Krankenhaus Stuttgart, Bad Cannstatt.]

The 24-hr. iodine uptake of the thyroid was studied in more than 2000 patients. A few were found in whom the uptake was more than 50 per cent. above normal, but who had no clinical evidence of thyrotoxicosis. Their condition was attributed to "vegetative dystonia". In 15 of them treatment for from 7 to 10 days with thyroid extract or thyroxine resulted in uptake of I being normal at the next test. In 3 others 1 mg. I daily for 10 days had no effect, but thyroid extract was effective. In 3 patients with thyrotoxicosis, thyroid extract given for from 7 to 10 days did not reduce uptake of I, but had no untoward effect.

ANAEMIA

2419

JANELE, J. **Bone marrow and anemia in premature infants.** *Ann. paediat.*, 1955, **185**, 257–279. [2. Paediat. Clin., Charles Univ., Prague.] German and French summaries.

Bone marrow was withdrawn during the first 72 hr. of life from 100 premature infants of birth-weight less than 2500 g. The low cell count of the smears, the low total number of nucleated cells and high myeloid : erythroid ratio on the third day of life indicated insufficient erythropoiesis. It is concluded that, at this stage, treatment with Fe is useless.—F. C. Aitken.

2420

HEIMENDINGER, H. and UNDRITZ, E. Ist das tiefe Absinken der Hämoglobinwerte im Kindesalter physiologisch oder Ausdruck eines Eisenmangels ? [**Is the deep fall of the haemoglobin value in childhood physiological or the expression of iron deficiency ?**] *Schweiz. med. Wochenschr.*, 1955, **85**, 919–920 ; 933–936. [Kinderspital, Basle.]

In both sexes the Hb value is usually high at birth and then falls rapidly, reaching a minimum between 1 and 3 years of age, and slowly rises again to puberty, after which the values for boys are higher than for girls.

Hb was estimated in the blood of 158 boys and 87 girls aged from 17 days to 15 years in 2 homes in Basle, one for very poor, and one for somewhat less poor, children. Ferrogluconate (Ferronicum, Sandoz) to supply about 2 mg. Fe per kg. body-weight daily was given to 141 of them for 4 or 5 months. Before treatment the curve of Hb values at different ages showed the early low values and subsequently rose slowly. On treatment most of the children showed rapid increase of Hb with better appetite, better colour and good resistance to colds, catarrh and influenza. Children with normal values showed no increase ; the few children with influenza or an allergic condition failed to respond, but the failure was usually temporary. Six bed-wetters were cured while receiving Fe, but relapsed when it was withdrawn. They asked for the treatment to be resumed. Initial disturbances caused by the treatment, such as diarrhoea and loss of appetite, were not difficult to overcome.

It is concluded that the low Hb values so frequent in childhood are caused by inadequate intake of Fe. If a diet richer in Fe is insufficient to combat the anaemia, treatment with Fe should be given for 6 weeks in summer and for 2 or 3 months in winter.

2421

DAVIDSON, W. M. B. and MARKSON, J. L. **The gastric mucosa in iron-deficiency anaemia.** *Lancet*, 1955, **269**, 639–643. [Stobhill Gen. Hosp., Glasgow.]

Gastric biopsy specimens were obtained from 42 patients with Fe deficiency anaemia and from 31 control patients with other disorders. The mucosa was histologically abnormal in 74 per cent. of the anaemic and in 29 per cent. of the control patients. Achlorhydria was found in 48 per cent. of anaemic and in 13 per cent. of control patients. The mucosa was abnormal in all but 1 patient with achlorhydria. Of patients without achlorhydria 50 per cent. of those with anaemia and 18 per cent. of controls had abnormal mucosa. This suggests that achlorhydria develops after Fe-deficiency anaemia has become established.—F. C. Aitken.

RAINER, O. and ZOLINER, S. Die perorale Eisenresorption nach totaler Gastrectomie. [**The absorption of iron given by mouth after total gastrectomy.**] *Wien. klin. Wochenschr.*, 1955, **67**, 735–737. [2. Med. Abt., Landeskrankenhaus, Klagenfurt.]

In 12 patients 4 years to 16 weeks after total gastrectomy there was no sign of failure to absorb Fe, as judged by balance estimations. The results were within the normal range for the dose of Fe given orally, though the fasting value for Fe in serum was low in some of the patients, and 2 were certainly anaemic. In 5 other similar patients, 1 with normal and 4 with low fasting values for serum Fe, the rise after the test dose exceeded normal, and in 3 was high enough to be evidence for definite Fe deficiency. One of these Fe-deficiency subjects was severely anaemic and the serum showed a high unsaturated Fe-binding capacity. It is suggested that the results show that total gastrectomy does not of itself interfere with absorption of Fe and that the Fe-deficiency anaemia sometimes present is due to the atrophic enteritis that develops sooner or later in this type of patient.—L. Wills.

ARIAS VALLEJO, E. La anemia de los individuos con estómago en cascada. [**Anaemia in subjects with cascade stomach.**] *Rev. española Enferm. Apar. digest. Nutricion*, 1955, **14**, 621–630. English summary.

Of 56 patients with the cascade form of hour-glass stomach, 27 had hypochromic microcytic anaemia and 2 had hyperchromic macrocytic anaemia. The hypochromic form responded well to treatment with Fe. Both patients with hyperchromic anaemia had histamine-resistant achlorhydria and megaloblastic bone marrow and responded to treatment with liver. The hypochromic form could sometimes be traced to haemorrhage, but in other patients it seemed to be due to faulty absorption of Fe.—D. Duncan.

TASKER, P. W. G. **Studies of the nutritional anaemias of Malaya: the prevalence of iron deficiency.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1955, **49**, 478–482. [Inst. Med. Res., Kuala Lumpur.]

The patients, who numbered 314, were mainly Southern Indians and Chinese of the poorer classes attending as out-patients. Many were later admitted to hospital. Estimations were made of serum Fe, Hb, and packed cell volume.

When Hb was above 14 g. per 100 ml. mean serum Fe with standard deviation was 145 ± 41 μg. per 100 ml.; as it fell, so also did serum Fe, and when Hb was below 7 g. serum Fe remained nearly constant with a mean value of 52 ± 16 μg. As mean corpuscular Hb concentration (MCHC) fell from 36 to 29 per cent. so too did serum Fe; below that level serum Fe was again constant at less than 50 μg. When plotted against Hb the curve for MCHC fell as Hb diminished and reached a minimum of about 22 per cent.

The data show that Fe deficiency is a frequent cause of nutritional anaemia and that an Hb value of 6 g. per 100 ml. is the critical one at which patients look very ill and require treatment in hospital.—D. Harvey.

2425

VENKATESWARA RAO, S. **Nutritional anaemia.** *Antiseptic*, 1955, **52**, 697–706. [Osmania Hosp., Hyderabad-Deccan.]

One medical unit of a hospital admitted in $3\frac{1}{2}$ years 147 adults with anaemia which was not secondary to some other disease. Of these 103 had nutritional anaemia and in 41 of these the condition was associated with hypoproteinaemia. Treatment was with improved diet, liver injections and vitamins and Fe by mouth and response was good in 85 patients.—F. C. Aitken.

2426

BERRY, C. G. **Anaemia of pregnancy in Africans of Lagos.** *Brit. Med. J.*, 1955, ii, 819–823. [Dept. Pathol. (Weir Res.), St. James' Hosp., London, S.W.12.]

Details are given of clinical and laboratory findings for 30 women taken at random from those admitted to hospital for treatment of anaemia. In most patients the anaemia was macrocytic and hypochromic. The results of treating 13 with vitamin B_{12}, 9 during pregnancy and 4 immediately after delivery, are also presented. In the first of these groups there was a response in 7, rapid in 4 patients and less so in 3; in the second group 2 patients failed to respond and later died.

The findings are discussed.—D. Harvey.

2427

WOODS, J. D. and RYMER, J. J. H. **Pernicious anaemia in the South African Bantu.** *Lancet*, 1955, **269**, 1274 – 1275. [Edendale Hosp., Pietermaritzburg.]

Pernicious anaemia with subacute combined degeneration of the spinal cord is described in a Bantu woman. The neurological disorder worsened on treatment with folic acid and was relieved by vitamin B_{12}.—F. C. Aitken.

2428

HOLLINGSWORTH, J. W. and ADAMS, F. M. **Megaloblastic anemia of pregnancy in two sisters. Case reports and an investigation of the**

hemolytic mechanism by means of erythrocyte survival studies. *Blood, J. Hematol.*, 1955, **10,** 933–940. [Dept. Haematol., Army Med. Serv. Grad. Sch., Washington, D.C.]

The patients were treated successfully with folic acid. Before treatment, and 10 and 48 days after the beginning of folic acid therapy, red cells from the patients were labelled with radio-active Cr and introduced into normal subjects. Curves of decreasing radio-activity were steeper than normal, especially for cells obtained before, or after only 10 days', treatment. The possible significance of these findings is discussed.—F. C. Aitken.

OTHER CONDITIONS

2429

VENKATACHALAM, P. S., SRIKANTIA, S. G. and GOPALAN, C. **Changes in body composition during nutritional rehabilitation.** *Indian J. Med. Res.*, 1955, **43,** 511–516. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Of 8 malnourished subjects studied, aged from 14 to 45 years, 3 had clinical oedema and 5 were emaciated and had no oedema. The oedematous patients were given a diet supplying 3300 Cal. with 119 g. protein and the others 2900 Cal. with 84 g. protein. Changes in bodyweight were recorded during rehabilitation for up to 88 days and N balance studies were made ; total body fluids were estimated by the urea-dilution method and total body solids were calculated.

Patients showing nutritional oedema lost weight rapidly during the first few days ; thereafter their weight remained stationary. Changes in bodyweight tended to give a misleading picture of the amount of total solids laid down. In all but one the increase in body solids was greater than the amount of protein retained. Since the patients were visibly accumulating fat, it was uncertain whether all the protein retained was built into the tissues. Clinical changes during rehabilitation were similar to those previously noted by other workers.—J. S. Thomson.

Results are presented of the treatment of 168 obese patients at a community nutrition clinic. In only half of the patients was treatment worth while. Its failure appeared to be directly related to emotional instability.—F. C. Aitken.

2433

FRYER, J. H., MOORE, N. S., WILLIAMS, H. H. and YOUNG, C. M. **Satiety values of isocaloric diets for reducing, with special reference to the glucostatic theory of appetite control.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 868–875. [Sch. Nutrit., Cornell Univ., Ithaca, N.Y.]

Twelve healthy men, aged from 19 to 29 and overweight, were given reducing diets providing 1800 Cal. daily with different amounts of carbohydrate, fat and protein. At the end of a 3-week period of adaptation to each diet capillary and venous blood samples were taken from each subject at intervals throughout a full day. Sugar was estimated and the difference between levels in the samples, Δ-glucose, was taken as a measure of available glucose.

The satiety values of the 3 diets were compared. Opinions differed but, in general, the low-protein diets were thought to be least satisfying. The mean values for blood sugar on the different diets and the effect on the glucose curves of increasing the energy from 1800 to 3000 Cal. daily were studied. No correlation was found between the capillary, venous or Δ-glucose level and the satiety value of the diets. The diet with the greatest satiety value produced the lowest mean levels of blood glucose and Δ-glucose. Instances occurred of complete lack of hunger in the presence of negligible or even apparently negative levels of Δ-glucose ; in 2 subjects hunger occurred in the presence of substantially positive values for Δ-glucose.

The mean loss of weight during the 9 weeks of experiment on the diets with 1800 Cal. was 23·6 lb.

2435

BRONTE-STEWART, B., KEYS, A. and BROCK, J. F. (with MOODIE, A. D., KEYS, M. H. and ANTONIS, A.) **Serum-cholesterol, diet, and coronary heart-disease. An inter-racial survey in the Cape Peninsula.** *Lancet*, 1955, **269**, 1103–1108. [Cape Town.]

Data, derived in part from a wider study, are presented for 364 men who were free from disease and who belonged in almost equal numbers to the 3 communities, Bantu, Coloured and European, living in Cape Town. The men were between 40 and 58 years of age and were working in industry. Their diets were studied and a semi-quantitative assessment was made of their intakes of animal and vegetable fats. Clinical histories were collected and the final number of subjects was reached after exclusion of those with indications of coronary atherosclerosis; they numbered 1, 5 and 9 in the Bantu, Coloured and European groups, respectively.

The mean values for data on blood samples from the groups in that same order were: total cholesterol 166·3 ± 47·2, 204·1 ± 54·8 and 234·0 ± 52·9 mg. per 100 ml.; percentage of total cholesterol in β-lipoproteins, 71·9 ± 10·1, 76·8 ± 9·9 and 82·6 ± 7·1. The absolute levels in the α-lipoprotein fraction were almost identical for the groups, about 40 mg. cholesterol per 100 ml.

When the subjects in each community were grouped according to income it was found that, with rise in income, intake of vegetable fat was unaffected; intake of animal fat and the level of cholesterol in serum rose as income increased. For coronary heart disease in Cape Town the mortality rate of Europeans is more than twice that of Cape Coloured; among Bantu such disease is exceedingly rare as a cause of death.

The findings for this localised population are considered to support the hypothesis that these blood changes influence the pathogenesis of coronary heart disease.—D. Harvey.

SIEDE, W. Zur Frage der Behandlung von Leberkrankheiten mit Aminosäuren. [**Treatment of liver disorders with amino-acids.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1955, **15**, 188–197. [Med. Klin., Diakonissenkrankenhaus Elisabethenstift, Darmstadt.]

The treatment of chronic liver disorders with amino-acids is discussed with references to the literature. Administration of amino-acids singly, *e.g.*, methionine, is considered undesirable. Curds are a good source, or for severe cases protein hydrolysates by mouth or stomach tube rather than parenterally.

The question of amino-acid mixtures for acute liver disorders is then considered, with brief references to the author's experiments (reported at the *Nordwestdeutscher Internistenkongress*, Kiel, July 1953) on rats poisoned with carbon tetrachloride, in which liver regeneration was more rapid on a mixture of all essential amino-acids or on polypeptides than on ordinary diet with sugar, and to clinical results with over 100 patients with acute hepatitis treated with protein hydrolysates (to be reported elsewhere). Among these, 43 out of 53 in coma or incipient coma from virus hepatitis recovered; they had, however, also had choline and vitamin B complex. A summary and tables are also given for N balance experiments by Bonin in the author's clinic (in the press) on 8 patients with hepatitis, severe in 4 of them, and on 2 healthy subjects given Hepa-Tissan, a mixture of amino-acids and invert sugar, or casein, added to a basal diet of protein 70, fat 60 and carbohydrate 150 to 275 g. daily so as to increase N intake by about 6 g. Positive N balances were thereby achieved; with the amino-acid mixture faecal N did not increase and the increase in urinary N was mainly in urea in all but 3. From this it was concluded that amino-acids in limited amounts can be utilised by the deranged liver, and it is suggested that from 15 to 24 g. (2·5 to 3·9 g. N), not more than 1 g. per hr., can be given continuously per 24 hr. by stomach tube. Liver insufficiency with high residual N is a contra-indication.—W. M. Deans.

DAVIDSON, C. S. **Cirrhosis of the liver treated with prolonged sodium restrictions: improvement in nutrition, hepatic function, and portal hypertension.** *J. Amer. Med. Assoc.*, 1955, **159**, 1257–1261. [Thorndike Mem. Lab., Boston City Hosp., Mass.]

Thirty patients, 28 of whom were chronic alcoholics, were given an adequate diet, but Na intake was restricted to 200 mg. daily. In 18 there was diuresis, prompt in 4 cases, delayed in 14, with loss of oedema and ascites. Nutritional state and liver function showed improvement in many, and there was often evidence of reduced portal hypertension. The remaining 12 patients showed no loss of oedema and ascites, but there

was no further ascites formation. All but one of these had an inadequate trial of Na restriction.

SCHNEIDER, R. W. **Problems in the differentiation of the milk-alkali (Burnett's) syndrome and hyperparathyroidism, illustrated by two case reports.** *Cleveland Clin. Quarterly*, 1955, **22,** 184–189. [Dept. Endocrinol.]

Burnett's syndrome is characterised by a high value for Ca in the serum and a low value in urine. Its cause is excessive intake of milk and absorbable alkali. There is no skeletal damage and the dental lamina dura is present. The disease results in renal failure. Primary hyperparathyroidism is characterised by high values for Ca in both serum and urine and is caused by a tumour in the parathyroid tissue. There is skeletal damage and absence of dental lamina dura. The result is again renal failure. Under certain circumstances the diseases may be much alike. Such circumstances are illustrated by 2 abnormal case histories. In one patient, later proved to have Burnett's syndrome, urinary Ca was high; in the other case, of hyperparathyroidism, it was low. The differentiation was made with the intravenous calcium-load test by the technique of Howard *et al.* (Abst. 3250, Vol. 23). When 30 mg. calcium gluconate per kg. bodyweight was given in saline solution over a 4-hr. period, the first patient showed no change in serum P and a reduction in urinary P. The second patient showed a reduction in serum P and an increase in urinary P. This indicated a parathyroid tumour, which was found and removed.

6. FEEDING OF ANIMALS

GENERAL, INCLUDING DIGESTIBILITY TRIALS

2443

Increase of fat and meat after fattening. A mistake in Kellner's "Fütterungslehre", which has been discovered after 48 years. *C. V. Trouw and Co. Bull.*, September 1955, 85–90. Spinozastraat 1, Amsterdam-C.

A study of the change in composition of animals, ox and pig, during fattening has uncovered a peculiar error in Kellner's book "Grundzüge der Fütterungslehre", 11th ed. revised by Prof. Dr. A. Scheunert. The chemical composition is compared of 2 oxen, 4 years old, one half-fat and weighing 558·8 kg. and the other fat, at 643·7 kg., and of 2 pigs from the same litter, one lean at 42·6 kg. and the other fat at 83·9 kg. Calculations based on the oxen showed that of the difference in weight of carcase 94·5 per cent. was fat, 0·6 per cent. nitrogenous substances, water 6·2 per cent. and minerals — 1·3 per cent. For the pigs the differences were, in the same order, 63·4, 8·2, 27·7 and 0·7 per cent. But Kellner sums up the change in composition during fattening roughly in accord with the changes in the pigs.

An appeal to Prof. Scheunert produced the following comment. The data in question come, not from work of Kellner but from the paper of Lawes and Gilbert (*Phil. Trans. Roy. Soc.*, 1859, **2,** 493) and the summing up, which Kellner borrowed with the tables, refers in the original to the pigs only. Kellner's summing up figures for oxen, which agree roughly with those for the Lawes and Gilbert pigs, refer neither to work of his own nor

to the Lawes and Gilbert oxen but to averages of 98 animals analysed by other workers. The mistake which attributes these averages to the Lawes and Gilbert analyses has been repeated without discovery since the first print in 1907.

BLAXTER, K. L. and GRAHAM, N. M. **Plane of nutrition and starch equivalents.** *J. Agric. Sci.*, 1955, **46,** 292–306. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

In energy balance trials with 2 sheep, stable values for losses of energy were obtained after 72 hours' starvation. When feed was again given stable values were not obtained for about 10 days. From the results it could be shown that energy retention depended on intake. A method of describing plane of nutrition which is independent of body size and the quality of the feed is suggested, from which net energy values can be predicted for all planes of nutrition when the value for one plane is known. A simple scheme for feeding livestock taking into account the decline in net energy with rise of plane of nutrition is described. Energy losses in faeces, urine and as heat tended to rise as feed intake increased, and losses in methane fell, and it was not thought possible to estimate net energy from any one of these values.—T. D. Bell.

FRANÇOIS, A. C., LEROY, A. M. and ZELTER, S. Z. Processus digestifs des ruminants. 3. Étude in-vitro de quelques phénomènes de digestibilité associative. [**Digestive processes in the ruminant. 3. Study *in vitro* of phenomena of associative digestibility.**] *Ann. Zootech.*, 1955, **4,** 103–110. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

For part 2 see Abst. 5325, Vol. 24.

By the technique previously described the formation of lactic and volatile fatty acids in the rumen during the digestion of pure starch, cellulose and soluble sugars, green fodder, and lucerne hay alone, or with raw or cooked potatoes, fodder beet or beet molasses was studied. Lactic acid was produced from soluble sugars, beet and molasses, but not from starch, potato or green fodder. The combination of hay and beet or molasses tended to increase the formation of volatile fatty acids at the expense of lactic acid. No lactic acid was produced with hay alone.—T. D. Bell.

SIECK, K. H. Veränderungen der Zellwandbestandteile von Rübenblatt durch die künstliche Trocknung und ihr Einfluss auf Stoffwechselvorgänge bei Schafen (Verdaulichkeit und Energieausnutzung.). [**Changes in cell-wall components of the beet leaf by artificial drying and their effect on metabolic processes in sheep (digestibility and use of energy).**] Extract from *Thesis*, Göttingen, 1955, pp. 4.

Losses in fresh beet leaves by artificial drying were, per cent., dry matter 17·69, organic matter 12·72, crude protein 24·9 and energy 16·4. The digestibility of fresh and artificially dried leaves (Troblako) for sheep was studied. The percentage losses of digestibility after drying were for organic matter 9 to 10, crude fibre 17 to 20, cellulose 13 to 15, pectic acid 4, lignin 30 to 60, and pentosans 0, and the digestible energy fell by 9 to 12 per cent. There appeared to be no relation between digestibility of cell-wall components and that of organic matter. Soaking did not reverse the effect of drying.—D. Duncan.

CHARLET-LERY, G. and LEROY, A. M. Étude comparée de la digestibilité du son de froment par diverses méthodes. [**Comparative study of the digestibility of wheat bran by different methods.**] *Ann. Zootech.*, 1955, **4,** 111–120. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

The percentage digestibility of wheat bran and lucerne hay was estimated in trials with sheep and cattle. The standard method in which the digestibility of the hay was estimated directly and that of bran, in different proportions in the ration, by difference was compared with a method in which allowance was made for the possible variation in digestibility of the hay due to the presence of the bran in the mixed ration. The two methods gave results in good agreement with one another and with values published in the literature.

BALCH, C. C., MURDOCH, J. C. and TURNER, J. **The effect of chopping and lacerating before ensiling on the digestibility of silage by cows and steers.** *J. Brit. Grassland Soc.*, 1955, **10,** 326–329. [Nat. Inst. Res. Dairying, Univ. Reading.]

Silage was made after chopping, lacerating or no treatment of the grass from a timothy and meadow fescue sward. The 3 silages were used in digestibility trials with Shorthorn cows 4·5 to 9 years old and yearling steers. There was greatest loss of N-free extract from the untreated silage, and least from the chopped. The percentage digestibility of all proximate constituents was highest in the chopped silage, followed by the lacerated and then the untreated. Starch equivalents, calculated from the digestible nutrients of the silages, were 50, 47 and 45 in the chopped, lacerated and untreated silages, respectively. Between the digestibility coefficients found with cows and steers there was

good agreement, but for N-free extract they were slightly higher with cows, and higher still for crude fibre. This was thought to be a reflection of the age of the animals rather than the sex.

LONG, T. A., NELSON, A. B. and MACVICAR, R. **Effect of grinding and pelleting upon digestibility of a ration by lambs.** *J. Animal Sci.*, 1955, **14**, 947–950. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

In 3 digestibility trials with 12 wether lambs, grinding of a ration of hay, maize, cottonseed meal and molasses was found to reduce the apparent coefficients of digestibility of organic matter, crude fibre, crude protein and N-free extract, and pelleting of the ground ration was found to increase these digestibility coefficients almost to those of the normal ration before grinding.—J. C. Gill.

DAVIS, R. F., TRIMBERGER, G. W., TURK, K. L. and LOOSLI, J. K. **Feeding value and digestibility of cane molasses nutrients for dairy heifers.** *Cornell Univ. Agric. Exp. Stat. Bull.* No. 914, July 1955, pp. 27.

Results from 2 trials with 104 yearling dairy heifers in all showed that satisfactory growth was maintained when cane molasses replaced maizemeal in the ration on an equal total digestible nutrient basis. In 3 digestibility trials it was found that when much molasses was given the digestibility of the protein in the ration was depressed. When urea and molasses were given together the utilisation of the N.P.N. was less than when urea was given with maizemeal or with maizemeal and molasses. It is concluded that cane molasses is an excellent feed for dairy cattle provided it is given with roughage of good quality and an ample supply of protein.—J. N. Aitken.

2451

DIJKSTRA, N. D. De verteerbaarheid en voederwaarde van guvitine. [**Digestibility and feeding value of Guvitine.**] *Landbouwk. Tijdschr.*, 1955, **67**, 734–736. [Rijkslandbouwproefstat., Hoorn.] English summary.

Guvitine is a by-product of the manufacture of glue and size from guar seed (*Cyamopsis psoralioides* or *C. tetragonolobus*). Preliminary trials showed that cattle would eat 2·5 lb. per head daily for a week. Digestibility trials were made with 3 wethers given 600 g. cubed dried clover and 600 g. Guvitine daily, in 2 portions. The sample used had 14 per cent. moisture and, in per cent. of dry matter, crude protein 55·5, true protein 52·1, crude fibre 8·5, other carbohydrates 30·6 and ash 5·4. Mean coefficients of digestibility were all 80 per cent. or over except N-free extract 79·7 and ash 66·1. Guvitine contains so little fat that it is negligible. The starch equivalent is computed as 68·6 on dry matter or 59 on the material as used. It resembles that of extracted cottonseed cake, which has a similar digestible protein content.

I. Leitch.

2452

CHARLET-LERY, G., LEROY, A. M. and ZELTER, S. Z. Digestibilité chez le porc des constituants d'une farine de luzerne artificiellement déshydratée. [**Digestibility by the pig of the constituents of a lucerne meal artificially dried.**] *Ann. Zootech.*, 1955, **4**, 121–127. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Digestibility trials with 3 pigs from $3\frac{1}{2}$ to $7\frac{1}{2}$ months old, 45 to 150 lb. liveweight, were made with dried lucerne meal as 20 or 35 per cent. of the ration. The lucerne meal had 14·5 per cent. crude fibre and 29·9 per cent. crude protein. At the lower level the percentage digestibility of the crude protein was not affected by the level of lucerne meal in the ration, but all other constituents were slightly improved. The percentage digestibilities at 20 and 35 per cent. levels were: dry matter 78·1 and 66·0; organic matter 77·9 and 66·6; crude protein 69·9 and 70·0; crude fibre 76·1 and 52·7; N-free extract 86·3 and 79·9. The average feeding value of the lucerne meal was 0·79 feed unit per kg., with 20·0 g. protein per 100 g. Towards the end of the trials, at the higher level, some vomiting and reduction of feed intake occurred, which was thought to be due to the saponins in the lucerne meal, but it was not possible to analyse samples for this constituent. It was concluded that dried lucerne meal could safely be included up to 35 per cent. of the ration, provided that the saponin content was not too high.

KRUPKA, J., PLISZCZYŃSKI, Z. and SKULMOWSKI, J. Przydatność i zastosowanie metody wskaźnikowej przy oznaczaniu współczynników strawności dla trzody chlewnej (współczynniki strawności pasty rybiej i mąki grzybowej). [**The suitability of the indicator method for determining digestibility coefficients in pigs. Digestibility coefficients for fish pastes and mushroom meal.**] *Rocz. Nauk rol.* [*B*], 1955, **69**, 195–210. [Inst. Zootech., Dzial Żywienia Zwierząt, Oddział Paszoznawstwa.] Russian and English summaries.

The percentage digestibility of fish paste and mushroom meal was estimated in an experiment with 2 pigs. For fish paste and mushroom meal, respectively, the percentage digestibility of organic matter was 83·39 and 89·61, crude protein 78·68 and 53·91, true protein 99·52 and 66·34, N-free extract 91·74 and fibre 84·99: the last two figures refer to mushroom meal only.

As an indicator Cr_2O_3 was suitable, but SiO_2 was not. The best results were obtained by estimating digestibility of a basal ration with and without the feed under investigation, and calculating digestibility by difference. The small number of pigs used was not sufficient for accurate results. (From summary.)—T. D. Bell.

2454

BOLTON, W. **The digestibility of the carbohydrate complex by birds of different ages.** *J. Agric. Sci.*, 1955, **46**, 420–424. [Poultry Res. Centre, West Mains Rd., Edinburgh 9.]

The digestibility of starting, growing and laying mashes was estimated with chickens 2 to 5 weeks old and 5 to 10 weeks old and pullets in their first laying summer. The digestibility of the carbohydrates was estimated by the conventional method and from the individual constituents. By the conventional method 5 per cent. digestibility was found for fibre, but when allowance was made for the different composition of the substances estimated in the feed and the faeces, it could be shown that sugar and starch were completely digested, but lignin and cellulose not at all. Crude protein and ether extract were each about 87 per cent. digestible. It is shown how the nutritive ratio of a ration can be estimated from analytical data. The adjustments to protein content necessary when fat is added to the ration are described.

KUMANOV, S. Prouchvaniya na lucernovite otsevki kato furazh. [**Waste lucerne seeds as fodder.**] *Nauch. Trudove, Selskostop. Akad. "Georgi Dimitrov," Sofia*, 1953–54, **4/5**, 7–14. Russian summary.

When lucerne seeds are cleaned the waste consists of small and broken lucerne seeds and seeds of dodder and other weeds. The annual output of such waste in Bulgaria is estimated at 250,000 to 300,000 kg. The crude protein content is 30 per cent. on a dry matter basis, nearly equal to that of peas or vetches. The mean values for other constituents, per cent., were fat 8, fibre 16 and minerals 6·43.

With sheep the coefficients of digestibility were crude protein 55, N-free extract 71, fat 82 and fibre 55 per cent. The mixture is thus a valuable protein feed, but it must be thoroughly ground to prevent the spread of dodder. (From summary.)

LARIN, I. V. Kormovye rasteniya senokosov i pastbishch SSSR. [**Fodder plants of the meadows and pastures of the U.S.S.R.**] *Priroda*, 1955, No. 7, 99–103. [Leningrad Agric. Inst.]

Of the rather more than 16,000 species of flower- and spore-bearing plants (not counting the mosses), representing 163 families, in the U.S.S.R., information exists, of one kind or another, regarding the nutrient properties of almost 5000 species, belonging to 135 families. About one-third of the plants studied are characterised only in a general way as "eaten" or "not eaten" by domestic animals. The relation of cattle, sheep, horses, camels and deer to a number of plants has been more or less completely clarified. There is, however, very little information on which wild plants are eaten by pigs, rabbits, birds and wild animals.

Many plants have been found to be not lower in their feed value than Leguminosae and higher than Gramineae. Thus on an "eaten" basis the nutrient value of Algae and Salicaceae was 96 and 94 per cent., respectively, compared with 90 and 92 per cent., respectively, for Gramineae and Leguminosae. The preference of animals for certain plants is said to be a better evaluation of their nutrient value than theoretical evaluations according to their digestibility. Cattle eat either readily or sufficiently well most plants of the following U.S.S.R. families either in pastures or as hay: Gramineae, Leguminosae, Cyperaceae, Salicaceae (leaves), Polygonaceae, Cruciferae, Urticaceae, Caryophyllaceae, Rosaceae and Equisetaceae.

Gramineae occupy the first place and produce 25 per cent. of the yield of pastures and meadows, Compositae the second place. In forest, forest-steppe and steppe zones Gramineae are the principal components of the grassland, in semi-arid regions and deserts Compositae.

PALTRIDGE, T. B. **Studies on sown pastures for South-Eastern Queensland.** *Commonwealth Sci. and Indust. Res. Organiz., Australia, Bull.* No. 274, 1955, pp. 108. [Melbourne.]

Three plant species were studied: *Paspalum scrobiculatum* var. *commersonii*, *Medicago sativa* (lucerne) and *Phaseolus lathyroides*. The nutritive value of *Paspalum* was ascertained from sheep grazing trials. Bodyweight increments were apparently related to the moisture content of the herbage. Starch equivalent and digestible protein content of the grass and lucerne were calculated from chemical analyses. Management of the 3 species to provide grazing throughout the year is discussed.—J. L. Corbett.

2458

MINISTRY OF AGRICULTURE, FISHERIES AND FOOD. **Grassland management.** *Bull.* No. 154, 1955, pp. iv + 67. H.M.S.O., London. Price 3s. net.

The general principles of grassland management are discussed. These include cultivation, fertility and manuring, establishment, the attributes of different types of pasture and the control of

grazing. They are considered in relation to soil and rainfall and to the special needs of the livestock on mixed cattle and sheep farms, general and arable dairy farms, feeding farms and hill-sheep and hill-cattle grazings.—J. L. Corbett.

CHASHKIN, I. and MIRONENKO, M. Molochnaya produktivnost' kobyl Kirgizii. [**The milk production of mares in Kirgizia.**] *Konevodstvo*, 1955, **25**, No. 6, 19–23.

There was no noticeable difference in the composition of milk from mares of the different breeds found in Kirgizia. The Newkirgiz mare's milk was poorer than that of others in fat, but richer in vitamin C, carotene, sugar and protein. The high content of vitamin C and carotene in mare's milk makes it a valuable food. Its vitamin content is considerably higher than that of cow's milk, carotene content only 0·120 to 0·381 and vitamin C content 20 to 23 mg. per litre, whereas in mare's milk the average carotene content was 0·57 to 0·69 and the vitamin C content 97·8 to 135 mg. per litre, the last figures for each being that for the Newkirgiz mare's milk.

According to its chemical composition mare's milk was at its best during the third month of lactation, corresponding to the flush of grass on the high mountain pastures. The vitamin C content of the Newkirgiz mare's milk varied from 123 to 151 mg. per litre and did not depend on the period of lactation, as the highest content was in the third and sixth months (July and October) and the lowest in the first and fourth (May and August). Starting from August the vitamin A content dropped sharply. The best koumiss was produced in July, when it had a content of 8·6 per cent. of volatile acids which determine its flavour.

CATTLE

GROWTH AND FATTENING

2463
KRÜGER, L. and LÜSSE, E. Aufzucht und Mast von Kälbern mit verschieden hohen Gaben Vollmilch. [**Rearing and fattening calves with different amounts of whole milk.**] *Futter u. Fütterung*, 1955, No. 52, pp. 4. [Inst. Tierzucht. Milchwirtsch., Justus Liebig Hochsch., Giessen.]

A number of experiments on the rearing of calves of both sexes are briefly reported, with tables of daily weight gains and quantities of milk used. The numbers of animals in the groups ranged from 2 to over 30.

In the first series there were 2 experiments on the rearing of calves to a slaughter weight of under 100 kg., or to between 120 and 130 kg., without concentrates or hay, *i.e.*, with whole milk replaced at different stages by skimmed milk, either fresh, sour or dried reconstituted, or skimmed milk with 2 per cent. added fat. The best daily gains were in a group changed over during the second week of life to skimmed milk plus 2 kg. whole milk daily. Very good daily gains and carcase quality were obtained also by changing over in the third week of life to skimmed milk with added fat plus 2 kg. whole milk daily. Rearing on whole milk is not economic beyond 90 kg. (South Germany) or at most 120 kg. (North Germany).

In the second series there were 4 experiments, on the rearing of calves to the 13th, 16th, 20th and 26th week of life, with concentrates and hay as well as whole and skimmed milk in varying proportions. The tables include feed costs per kg. weight gain. These experiments are being continued to later stages of growth. Satisfactory gains were obtained with only 51 kg. whole milk

and a milk substitute (dried skimmed milk 45 and finely ground concentrates 55 per cent.) given in liquid form but the cost was high. Costs were remarkably low for one group of bull calves given 121 kg. whole milk and 201 kg. skimmed milk with a concentrate containing 40 per cent. beet slices; daily gains were below normal but the animals were healthy. Concentrates and hay are not recommended for calves to be slaughtered at from 80 to 120 kg., as the meat is only of second quality. In further experiments with heifer calves, gains, but also costs, increased with the amount of whole milk given. It is suggested that 350 kg. whole milk and the same of skimmed milk will suffice to bring heifer calves to a weight of 180 to 200 kg. by 6 months, and preliminary results indicate that giving very little whole milk need not adversely affect lactation performance. In general, much depends on the quality of the milk and of the hay and concentrates given, and avoidance of digestive disturbances is essential.

WHITING, F. and CLARK, R. D. **Raising dairy calves with a limited amount of milk.** *Canad. J. Agric. Sci.*, 1955, **35**, 454–460. [Exp. Farm, Lethbridge, Alta.]

Three comparable groups of 11 Holstein calves each were used. Whole milk was given at the rate of 10 per cent. of bodyweight for 21 days; it was then gradually reduced and finally withdrawn at 30 days. From 4 to 16 weeks of age the calves in group 1 received skimmed milk to a maximum of 15 lb. per head daily. In addition, the calves in this group received a concentrate mixture of oats 68, barley 10, wheat bran 10, linseed meal 10, salt 1 and bonemeal 1 per cent. to a maximum of 5 lb. daily. The calves in groups 2 and 3 received no milk after 30 days of age, but from 1 week of age they were offered a concentrate mixture of oats 32, barley 5, wheat 10, wheat bran 10, linseed oilmeal 10, soya bean meal 17·5, alfalfa meal 5, molasses 8, and minerals 2·5 per cent. The mixture contained added vitamins A and D and riboflavin. Aureomycin and vitamin B_{12} also were given to calves in group 3. After 16 weeks of age all calves received alfalfa hay or pasture and a grain mixture to 1 year of age. Bodyweights, heart girth and height at withers were recorded.

Calves receiving skimmed milk were heavier at 16 weeks than calves in the other groups. The addition of aureomycin had no effect on bodyweight. There was no significant difference between the groups at 1 year of age. It is concluded that heifer calves can be raised successfully from 1 month of age without the use of animal protein.—J. N. Aitken.

ROY, J. H. B., SHILLAM, K. W. G. and PALMER, J. **The outdoor rearing of calves on grass with special reference to growth rate and grazing behaviour.** *J. Dairy Res.*, 1955, **22**, 252–269. [Nat. Inst. Res. Dairying, Univ. Reading.]

Five male Shorthorn calves born in February and March 1953 and 3 groups of 4 born in each of the months February, March and April 1954 were used in 2 experiments. All calves were put out of doors on permanent pasture at birth and received approximately 45 gal. whole milk during the first 8 weeks. Except for a small amount of dried grass offered in the first experiment, pasture grass was the sole diet from 8 to 26 weeks of age. The growth rates of the calves compared favourably with those of calves reared indoors in the normal way. There was no significant effect of month of birth on growth rate. Temperatures as low as 17° F. had little effect on the wellbeing of the calves as judged by the amount of scouring. Although trichostrongyle egg counts of faeces were high in some calves, the growth of the calves was not depressed. It was thought possible that exposure to worm infestation enabled the calves to build up resistance at an earlier age than would be possible under more conventional methods of rearing. The grazing behaviour of the calves is discussed in detail.

PAJĄK, J. and JASIOROWSKI, H. Doświadczenia nad zimnym wychowem cieląt. [**Experiments on cold rearing of calves.**] *Rocz. Nauk rol.* [*B*], 1955, **69**, 211–240. [Zakład Szczegółowej Hodowli Zwierząt SGGW.] Russian and English summaries.

Three groups of 4 Holstein calves were reared (1) in small individual sheds with an outside run, (2) in runs with a shed closed on 3 sides and (3) in a closed cattle barn, the control group. During the experiment the minumum external temperature fell to — 17° C.; in the sheds it fell to — 9° to — 7° while in the cattle barn it was 1° C. All groups received the same feed. During a 6-month period calves in the 2 experimental groups increased their weight 5½ times; those in the control group increased their weight only 3·8 times. Per kg. weight gain the experimental groups consumed about 4·4 oat units (590 g. digestible protein) and the control group 5·6 oat units (707 g. digestible protein). (From summary.)—J. S. Thomson.

PICCHI, G. Accrescimenti ponderali nei vitelli di razza marchigiana e produzione di latte materno. **[Growth in weight of calves of the Marchigiana breed and maternal milk-yield.]** *Zootec. Vet.*, 1955, **10,** 419–426. [Ist. Zootec. Gen., Univ. Camerino.] English, French and German summaries.

The average birthweight of 9 Marchigiana calves, including 2 twin bull calves which were 25 lb. lighter than the others, was 95·5 lb. During suckling for 90 days the average daily liveweight increase was 1·92 lb. The average milk intake was 11·75 lb. daily for the first 2 months, and 7·83 lb. during the last. During the third month a supplement of crushed beans was given.

The growth rate of the calves was not considered satisfactory for such an early maturing breed. The poor performance was blamed on the milk yield of the dams, which did not supply sufficient nutrients for the calves to realise their inherent capacities. Confirmation was obtained in the observation that shortly after supplementation began growth rates increased. In the area under investigation the retarded growth means great loss to the farmer, since most calves are sold at 5 to 6 months old, and would not have time to make up any leeway lost from birth to weaning.—T. D. Bell.

2469

PRITCHARD, G. I., RIDDELL, W. H. and DURRELL, W. B. **The effect of different levels of dietary oxytetracycline on the growth of young dairy calves.** *J. Animal Sci.*, 1955, **14,** 1011–1014. [Dept. Dairy Husb., Vermont Agric. Exp. Stat., Burlington.]

Giving young calves oxytetracycline (terramycin) at daily rates of 15 or 60 mg. per 100 lb. bodyweight did not result in a significant increase in rate of liveweight gain over controls. It was concluded that the lack of response was probably due to the reduction of pathogenic organisms in the station herd as a whole by the continuous use of antibiotics.—J. N. Aitken.

KADIISKI, E. and ZAHARIEV, Z. Sravnitelen opit za ugoyavane na teleta i malacheta. **[Comparative study on fattening calves and buffalo calves.]** *Nauch. Trudove, Selskostop. Akad. "Georgi Dimitrov," Sofia*, 1953–54, **4/5,** 291–311. Russian summary.

The 2 groups each consisted of 4 castrated males and 1 female; the cattle, of local Sofia breed, were 12 to 14½ months old and the buffaloes 13 months, and their mean initial weights were 244·6 and 223·4 kg., respectively. After a short preparatory period they were fattened in stalls from October to January on a ration of meadow hay, succulent fodder and a small quantity of concentrates.

During 113 days of fattening the cattle gained 98·4 kg. and the buffaloes 80 kg., mean daily gains of 871 and 708 g. For each kg. liveweight gain the cattle needed 7·31 fodder units and 629 g. digestible protein and the buffaloes 7·82 units and 748 g. protein.

Their carcase weights were 56·85 and 52·20 per cent. of liveweight. On chemical analysis the carcases contained 10·51 and 18·17 per cent. fat. The bone contents were 18·33 and 18·66 per cent. (From summary.)—D. Duncan.

2472

NELMS, G. and BOGART, R. **Some factors affecting feed utilization in growing beef cattle.** *J. Animal Sci.*, 1955, **14,** 970–978. [Dept. Animal Husb., Oregon State Coll., Corvallis.]

Data from 43 purebred Aberdeen-Angus and Hereford bull and heifer calves were analysed statistically. The within-lines and within-sex effects of birthweight, age at reaching 500 lb. liveweight, and daily gain from 500 to 800 lb. on feed conversion efficiency were determined. Calves which were heavier at birth were more efficient during the period of the test, *i.e.*, 500 to 800 lb. liveweight. During this period bulls decreased in efficiency more rapidly than heifers. Calves which reached 500 lb. at the youngest ages were more efficient than older calves when allowance was made for maintenance. Calves making the highest rate of gain were more efficient than those growing less rapidly.—J. N. Aitken.

2473

SIMONE, M., CARROLL, F., HINREINER, E. and CLEGG, M. T. **Effect of corn, barley, stilbestrol and degree of finish upon quality of beef.** *Food Res.*, 1955, **20,** 521–529. [Dept. Food Technol., Univ. California, Davis.]

The effect on beef quality of steers of finishing them on maize instead of barley, giving a low instead of a high level of concentrates and implanting them with stilboestrol was determined by scoring, for flavour, juiciness and tenderness, samples from representative rib and round roasts. Round roasts from the low-level concentrate group frequently scored less than those from the other groups, but there were no marked differences among the rib roasts from these animals. There

was little variation in any of the measures of eating quality among roasts from steers given barley or maize or implanted with stilboestrol. Eating quality of meat was not highly correlated with its fat content, calculated from sp. gr. measurements.—T. R. Preston.

2474

CHESHMEDZHIEV, B., PETROV, K. and KONSTANTINOV, G. Oborno ugoyavane na volove chrez krovopuskane : opiti s cveklovi ryazanki i spirtovarska kasha. [**Fattening oxen with the aid of bloodletting : studies on fattening with oilcake and brewer's grains.**] *Nauch. Trudove, Selskostop. Akad. "Georgi Dimitrov," Sofia*, 1953–54, **4/5,** 15–30. Russian summary.

On 2 types of diet, one based on oilcake and the other on brewer's grains, roughage and some concentrates, the liveweight gains of cattle were improved when the cattle were bled. In the first experiment the cattle, old working oxen aged from 8 to 12 years, were bled twice with an interval of 45 days, the quantities taken being 1·2 and 2 per cent. of the bodyweight. On equal quantities of feed the bled cattle gained in 3 months on the average 933 g. daily and controls 811 g., and the mean intakes were 10·73 and 12·34 fodder units per kg. liveweight gain. Their carcases weighed 52·81 and 51·94 per cent. of liveweight and the yields of fat were 32·2 and 24 kg. The meat contained 6·7 and 5·4 per cent. of interstitial fat and 72·92 and 73·92 per cent. water. There was no difference in melting-point, refraction or iodine number of the fat.

Similar results were obtained with oxen fattened for 2½ months on the ration based on brewer's grains. Mean daily weight gains were 773 g. for bled and 626 g. for control animals. They killed out at 51·33 and 51·08 per cent. of liveweight, respectively. Bleeding temporarily raised the alkali reserve and lowered serum Ca. Temperature, pulse, respiration and rumination showed no important ill effect. (From summary.)

BURROUGHS, W., CULBERTSON, C. C., CHENG, E. HALE, W. H. and HOMEYER, P. **The influence of oral administration of diethylstilbestrol to beef cattle.** *J. Animal Sci.*, 1955, **14,** 1015–1024. [Iowa Agric. Exp. Stat., Ames.]

The effect of oral administration of stilboestrol, from 2·75 to 20 mg. daily, to yearling steers and heifers was studied in 5 experiments on 120 steers and 24 heifers in all, divided into groups of 8 to 10 animals each. High-grain fattening rations, high-roughage growing rations and rations intermediate in grain and roughage content were used. Rate of liveweight gain and efficiency of feed conversion of both steers and heifers were increased at all levels of stilboestrol, irrespective of the type of ration. Stilboestrol was as effective at the end of the trials as at the beginning. Undesirable side effects were not apparent.—J. N. Aitken.

2477

KLOSTERMAN, E. W., CAHILL, V. R., KUNKLE, L. E. and MOXON, A. L. **The subcutaneous implantation of stilbestrol in fattening bulls and steers.** *J. Animal Sci.*, 1955, **14,** 1050–1058. [Ohio Agric. Exp. Stat., Wooster.]

In dry-lot fattening trials, bulls made more rapid and economical liveweight gains, produced lower grade carcases and yielded more edible meat (boneless meat with a maximum of ⅜ in. fat on any surface) than steers. Implantation of stilboestrol significantly increased liveweight gains of bulls and steers. There was a significant interaction between castration and hormone implantation. Stilboestrol increased the grade and reduced the edible meat yield of bull carcases, but reduced the grade and and increased the edible meat yield of steer carcases. Castration about the middle of the feeding period greatly reduced weight gain and produced carcases similar to those from bulls.

BENNETT, J. A. and MATTHEWS, D. J. **Performance testing studies with beef cattle.** *Utah Agric. Exp. Stat. Bull.* No. 377, June 1955, pp. 15.

The data were obtained from a performance test on 124 Hereford and Shorthorn calves by 6 Hereford and 3 Shorthorn bulls. All animals were fed to appetite from 8 months of age for 168 days. Bodyweights and feed intakes of each animal were recorded. Statistical analysis of the data showed highly significant differences between sire offspring groups in rate of gain and efficiency of feed utilisation. Bull calves made faster weight gains and showed better feed conversion efficiency than heifer calves. Animals which were heavier at the start of the test were also heavier at the end.

A supplementary study with 144 beef steers of Shorthorn, Angus, and Hereford breeding was made to determine the value of body measurements as a basis for estimating dressing percentage. The measurements were height at withers, heart girth, paunch girth and bodyweight. The multiple correlation was highly significant (0·4757) but the coefficient of determination was low, indicating that the 4 body measurements accounted for only 23 per cent. of the variability in dressing percentage. It was concluded that these measurements would not accurately predict dressing percentage or give an indirect measure of percentage fat in the live animal.—J. N. Aitken.

REGENSBURGER, G. Contributo alla valutazione del peso vivo dei bovini in relazione ad alcune dimensioni somatiche. 1. 2. [**Estimation of liveweight of cattle in relation to some body measurements. 1. 2.**] *Ann. Sper. agrar.*, 1955, **9,** 571–603; 825–853. [Ist. Sper. Zootec., Rome.] English summary.

1. Two methods of estimating liveweight of cattle were compared with the true weight found with a scale. The methods were to measure the chest girth, and the distance on one side from the centre of the sternum to the mid-point of the back and thence to the median point between the buttocks, below the hip-bone. This latter measurement is known as Crevat's measurement. When a Crevat's tape is used the linear measurement is automatically converted to the liveweight. Altogether over 1300 Black Pied Dutch cattle from 1 month old upwards and cows in late pregnancy were measured. Crevat's method gave better results than chest girth, but neither method was thought accurate enough for practical use.

2. From the weights and chest girths of 1352 Black Pied Dutch and small numbers of Red Pied Dutch, Brown Swiss and Simmenthal cattle, it was calculated that the relation between chest girth and liveweight could be expressed by the equation $P = 0{\cdot}00055\ T^{2{\cdot}63}$, where P = liveweight in kg. and T = chest girth in cm. In this way liveweight could readily be estimated from a simple measurement with sufficient accuracy for such practical purposes as evaluating feed requirements. The equation refers to animals in a good state of nutrition. In pregnant cows some adjustment would have to be made.—T. D. Bell.

2482

LARKIN, R. M. **Observations on the grazing behaviour of beef cattle in tropical Queensland.** *Queensland J. Agric. Sci.*, 1954, **11,** 115–141. [Cattle Husb. Branch, Div. Animal Indust.]

Grade Shorthorn steers were studied. Pastures varied in quantity and quality but the amount of grazing available was always more than adequate. During hot weather daytime grazing was reduced; the animals spent long periods standing in shade and little time lying down. Though night grazing time was increased in compensation, the net result was a decrease in total grazing time.

DOWLING, D. F. **The thickness of cattle skin.** *Austral. J. Agric. Res.*, 1955, **6,** 776–785. [Div. Animal Health, Sect. Animal Genetics, C.S.I.R.O., Univ. Sydney.]

Skin thickness of European and Zebu cattle was measured. There was a difference between breeds and between sites of sampling. Age did not affect skin thickness, but it was greater in well nourished animals. The skin of the Zebu was thicker than that of the Angus, Shorthorn or Jersey, but not as thick as that of the Friesian, Hereford or Devon, which suggested that thick skin is not essential for heat tolerance. The papillary layer in the Zebu was thinner than in the European breeds and the glands were more densely dispersed. The relationship between skin thickness and heat tolerance is discussed, and the methods of measurement are described.—T. D. Bell.

MACKINTOSH, J. **The feeding of dairy cows.** *Minist. Agric. Fish. Bull.* No. 42, 1955, pp. iv + 46. H.M.S.O., London. Price 2s. 6d. net.

This new edition is on the same plan as the earlier edition but the text has been revised in the light of recent experimental work. Perhaps the most important innovation is the recommendation that the allowance of protein equivalent for milk production should be reduced from 0·6 to 0·5 lb. per gal. Attention is drawn to the changes which have taken place over the past 15 years in the supplies of different feeds available for the winter feeding of dairy herds. Because of the high cost of concentrates there is great need for a higher proportion of the feed for the dairy herd to be grown at home. The place of homegrown feeds, particularly grass and its products, in the rationing of the herd, is outlined. The sections of the bulletin dealing with the role of the main feed constituents, the composition of feeds, feeding standards, selection of rations, palatability, winter and summer feeding and costs are adequate and simply written. A ration ready reckoner is included in a list of 7 useful tables. This bulletin will form a valuable guide to the dairy farmer.

BALCH, C. C., BALCH, D. A., BARTLETT, S., BARTRUM, M. P., JOHNSON, V. W., ROWLAND, S. J. and TURNER, J. **Studies of the secretion of milk of low fat content by cows on diets low in hay and high in concentrates. 6. The effect on the physical and biochemical processes of the reticulo-rumen.** *J. Dairy Res.*, 1955, **22,** 270–289. [Nat. Inst. Res. Dairying, Univ. Reading.]

For part 5 see Abst. 4315, Vol. 25.

Two Shorthorn cows with fistulae were used in an experiment which lasted 27 weeks. The experiment was divided into 5 periods. The rations given during each period were as follows: weeks 1 to 7, both cows received 16 lb. hay and 20 lb. concentrates; weeks 8 to 13, the hay was reduced to 2 lb. and the concentrates increased to 24 lb.; weeks 14 to 19, as in the previous period with the addition of 5 lb. dried straw pulp (concentrates reduced to 20 lb. in week 15); in weeks 20 to 21 the straw pulp was removed from the diet; in weeks 22 to 27 the ration was gradually changed to 18 lb. hay and 10 lb. concentrates. There was a great reduction in the fat content of the milk with the introduction of the low-roughage diet. The addition of straw pulp brought no recovery. While the fat content was depressed there was an increase in the percentage solids-not-fat. There was a decrease in the volatile acid values and an increase in the iodine value of the milk fat.

From the results of digestibility trials it was shown that there was a great decrease in the digestibility of the fibrous carbohydrate with the exception of the pentosans-not-in-cellulose fraction. From analysis of the digesta leaving the reticulo-rumen it was estimated that 90 per cent. of the digestion of starch and 45 to 60 per cent. of the digestion of fibrous carbohydrate, excluding the pentosans-not-in-cellulose fraction, took place in the reticulo-rumen. The falls in milk fat content were associated with diets which lacked the physical property of fibrousness and contained large amounts of starch, 6·2 to 7·4 lb.

When the low-hay diet was given there was a reduction of 50 per cent. in the blood serum lipid fraction. Recovery was complete when dried straw pulp was added to the ration. As there was no concomitant recovery of milk fat content during this period, it was concluded that the fall in fat content of the milk was not due to the decrease in serum lipid concentration.

The weight of acetic acid in the reticulo-rumen was much reduced when the low-hay diet was given. There was little variation in the weight of propionic acid. It was considered probable that as less acetic acid was available when low-roughage diets were given, less was absorbed through the reticulo-rumen wall, and since acetic acid is known to be a precursor of the saturated fatty acid fraction of milk fat, its deficiency may have been the cause of the low fat percentage.—J. N. Aitken.

LAKKE GOWDA, H. S., KEHAR, N. D. and AYYAR, N. K. **Studies on phytic acid phosphorus metabolism in ruminants. 1. Distribution of phytic-acid phosphorus and total phosphorus in some of the common Indian cattle feeds. 2. Influence of high, low and medium levels of ingestion of phytic-acid phosphorus on calcium, phosphorus and magnesium metabolism.** *Indian J. Med. Res.*, 1955, **43,** 603–608; 609–616. [Indian Vet. Res. Inst., Izatnagar.]

1. In general, total P in the dry matter and the proportion of P present as phytate were greatest in oilcakes and cereal by-products and least in cereal straws. Grasses contained an intermediate amount of total P and phytate P.

In plant material at different stages of growth the total P in the dry matter decreased with advancing maturity and the proportion present as phytate generally increased. Irrigation increased

the total P content in the dry matter and decreased the proportion present as phytate.

2. Buffalo bulls were given rations containing different amounts of total and phytate P and the degree of hydrolysis of phytate in the digestive tract and balances of P, Ca and Mg were estimated for each ration.

The degree of hydrolysis of phytate varied among rations from 83 to 41 per cent. A high degree of hydrolysis was associated with a large intake of total and phytate P of which only a small proportion was provided in paddy straw, and a small degree of hydrolysis was associated with a small intake of total and phytate P of which a relatively large proportion was provided in paddy straw.

The P balance was positive on all rations. The amount retained was closely correlated with total and phytate P intake, and loosely correlated with the degree of phytate hydrolysis. Ca and Mg balances were negative in animals on the ration containing a large amount of total and phytate P and positive in animals on the ration containing smaller amounts of total and phytate P.—R. Hill.

KRÜGER, L., MÜLLER, W., GINKEL, E. and SCHULZE, G. Über Futteraufnahme und Verzehrleistungen bei Milchkühen. 2. Untersuchung spezieller Einflüsse auf die Grösse des Futterverzehrs. [**Feed intake and consumption in milk cows. 2. Special influences on the magnitude of feed consumption.**] *Züchtungskunde*, 1955, **27**, 143–153. [Inst. Tierzucht, Justus Liebig Hochsch., Univ. Giessen.]

For part 1 see Abst. 1201, Vol. 26.

Ten cows soon after calving were offered rations which supplied their calculated nutrient requirements for maintenance and milk yield plus enough for another 10 kg. milk daily. The mean intake of the cows ranged from 17·0 to 19·1 kg. dry matter. Eight days after calving the difference between calculated requirement and intake, in terms of production value, was — 1·0 kg. milk, but after 40 days it was + 3·7, after 65 days + 4·9, after 99 days + 5·6 and after 111 days + 10·5 kg. milk. The bodyweight of the cows fell in the time between calving and the peak of lactation and then rose again. Reserves must have been depleted in early stages of lactation. It is concluded that intake was limited not by physiological requirements, but by mechanical conditions.

A series of studies on feed preferences showed that by attention to individual preference and to palatability as affected by stage of growth of the crops and their contamination by weeds, cows can be made to take the greatest proportion of their feed as homegrown bulk feeds and so save expensive concentrates.

The effects of the crude fibre content of the ration were studied in 7 cows giving 10 to 15 kg. milk daily. The best results were obtained with a crude fibre content of 18 to 18·5 per cent.; above this, milk yield fell. The dry matter intake did not fall until the crude fibre content was raised to 28 per cent., but then it fell sharply; the crude fibre intake did not exceed 4·2 kg. daily.

The cows which ate most quickly had with few exceptions the highest intakes. "Fodder volume" for intake and "fodder volume per minute" for rate of eating are more useful criteria than dry matter.—D. Duncan.

PRESTHEGGE, K. Forhold som virker inn på fettinnholdet i mjølk—og vurdering av mjølkefettet som grunnlag for korreksjon av avdråtten. [**Circumstances that affect the fat content of milk and the value of milk fat as a basis for correcting milk yield.**] *Tidsskr. norske Landbruk*, 1955, **62**, 293–307.

Statistical and experimental studies of the relations of fat, protein and lactose in cow's milk are briefly reviewed with reference chiefly to Scandinavian work. Data from milk recording, on the effects of management and of feeding, including the effect of fibre and of specific feeds, *e.g.*, fish oil, are discussed. Formulae for correction to a uniform basis, which in practice is a uniform energy value, are compared, and finally differential prices for milk based on fat content are discussed in relation to the modern movement from butter production to consumption as milk and cream. Everything considered, the energy basis is as fair as any and 4 per cent. milk a useful criterion both for payment and for selection in breeding, where it safeguards against undue emphasis on fat with relative sacrifice of other components, especially protein, which is now valued much more highly than it was.

DAVYDOV, S. G., LEBEDEV, M. M. and BARANOVA, D. I. Povyshenie zhirnomolochnosti ostfrizskogo skota putem mezhporodnogo skreshchivaniya i napravlennogo vospitaniya. [**Improvement of the fat content of milk of East Friesian cattle by crossbreeding and controlled rearing.**] *Izv. Akad. Nauk SSSR Ser. Biol.*, 1955, No. 4, 84–94. [Pushkin Sci. Res. Lab. Agric. Animal Propagation.]

Three groups of crossbred calves were fed on milk of different fat content. Group 1 had milk with a fat content of 3·2 to 3·3 per cent. (normal fat content), group 2 with about 5 per cent. (fat content increased artificially) and group 3 with 2

to 2·5 per cent. (fat content decreased by separation). All groups received the same amount of hay and succulent fodder. The control and high-fat groups were also given 152 to 156 kg. concentrates each during the first 6 months, with a high content of soya cake, oatmeal and bran.

Group 2 developed better than the other 2 groups in both general build and liveweight. They developed into cows producing milk with greater fat content than that of their dams, and although the fat content in this group varied between 3·33 and 3·97 per cent. and in the control group between 2·86 and 3·75 per cent., there was a greater number of cows in group 2 producing milk with a high fat content than in the control group. In the low-fat group there was less variation in the fat content of the milk, all the cows producing milk with a fat content of 3 to 3·2 per cent. Experiments with crossbred and purebred calves showed that crossbreds reacted more strongly to changes in feeding than did the purebreds. It was also found that reducing either the quantity or the quality of the feed given to young animals inevitably led to reduction of the fat content of milk later produced by these animals.—H. Scherbatoff.

PERRIN, D. R. **Milk composition studies in the hormonal induction of lactation using identical twin dairy cattle.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37**, 88–92. [Ruakura Animal Res. Stat., Hamilton.]

Lactation was induced in 1 member of each of 4 pairs of identical twin heifers by treatment over 120 days with diethylstilboestrol and progesterone in the ratio 1000 : 1. The remaining 4 heifers were brought into lactation in the normal way. The initial secretions of the treated animals were similar in composition to colostrum. The milk of treated animals had higher percentages of protein and fat. There was little difference in the contents of lactose, ash, chloride, Ca and P. Total yields were less than half those of the control twins.

HARING, F. and KUBLITZ, M. Beifutter für Milchkühe auf der Weide. Kakaoschalen, Sauerkartoffeln und vielseitiges Kraftfuttergemisch. [**Supplements for milk cows on pasture. Cocoa shells, potato silage and balanced concentrate mixture.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 211–223. [Inst. Tierzucht, Univ. Göttingen.]

Means of counteracting the unexplained fall of fat percentage in milk when cows are on pasture in northwestern Germany are discussed. Cocoa shells, with a protein to starch ratio of 1 : 9·6 and a crude fibre content of 15 or 16 per cent., form a good supplement to young pasture grass; they are not used for cattle feeding in Germany and 10,000 tons a year are either exported at a very low price to other countries for this purpose or are used in other ways. Varying results with high-carbohydrate feeds have been reported; home-produced potato silage low in ballast, with a protein to starch ratio of 1 : 15·3, was available. A trial was made with 3 groups of 7 Black Pied Lowland cows of the same average age, milk yield and stage of lactation. During a pre-period of 14 days covering transition from stall feeding to pasture, group 1 had, daily, ground oats 250, dried beet slices 500 and unextracted cocoa shells (composition given) 145 to 1000 g., group 2 oats and slices as above, with up to 2·5 kg. potato silage, and the control group had then and throughout the experiment only oat and wheat straw as supplements to pasture. For the next 14 days groups 1 and 2 got oats and slices as before and 1·5 kg. cocoa shells or 3 to 3·75 kg. potato silage. For 28 days after that, group 1 was offered 1·75 to 2·175 kg. cocoa shells and group 2 had ground oats 0·35 to 0·7 kg., slices 1·0 to 2·0 kg., and potato silage 2·5 kg. gradually replaced by up to 0·3 kg. of a concentrate mixture of the following percentage composition: a 1 : 1 mixture of cod-meal and fishmeal 41, meatmeal 23·5, soya meal 12·0, cod liver and liver oil 10·0, ground bone 6·0, dried yeast 5·0, $CaCO_3$ 2·5. Finally, for 16 days group 1 had pasture only and group 2 had the same as in the third period. The pasture (botanical composition given) was well managed permanent grass, grazed at fully hand height, a fresh section being provided daily by electric fencing. Milking was in stall, by machine, to avoid disturbance due to changing over to hand milking.

The cows did not hesitate to eat the potato silage or the concentrate. They took a day or two to get used to the cocoa shells and would not take the full amounts intended, most of them not more than 1·1 kg. daily. As usual, the fat percentage of the milk rose in all 3 groups during the first week on pasture, but the rise in group 1, from 3·8 to 4·8, was over twice those in the other groups and, unlike them, was maintained until the cocoa shells were stopped. Potato silage by itself had no effect; the concentrate gave a slight improvement. On the other hand, on cocoa shells the milk yield fell, at first steeply and then more gradually. Potato silage again had no effect and the concentrate gave a slight improvement. The total amount of milk fat produced was much the same for all 3 groups. The cows on cocoa shells gained weight more rapidly at the outset than the controls, probably owing to the constipating effect of the cocoa shells. No ill effect resulted from any of the supplements. From the narrow point of view of returns from milk sales, the supplements were not economic.—W. M. Deans.

2493

DICKEY, H. C. **Dried potato pulp for dairy cattle.** *Maine Agric. Exp. Stat. Bull.* No. 539, May 1955, pp. 7.

The dried potato pulp had the following percentage composition: water 12·29, protein 8·44, fat 0·40, fibre 5·30, N-free extract 69·4 and minerals 4·17. The results from a double reversal trial with 4 pairs of milking cows showed that its value for milk production was equal to that of yellow hominy feed. It is concluded that when given with good hay and silage to make up the vitamin deficiency, and in mixtures containing enough fat, the pulp is a satisfactory concentrate for dairy cows.—J. N. Aitken.

MAINARDI, B. and DORDONI, G. Le variazioni della produzione lattea in rapporto all'età nelle bovine pezzate nere del cremonese. [**Variations in milk production with age in Friesian cattle in Cremona.**] *Riv. Zootec.*, 1955, **28,** 267–271.

The records of 310 Friesian cows showed that the greatest yield was in the fifth lactation. The difference between lactations was not so great as in the Brown Swiss, which is the other breed most used in the province of Cremona. The yield of the Friesians was higher than that of the Brown Swiss, but they did not remain good milkers for as long.—T. D. Bell.

2498

AGARWALA, O. P. and SUNDARESAN, D. **Influence of frequency of milking on milk production.** *Indian J. Dairy Sci.*, 1955, **8,** 94–99. [Dept. Animal Husb., Agric. Inst., Allahabad, U.P.]

This study was made over a 100-day experimental period with 6 cows. One half of the udder of each cow was milked 3 times a day and the other half twice a day for 25 days, and the treatments were reversed during the next 25 days. This procedure was repeated twice during the trial. It was concluded that the production of cows giving on the average 14 lb. milk daily could be increased by 8·4 per cent. by milking 3 times daily.

VAN DER KLEY, F. K. and VAN DER PLOEG, H. Graasgewoonten en voedselopname van Nederlandse rundertweelingen. 1. De graasgewoonten. [**Grazing habits and amount eaten by Netherlands monozygous twin cows. 1. Grazing habits.**]

VAN DER KLEY, F. K. 2. Voedselverbruik en beweidingssysteem. [**2. Grass consumption in relation to grazing management.**] *Landbouwk. Tijdschr.*, 1955, **67,** 609–619; 620–627. [Afd. Graslandcult., Landbouwhogesch.] English summary.

1. The study was made on 4 pairs of identical twin cows with records at 5-min. intervals for 2 days at intervals throughout the grazing season. Roughly 500 min. daily were spent grazing and the same time ruminating. When the day was so short that enough feed was not eaten, the cows grazed about midnight. Two comparable leys, one chiefly of *Dactylis glomerata*, the other of *Lolium perenne*, were grazed at lengths 14 or 11, 17 or 13, 22 or 18 and 40 or 33 cm. Variation within pairs and between pairs was greater than expected. On the average there was little difference between the leys, and 1 kg. dry matter (D.M.) required 20 min. grazing. Total D.M. daily ranged from about 8 to over 23 kg. At low total intakes of D.M. the longer cocksfoot was more quickly eaten than the shorter ryegrass. Optimum length was about 8 in. (21 cm.). Per kg. crude fibre, cocksfoot required 15 min. longer rumination than ryegress.

2. It is calculated that in the grazing of Netherlands pastures 20 per cent. of starch equivalent and 35 per cent. of digestible crude protein is lost. Most of this is loss from overeating; stricter rationing by close folding is recommended. Other losses are due to damage by trampling and by soiling, the latter involving also waste of manure unless it is spread regularly.—I. Leitch.

McDowall, F. H., Patchell, M. R., Hurst, F. and Kelsey, J. M. **Effect of treatment of dairy pastures with BHC and DDT on the flavour and composition of milk, cream, and butter.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37,** 146–155. [Dairy Res. Inst. (N.Z.), Palmerston North.]

Treatment of dry pastures with 2 lb. benzene hexachloride (BHC) containing not less than 99 per cent. γ-isomer (lindane), or with 2 lb. *pp*-DDT per acre did not taint milk, cream or butter provided a period of 3 weeks was allowed to elapse before grazing. Treatment with commercial BHC containing 10 per cent. γ-isomer at 20 lb. per acre caused a slight taint in milk, butter and cream. Treatment of wet pastures with both insecticides and with immediate grazing caused tainting. It was concluded that there was little likelihood of cheese and butter being contaminated with the insecticides provided the pastures were treated when dry and a 3-week interval was allowed before grazing.—J. N. Aitken.

Rigor, T. V. **Dairy cattle feeding problems in the Philippines.** *Philippine J. Animal Indust.*, 1954, **15,** 81–86. [Bur. Animal Indust., Manila.]

The supply of feed for dairy cattle in the Philippines is inadequate and irregular; sometimes the cows have to be kept on pasture alone, and sometimes on concentrates. It is shown that milk production drops towards the end of the rainy season, and rises again only at the beginning of the next rainy season. Improved pasture and forage production are necessary, and schemes with this end in view have been started. The milk yield of imported breeds cannot be expected to be high when feeding is inadequate and climate unsuitable. The protein requirement of dairy cows is discussed in relation to the short supply of protein feeds.

Bettini, T. M. Come alleviare gli effetti del caldo sui bovini nel mezzogiorno. [**How to alleviate the effects of mid-day heat on cattle.**] *Riv. Zootec.*, 1955, **28,** 252–254.

Heat regulation in animals and the effect of temperature and humidity are discussed. The effect of climatic stress on bodyweight, feed and water intake and milk production are described. Practical methods tried in Sardinia consisted in protecting the existing shelters from solar radiation by a second roof which shaded the sides and top and reduced the light inside, and providing electric fans to increase air movement. Clipping the animals also helped.—T. D. Bell.

Repp, W. W., Hale, W. H. and Burroughs, W. **The value of several non-protein-nitrogen compounds as protein substitutes in lamb fattening rations.** *J. Animal Sci.*, 1955, **14,** 901–908. [Iowa Agric. Exp. Stat., Ames.]

In 3 feeding trials with 253 lambs as much as 50 per cent. of the protein N of the ration was replaced by non-protein nitrogen compounds. Urea, ammonium acetate, ammonium propionate, ammonium formate and propionamide proved about equal in feeding value and formamide inferior to all. In one trial with 50 per cent. N replaced, lambs given these compounds made lower weight gains than those on conventional protein, but with 15 and 30 per cent. N replaced lambs given propionamide and urea made gains equal to those on conventional protein. From 2 to 3 weeks were required for lambs to adapt themselves fully to the compounds used, and this was in agreement with studies *in vitro* in which more ammonia N was released from rumen micro-organisms from

lambs previously receiving propionamide than from those from lambs not so fed.—J. C. Gill.

2507

MEISKE, J. C., VAN ARSDELL, W. J., LUECKE, R. W. and HOEFER, J. A. **The utilization of urea and biuret as sources of nitrogen for growing-fattening lambs.** *J. Animal Sci.*, 1955, **14,** 941–946. [Dept. Animal Husb., Michigan State Coll., East Lansing.]

To a basal ration with only 7 per cent. crude protein, a supplement of urea, biuret, crude biuret containing 41 per cent. biuret and 46 per cent. urea, or soya bean oilmeal was added to raise the crude protein level to 9 per cent. The rations were given to 5 groups of lambs, average liveweight 75 lb., for 73 days. All supplements significantly improved rate of gain and efficiency of feed conversion. There was no significant difference between supplements. Carcase grades in all groups were similar.

When 2 lambs were given a drench of urea weekly, signs of toxicity appeared when the level of urea reached 25 g. per 100 lb. bodyweight. Biuret at the rate of 31 g. per 100 lb. bodyweight did not produce signs of toxicity.—T. D. Bell.

BONELLI, P. Coefficienti di normalizzazione della produzione lattea nella pecora sarda. [**Coefficients for standard milk production in the Sarda sheep.**] *Riv. Zootec.*, 1955, **28,** 293–296. [Ispettorato Provinciale Agric., Cagliari.]

The records of 2400 lactations of 300 ewes in the Sarda flock book were examined. It was shown that significantly greater milk yields were obtained from ewes which dropped their first lamb between 12 and 15 months of age than from those lambing for the first time at 2 years of age. It was also shown that the age in years of the ewe was a greater cause of variation in yield than the number of the lactation. The greatest yield was obtained at 5 years of age. From 3 to 7 years there was no significant difference between yields, but ewes younger than 3 and older than 7 gave significantly smaller yields. Coefficients for correcting milk yield for age in order to compare performances are given : 1·867, 1·310 and 1·135 for ewes 1, 2 and 8 or more years old, respectively. The coefficients are higher than have been found for other breeds reported in the literature. At present Sarda sheep are kept in a wild or semi-wild state, and when management has been improved some revision of the coefficients will be necessary.—T. D. Bell.

2511

COOP, I. E. and CLARK, V. R. **The influence of method of rearing as hoggets on the lifetime productivity of sheep.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37,** 214–228. [Canterbury Agric. Coll., Lincoln.]

In a trial with 112 ewes half were reared on a high plane from birth to one year and half on a low plane. At one year of age the average liveweight difference was 30 lb. ; the ewes were then run together. In a second trial with 116 ewes differential feeding extended from 4 to 18 months of age, at the end of which the average liveweight difference was 37 lb. and the ewes were again run as one flock. The effects of these treatments on lifetime performance as ewes were studied.

Though the hoggets reared on the high plane produced an extra 2 lb. wool during the rearing period they were not superior to the ewes reared on the low plane in subsequent wool production. There was no difference between groups in milk production. High plane rearing resulted in about 1 per cent. less ewe mortality, 2 to 3 per cent. fewer barren ewes, 2 to 3 per cent. more lambs and an increase in the productive life of the ewe of 3 to 6 months as measured by the rate of attrition of incisor teeth.—J. C. Gill.

2512

MARTEM'YANOV, B. A. Gustota shersti polutonkorunnykh pomesnykh yagnyat v zavisimosti ot urovnya ikh kormleniya v podsosnyi period. [**The thickness of the wool of semi-fine-wooled crossbred lambs in relation to the level of feeding during suckling.**] *Izvest. Timiryaz. Sel'skokhoz. Akad.*, 1954, No. 3, 119–128.

Of the 2 groups of 10 lambs each under experiment, the first was kept in the flock under ordinary conditions. When penned, each ewe belonging to this group received a daily ration of 2 kg. hay and 1 to 1·5 kg. grass silage ; the lambs were not given any extra feed except hay. The second group was fed more intensively. The average daily ration for each ewe of the second group was, when penned, 2·5 kg. hay, 1·5 kg. silage and 350 to 400 g. concentrates. The lambs in this group were given concentrates and succulent fodder. Towards the end of the experimental period each lamb in the second group was receiving on the average 300 to 500 g. concentrates daily, consisting of oatmeal, bran, linseed and sunflower cakes, also succulent fodder in the form of beet, potatoes and silage, on the average up to 1 kg. of each daily. During the whole experimental period the lambs in this group received on the average as supplements 24·6 feed units and 2559·3 g. digestible protein, and the ewes 35·1 feed units and 6389 g. digestible protein.

The higher level of feeding had a considerable effect in increasing the breadth and length of the lambs, but had less effect on their height. Their liveweight was increased and the improvement in the build of their bodies was accompanied by corresponding changes in the structure of their skin and distribution of the hairs [? wool]. The lambs' skin was 688 μ. thicker in the second group than in the first, this being 34·3 per cent. in favour of the lambs of the first group. The total number of " hairs " per sq. mm. was not affected by the extra feed, but the " down hairs " increased considerably in lambs up to 4 months old, particularly in the lambs of the second group on intensified feeding. At 120 days the lambs of the second group were more mature than the lambs of the first.—H. Scherbatoff.

2513

EL-SHEIKH, A. S., HULET, C. V., POPE, A. L. and CASIDA, L. E. **The effect of level of feeding on the reproductive capacity of the ewe.** *J. Animal Sci.*, 1955, **14,** 919–929. [Dept. Genetics, Univ. Wisconsin, Madison.]

Reproductive capacity of a group of 40 ewes fed on roughage and grain was compared with that of a group fed on roughage only. Half of each group were slaughtered 3 days *post coitum* and the other half at 40 days *post coitum*. Ovulation rate, number of follicles 2 mm. or over in diameter and fertilisation rate were higher and follicles were larger in the group having grain, but embryo survival rate was lower. Uteri were significantly larger at 3 days *post coitum* and horns significantly heavier at 40 days *post coitum*. At 40 days, embryo length and weight, amnion weight, amniotic fluid weight, chorionic fluid weight and size of amnionic vesicle did not differ between the groups, but chorion weight was significantly higher in the group having grain. Embryo and embryonic membranes and fluid weights were greater for singles than for twins. At least 12 per cent. of the embryos migrated from one uterine horn to the other.—J. C. Gill.

2514

NEDKVITNE, J. J. Luta halm er godt sauefôr. **[Alkali-treated straw is good feed for ewes.]** *Sau og Geit*, 1955, No. 5, 93–94.

Sheep readily eat pre-digested straw, and since it has excess alkali, it may suitably be given with A.I.V. silage. For breeding ewes the following rations are suggested: during the " flushing " season, hay 0·5, silage 1·0 and straw 2·0 kg., herring meal 75 g. and barley- and oatmeal 75 g. The hay and cereal are omitted for the next 7 weeks and the straw is raised to 3·5 kg. ; for the last 7 weeks hay is restored, straw reduced to 2·5 kg. and herring meal gradually increased to 100 g. During lactation the ration should be hay 1·0, silage 2·0 and straw 3·0 to 4·0 kg., herring meal and cereal increasing from 100 to 200 g. daily. Straw may be given to lambs also, with hay, silage and herring meal, in amounts up to 2·5 kg. daily.
I. Leitch.

HALE, W. H., HOMEYER, P. G., CULBERTSON, C. C. and BURROUGHS, W. **Response of lambs fed varied levels of diethylstilbestrol.** *J. Animal Sci.*, 1955, **14,** 909–918. [Iowa Agric. Exp. Stat., Ames.]

Wether lambs given about 2 mg. diethylstilboestrol per head daily by mouth gained 22 per cent. more weight than controls similarly fed, and their carcases did not differ in quality. Quality appeared to be impaired when larger amounts were given. When 3·6 mg. diethylstilboestrol was given per head daily in trials with groups of 20 wethers each, rates of gain were not so high as at the lower levels. Severe signs of toxicity seen in stilboestrol-implanted lambs did not appear in any of the lambs, but enlargement of the prepuce, mammary development and oedema of the anal area were noted to a degree associated with the level of stilboestrol.
J. C. Gill.

2517

JORDAN, P. S., JORDAN, R. M. and CROOM, H. G. **Effect of stilbestrol, progesterone-estradiol implants and oral administration of stilbestrol on fattening lambs.** *J. Animal Sci.*, 1955, **14,** 936–940. [Minnesota Agric. Exp. Stat., St. Paul.]

In trials with 110 fattening lambs, implantation of 12 mg. stilboestrol significantly increased rate of liveweight gain but reduced carcase grade and yield. Lambs implanted with 250 mg. progesterone and 10 mg. oestradiol gained significantly faster than controls and their carcases were equal in grade and yield to those of the control lambs. Stilboestrol given by mouth to lambs at levels of 0·1, 0·5 and 1·5 mg. per lamb daily did not increase rate of gain. Carcases of lambs given 0·1 or 0·5 mg. were of a higher grade than the controls and those of lambs given 1·5 mg. were equal in grade to the controls.—J. C. Gill.

PIGS

2520

VERA CRUZ, N. **Raising pigs artificially at Alabang Stock Farm.** *Philippine J. Animal Indust.*, 1954, **15,** 31–38. [Bur. Animal Indust., Manila.]

A litter of 9 pigs was reared for the first 5 weeks on a synthetic milk replacement, Terralac, after suckling for 2 days; a control litter was suckled. Both were reared to 8 weeks of age, and were given access to a starter meal after the first week.

At weaning there was no difference in liveweight between the groups. No pig in the experimental litter died, but in the control litter one died after 1 week and one after 2 weeks. The artificial rearing was successful, but very much more costly than natural rearing. The sow from which the experimental litter was removed dried up within a few days, and was ready for mating 19 days after farrowing.—T. D. Bell.

LEWIS, C. J., CATRON, D. V., COMBS, G. E. (Jr.), ASHTON, G. C. and CULBERTSON, C. C. **Sugar in pig starters.** *J. Animal Sci.*, 1955, **14,** 1103–1115. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

In a series of experiments with pigs weaned at an early age, starter mixtures containing sugar or oat groats were offered free choice. Of mixtures with sugar a preference was shown for that with 20 per cent.; the percentage of oat groats did not affect choice. When meal, crumbles and pellets were compared the preference was for crumbles, closely followed by pellets; very little meal was eaten. Pigs preferred pellets in which the sugar was combined to those which had a sugar coating. Sugar incorporated in pellets or meal significantly improved efficiency, and pelleting also improved efficiency: in combination the effect was additive. The rate of gain and consumption of starter were improved by sugar. This effect was greatest during the first 5 weeks of life.—T. D. Bell.

2523

NOTZOLD, R. A., BECKER, D. E., TERRILL, S. W. JENSEN, A. H. **Saccharin and dried cane molasses in swine rations.** *J. Animal Sci.*, 1955, **14,** 1068–1072. [Illinois Agric. Exp. Stat., Urbana.]

The addition of saccharin to a practical ration for weanling pigs at the rate of 0·03 or 0·1 per cent. had no effect on feed consumption, growth rate or efficiency of feed conversion. Dried cane molasses at the rate of 7·2 per cent. likewise failed to affect either growth or feed efficiency but coul

be used as a source of energy without harmful effect. In a free choice trial of palatability lasting for 55 days pigs showed a preference during the first half of the experiment for maize treated with 0·05 per cent. saccharin over untreated maize or a supplementary feed.—J. S. Thomson.

2524

BECKER, D. E., JENSEN, A. H., TERRILL, S. W. and NORTON, H. W. **The methionine-cystine need of the young pig.** *J. Animal Sci.*, 1955, **14,** 1086–1094. [Illinois Agric. Exp. Stat., Urbana.]

Weanling pigs fed on a synthetic diet containing soya bean protein 12·6, methionine 0·15 and cystine 0·17 per cent. did not grow satisfactorily. The addition of 0·1 or 0·2 per cent. cystine had no effect. Supplements of 0·1 per cent. methionine produced satisfactory growth, but total levels of 0·45 or 0·55 per cent. inhibited growth. The methionine requirement could be partly satisfied by DL-α-hydroxy-γ-methylmercaptobutyric acid. Antibiotics in the diet improved growth and efficiency of gain but did not influence the methionine-cystine requirement of the pig.—A. Hepburn.

2525

LENKEIT, W., GÜTTE, J. O. and STREUTER-PETERMÖLLER, A. Langfristige Untersuchungen zum äusseren und inneren Stoffwechsel des graviden und laktierenden Schweines. 2. Der Ablauf der N-Bilanz vom Ende der Gravidität bis zum Ende der Laktation bei gleichbleibender Ernährung. [**Prolonged studies of external and internal metabolism of pregnant and lactating sows. 2. Course of N balance from the end of pregnancy to the end of lactation, diet being unaltered.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 228–237. [Inst. Tierphysiol., Univ. Göttingen.]

For part 1 see Abst. 1248, Vol. 26.

Three studies were made on 1 sow, 2 on another and 1 on a third. The sows received the same ration from the end of pregnancy to the end of lactation, except that 2 consecutive studies were made on the first sow before and after a change of ration on the twelfth day of lactation. The litters contained from 5 to 11 pigs and the number of times of suckling daily was proportional to the size of the litter. The rations provided from 305 to 977 g. crude protein daily and N balances were estimated; the conversion factors used were 6·25 for feeds and faeces and 6·37 for milk.

The coefficient of digestibility for each ration varied in the course of a lactation within ± 2 per cent. The N content of the milk fell sharply and then slowly in the first 11 to 15 days of lactation and then rose slowly until the end of lactation. There was little influence of feeding on the protein content of the milk, but the milk yield was greater the higher the protein intake. Urine output was greatest in the early stages.

The N balance was always strongly negative at the beginning of lactation, whatever the protein intake or the milk yield, and it even appeared that the higher the protein intake, the more body protein was broken down. The balance approached equilibrium at about the 30th day of lactation.

It is suggested that the course of the N balance during lactation may be influenced by the ration given during pregnancy.—D. Duncan.

2526

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Effect of adding copper to the diet of suckling pigs on creep meal consumption and liveweight gain.** *Chem. and Indust.*, 1955, No. 48, 1554. [Nat. Inst. Res. Dairying, Univ. Reading.]

Previous work (*Chem. and Indust.*, 1953, 871) had shown that a creep meal containing added $CuSO_4$, 25 g. per 100 lb. meal, was more palatable to suckling pigs than the unsupplemented meal and that they ate it in preference. The present note describes an experiment with litters reared indoors, or outdoors on grass, to test the effect of the supplemented meal on growth and meal consumption. In the indoor litters there was little difference at 8 weeks in either weight gain or meal consumption between the control and the experimental group; this was also found in the outdoor groups, although weight gain was higher and meal consumption about twice as high as in the indoor groups. It is suggested that the level of Cu supplementation was not high enough to induce the pigs to consume more of the supplemented meal.—J. S. Thomson.

2527

BOWLER, R. J., BRAUDE, R., CAMPBELL, R. C., CRADDOCK-TURNBULL, J. N., FIELDSEND, H. F., GRIFFITHS, E. K., LUCAS, I. A. M., MITCHELL, K. G., NICKALLS, N. J. D. and TAYLOR, J. H. **High-copper mineral mixture for fattening pigs.** *Brit. J. Nutrition*, 1955, **9,** 358 – 362. [Riseholme Farm Inst., near Lincoln.]

Coordinated trials at 8 centres are reported. Pigs 10 weeks old were grown and fattened to bacon weight. Control pigs got the meal which was usually given at each centre, and experimental groups were given a mineral supplement supplying 250 p.p.m. Cu. Growth rates for control and experimental pigs were 1·40 and 1·48 lb. daily, a statistically significant difference. Efficiency of feed conversion also was improved by the Cu supplement, but not significantly. There was no difference in carcase quality. The reason for the

effect of the Cu is discussed and the need for further investigation of the composition of the pig meat is suggested.—T. D. Bell.

2528

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Antibiotic and copper supplements for fattening pigs.** *Brit. J. Nutrition*, 1955, **9**, 378–381. [Nat. Inst. Res. Dairying, Univ. Reading.]

Previous work on the beneficial effect on growth of pigs of a mineral supplement high in copper (see Abst. 5864, Vol. 25 ; and preceding Abst.) has been extended to compare this effect with that of antibiotics. Five groups of 6 pigs, 10 to 11 weeks old, were given a control basal ration to which additions were made of a mineral mixture high in copper, Aurofac 2A, a combination of these, or copper sulphate alone in an amount equivalent to that in the mineral mixture. All the supplements were equally effective in increasing the rate of gain significantly. The increased rate of growth in the groups receiving the mineral supplement, Aurofac or both was due to an increase in total feed consumption; there was no significant effect on efficiency of feed utilisation. In the group receiving copper sulphate, feed consumption decreased, with a significant improvement in feed utilisation. The different supplements had no effect on carcase grading.—J. S. Thomson.

2529

CHAPMAN, H. L. (Jr.), KASTELIC, J., ASHTON, G. C. and CATRON, D. V. **A comparison of phosphorus from different sources for growing and finishing swine.** *J. Animal Sci.*, 1955, **14**, 1073–1085. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

Dicalcium phosphate was compared with bonemeal, soft phosphate with colloidal clay or phosphate from plant sources, all at 2 different levels, in an experiment with 144 crossbred pigs grown and fattened to 200 lb. liveweight. All animals received rations similar in protein, total digestible nutrients and crude fibre content : half of them got antibiotic and half did not.

Soft phosphate gave poorer rates of gain and efficiency of feed conversion and lower breaking strength of femurs than dicalcium phosphate or steamed bonemeal. The fluorine and ash contents of the femur were increased but P in the bone ash and blood serum was not altered. P from plant sources was not utilised as well as inorganic P.

T. D. Bell.

2530

SCHNEIDER, W. Bericht über einen Schweinemastversuch mit einem Bierhefepräparat. [**Pig feeding experiment with a preparation of brewer's yeast.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 252–255. [Inst. Tierernährungslehre, Landw. Hochsch. Hohenheim.]

Rate of gain, efficiency of feed use, slaughtering losses and quality of pork did not differ significantly in 3 groups of 5, 5 and 6 pigs of the Swabian-Halle breed fed from about 30 to 100 kg. on barley to appetite with a home-mixed protein concentrate including 3 per cent. Waldhof fodder yeast, or the same concentrate with, instead, 3 per cent. " BW-Hefe ", said to contain brewer's yeast 47 and bran 53 per cent., or a certified commercial protein concentrate containing 3 per cent. dried yeast. From these findings and consideration of costs it was concluded that the main use of " BW-Hefe " in pig feeding is as a source of B vitamins, not of proteins. It was found to contain vitamin B_1 33 and riboflavin 26·4 mg. per kg. dry matter ; the Waldhof fodder yeast had 25·9 and 46·2 mg., respectively.—W. M. Deans.

2531

FÉVRIER, R. and VACHEL, J. P. Valeur alimentaire des levures. 3. Comparaison de trois levures d'origines différentes. [**Food value of yeasts. 3. Comparison of three yeasts of different origin.**] *Ann. Zootech.*, 1955, **4**, 129–131. [Stat. Recherches Élevage, Centre Nat. Recherches Zootech., Jouy-en-Josas.]

For part 2 see Abst. 2974, Vol. 25.

Yeasts grown on beet, cheese whey or apple residues gave similar growth rates and efficiency in pigs for 7 weeks from weaning, when they supplied similar amounts of protein to rations with about 17 per cent. crude protein. There were considerable differences in the vitamin B_1, riboflavin and nicotinic acid contents of the yeasts, but this did not affect the growth of the pigs.

LONGWILL, A. **Fodder beet for pig feeding.** *N.Z. J. Agric.*, 1955, **91**, 245–252.

In each of 2 trials one group of pigs was given 1 gal. skimmed milk and 1 lb. meat- and barley-meal, and one group 1 gal. skimmed milk and 2 lb. meat- and barley-meal daily. All pigs were allowed fodder beet of 20 per cent. dry matter to appetite, and were soon eating about 20 lb. each daily. In the first trial they were fattened from 56 lb. to pork weight of 130 lb. liveweight, and in the second from 110 lb. to bacon weight of 160 lb. In both trials the pigs getting 1 lb. meal grew

slightly faster than those getting 2 lb. meal, and the fodder beet supplied 74 and 73 per cent. of the total digestible nutrients in trials 1 and 2, respectively. For the pigs getting 2 lb. meal the fodder beet supplied 66 and 64 per cent. of the total digestible nutrients.

Preliminary tests showed that a crop of fodder beet and maize intersown was well used by pigs folded on it with electric fences. The value of fodder beet for pigs in New Zealand and the economics are discussed.—T. D. Bell.

KMENT, A. and SEEFELDNER, H. Studien über die Beeinflussung der hormonalen Sterilisation und Mast weiblicher Schweine durch eiweissreiches oder eiweissarmes Futter. [**Effect of protein-rich and protein-poor diet on hormonal sterilisation and fattening of sows.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 193–203. [Physiol. Inst., Tierärztl. Hochsch., Vienna.]

The pigs were 40 female Edelschweine aged 4 to 7 months. Ten were controls and 2 groups of 15 received oestrogen on the seventh day after oestrus, a single intramuscular injection which provided 120 mg. stilboestrol dipropionate and 120 mg. stilboestrol dimethyl ether. The rations contained, respectively, 6, 16 and 3 per cent. protein, but were made up of similar constituents, with potatoes and fodder beet as bulk.

Of the 10 control pigs 6 showed regular oestrus, 2 late oestrus and 2 none. Of those given stilboestrol, 11 on the high and 6 on the low protein intake showed periods of excitement or definite oestrus, though not regularly. Feed intake fell in control pigs during oestrus but not in those given stilboestrol.

There was no significant difference in weight increase between the hormone groups, both of which gained better than controls. The heaviest pigs of the high-protein group, those which weighed initially about 100 kg., made the greatest gains of all.—D. Duncan.

CLAWSON, A. J., SHEFFY, B. E. and REID, J. T. **Some effects of feeding chlortetracycline upon the carcass characteristics and the body composition of swine and a scheme for the resolution of the body composition.** *J. Animal Sci.*, 1955, **14,** 1122–1132. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Weanling pigs receiving a basal ration of ground maize, soya bean oilmeal, meat scraps, ground alfalfa and iodised salt had slightly but not significantly better growth when given aureomycin. Dressing percentage, proportion of wholesale cuts in the whole carcase, chemical composition of the carcase meat and estimated composition of the whole empty body (see below) were unaffected.

Body water of 29 pigs, estimated by the antipyrine dilution method, agreed fairly well with direct analysis. The sp. gr. of the carcase was highly correlated with the water content of the carcase but not so highly with the water content of the whole empty body. From a study of published data on 127 pigs it was found that the water and fat contents of the whole empty bodies were highly correlated ($r = -0{\cdot}98$) and that the fat could thus be accurately predicted from the water content. The composition of the fat-free body was variable, but the protein and ash contents were remarkably constant. It was hence possible to estimate the total composition and energy value of the body from the water content of the whole empty body.—A. Hepburn.

EVANS, R. E. **Nutrition of the bacon pig. 18. The influence of dietary penicillin on the growth rate, efficiency of food conversion and the nitrogen retention of the bacon pig.** *J. Agric. Sci.*, 1955, **46,** 329–361. [Sch. Agric., Univ. Cambridge.]

For part 17 see Abst. 3931, Vol. 24.

Penicillin increased liveweight gain and efficiency of feed conversion in pigs fed on a well balanced basal diet of barleymeal, fine bran, alfalfa meal and minerals supplemented with white-fish meal but the differences were not statistically significant.

Penicillin had no statistically significant effect on group-fed pigs receiving the basal diet supplemented with extracted decorticated groundnut meal but the feed was more eagerly eaten. Individually fed pigs receiving penicillin had mean daily liveweight increases of 0·95 lb. and a feed consumption of 2·97 lb. per lb. gain compared with the control values of 0·88 and 3·21 lb. over the interval 36 to 90 lb. liveweight. Both differences were statistically significant. Over the whole period from 36 to 190 lb. liveweight the control pigs required 5·3 more days and ate 19 lb. more meal, an increase of 3·4 per cent. Similar results were obtained in another experiment with pigs fed on the same diet. Vitamin B_{12} produced no further improvement.

Penicillin supplied to group-fed pigs receiving the basal diet containing extracted soya bean meal to appetite produced better growth than in the controls at first, but later the growth of the controls was better. Penicillin had no significant effect on individually fed pigs.

Five N balance trials with 20 pigs fed on these diets showed that penicillin with a balanced diet had no effect, whether the protein was of animal or vegetable origin, provided the pigs were rationed in accordance with their liveweight and the diets were palatable.

It was concluded that the improvement of growth rate, efficiency of feed conversion and rate of N retention to be expected from the inclusion of penicillin in the diet was too small to be economically worth while.—A. Hepburn.

LUCAS, I. A. M. and CALDER, A. F. C. **The growth of pigs kept to one level of feeding in two environments, and fed diets with and without an antibiotic.** *J. Agric. Sci.*, 1955, **46**, 307–319. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Growth rate, efficiency of feed conversion, carcase composition and dressing percentage of pigs kept in good and bad piggeries were recorded. The piggeries have been described previously (Abst. 5873, Vol. 25). All pigs were kept on the same medium level of feeding; the ration had 16·3 per cent. protein from weaning at 42 lb. liveweight to 100 lb. liveweight, and 14·2 per cent. from 100 to 200 lb. liveweight. Half the pigs in each piggery had a supplement of penicillin. The experiment lasted from December to May. During the first half of the experiment the average temperatures in the good and bad piggeries, respectively, were 51° and 43° F. and during the second half 58° and 54° F. No interaction between antibiotic and type of piggery was found, and results were considered comparing antibiotic with no antibiotic, and good piggery with bad.

During the growing period the bad piggery gave slower and less efficient growth, but the difference was not significant. In the fattening period there was no difference in rate of growth, but in the bad piggery efficiency was significantly better. The pigs from the good piggery were fatter and had a higher dressing percentage. Antibiotics did not give any growth response, or affect carcase measurements, but dressing percentages were significantly higher.—T. D. Bell.

2539

WALLACE, H. D., MCKIGNEY, J. I., PEARSON, A. M. and CUNHA, T. J. **The influence of chlortetracycline on the growth and carcass characteristics of swine fed restricted rations.** *J. Animal Sci.*, 1955, **14**, 1095–1102. [Univ. Florida, Gainesville.]

Three experiments with 7, 3 and 3 groups of 8 pigs of initial liveweight 40 lb., fattened to 190 lb., 2 on pasture and one in dry lot, are reported. Some pigs were given unrestricted feed without antibiotic, the same quantity with antibiotic, unrestricted feed with antibiotic or 60 or 80 per cent. as much as the first group with or without antibiotic. The antiobic was chlortetracycline, as crystalline Aureomycin in the dry lot, and Aurofac 2-A in the pasture experiments.

In dry lot no growth response was obtained with the aureomycin on restricted rations, nor was efficiency affected or any change in dressing percentage or carcase quality produced. On pasture there was some improvement in efficiency when the antibiotic was given and rations were restricted, probably because of increased consumption of forage, but there was no significant difference in the rate of gain. Restriction of feed in dry lot gave somewhat higher dressing percentages. On pasture it reduced dressing percentage but increased the percentage of lean cuts. The dressing percentages reported were calculated from final liveweight and warm carcase weight including leaf fat and head.—T. D. Bell.

HILL, E. G. and LARSON, N. L. **Effect of chlortetracycline supplementation on growth and feed utilization of unsuckled baby pigs obtained by hysterectomy.** *J. Animal Sci.*, 1955, **14**, 1116–1121. [Hormel Inst., Univ. Minnesota, Austin.]

In the first 4 experiments piglets obtained by hysterectomy were started in isolation units, without access to colostrum, on a diet of homogenised milk, egg, vitamin D and minerals. At 5 to 25 days of age they were transferred to cages or pens with concrete floors and fed on modified cow's milk or a commercial creep feed. For the experimental groups the chlortetracycline supplement was given at birth or at 21, 28 or 42 days of age at the rate of 5 or 10 p.p.m. on a dry basis. In 3 of the 4 experiments, all at the 10 p.p.m. level, greater weight gains were made by the pigs receiving chlortetracycline. There was no difference with 5 p.p.m. In 2 of the experiments in which feed consumption was estimated, the supplemented groups showed better feed utilisation.

In the last 8 experiments all the piglets were kept in isolation units till 24 days of age and the experimental groups received chlortetracycline at the rate of 10 p.p.m. to 3 weeks and thereafter 200 p.p.m. till 8 weeks. Pigs receiving the supplement showed better growth and feed utilisation than the controls.

These results conflict with those previously obtained with healthy pigs by Speer *et al.* (Abst. 429, Vol. 21).—J. S. Thomson.

2541

McErlean, B. A. **Effect of feeding an aureomycin supplement ("Aurofac") to runt pigs.** *J. Dept. Agric., Republic of Ireland*, 1953–54, **50**, 23–29. [Vet. Res. Lab., Dublin.]

In 2 experiments runt pigs, weighing about 20 lb. and from 66 to 77 days old, were grown and fattened for 112 days on a ration containing separated milk powder, and supplements of 40·3 and 28·8 g. aureomycin per ton of feed in the first and second experiments, respectively. The average growth rates were 1·47 and 1·62 lb. daily for the 2 experiments, and in control groups getting the same basal ration but no supplement growth rates were 1·18 and 1·46 lb. daily. To reach the same weight as the experimental pigs, control pigs took 26 days longer in the first and 12 days in the second experiment. There was no difference in efficiency of feed utilisation due to the aureomycin.—T. D. Bell.

Février, R. and Vachel, J. P. 6. Influence de l'auréomycine et de la pénicilline sur la digestibilité de la ration. [**6. Effect of aureomycin and penicillin on the digestibility of the ration.**]

Legagneur, E. S. and Michel, M. 7. Action des antibiotiques sur porcelets allaités. [**7. Effect of antibiotics on suckling pigs.**] *Ann. Zootech.*, 1955, **4**, 133–135; 136–138; 139–143; 144–145; 146–149; 150–152; 153–163. [Stat. Recherches Élevage, Centre Nat. Recherches Zootech., Jouy-en-Josas.]

1. Implantation of 1000 I.U. bacitracin in pigs 2 to 6 days old did not affect rate of gain or survival to weaning.

2. Growth rate and efficiency from 50 to 200 lb. liveweight were improved by aureomycin plus vitamin B_{12}, and by procaine penicillin added to a ration containing only vegetable protein. The greatest stimulation was in the aureomycin group, and was slightly more from 100 to 200 lb. liveweight than from 70 to 100 lb. There was no effect on carcase quality or the capacity of the caecum. The antibiotics improved appetite.

3. Blood, bile, liver, kidney and ham of pigs which had been given either penicillin or aureomycin from birth were analysed, and the results showed that only traces of the antibiotics were deposited in the tissues.

4. Only small amounts of the antibiotics taken with the feed a few hours before slaughter were recovered in the contents of digestive tract.

5. Total vitamin B_{12} stored in the liver was greater in the group of pigs getting the vitamin with aureomycin, but penicillin without vitamin B_{12} did not increase the stores of the vitamin in the liver over the levels in control pigs. In the small intestine there was more vitamin B_{12} in control pigs than those getting antibiotics, but in the caecum the position was reversed. The quantities of vitamin B_{12} recovered indicated that it was synthesised in the gut, and synthesis was increased by antibiotics in the feed.

6. The percentage digestibility of the ration was not altered by penicillin or aureomycin supplements which had improved growth rate.

7. Aureomycin and chloramphenicol were given to pigs from birth to weaning by incorporating them in soil for the first month and then giving them with skimmed milk. The antibiotics reduced scouring, particularly of the type which persisted more than 48 hr., reduced mortality and increased weaning weights. There was little difference between the bacterial counts in the faeces of treated and control animals which did not have diarrhoea. When antibiotics had been given and diarrhoea occurred, the only change was a slight increase in clostridia in the faeces. In control animals there was an increase in coliform bacilli and Gram-negative streptococci. Studies *in vitro* showed that the antibiotics inhibited the microbiological deamination of arginine, and this was thought to be the possible reason for the growth response.—T. D. Bell.

Pérez-Cuesta, M. Experiencia de alimentación intensiva para la ceba precoz de cerdos ibéricos de raza colorada. [**Experiments in intensive feeding for rapid fattening of pigs of the red Spanish breed.**] *Consejo super. de Invest. Cient. Dept. Zootec., Córdoba*, 1954, pp. 82. English summary.

A trial with 20 red Spanish pigs fattened from weaning to 220 lb. slaughter weight is reported. The pigs were fed to appetite on a balanced meal. At slaughter carcase data were obtained. There was considerable variation between pigs in rate of gain and efficiency of feed conversion, but it was established that animals of this breed were capable of quick economical gains giving good quality carcases, and by selection an improvement in standard could be achieved which would be of great value to the Spanish pig industry.

TAYLOR, J. M. and HAZEL, L. N. **The growth curve of pigs between 134 and 174 days of age.** *J. Animal Sci.*, 1955, **14,** 1133–1139. [Iowa State Coll., Ames.]

Weights of 255 pigs were recorded at 134, 144, 154, 164 and 174 days of age. The weight for age curves were linear for both fast and slow growing pigs. When weight for age was calculated by different methods, and compared with the actual figures obtained in practice, it was concluded that the most satisfactory formula for adjusting actual weight to weight at 154 days was Adjusted weight =

$$\frac{(\text{Actual weight} + 154)\,(199)}{\text{Actual age} + 45} - 154.$$

If weights at 2 ages are known a growth curve could be drawn which would be just as satisfactory.

2545

COEY, W. E. **The relationship between growth rate and carcass conformation in pigs.** *Agric. Progress*, 1954, **29,** 60–65. [Queen's Univ., Belfast.]

Statistical analysis of the results of growth and fattening trials showed significant relations between rate of gain during different periods of life and carcase quality. Rapid early growth improved carcase quality, and rapid growth during the later stages before slaughter reduced it. The results indicate the importance of the difference between periods when the effect of rate of gain on carcase quality is being assessed. It is suggested that rapid gain in the early stages, from birth to 70 lb. liveweight, is as important in producing lean long carcases as restricted gain of weight in the later stages.—T. D. Bell.

DÖRING, H. Über die Verteilung der Geschlechtskombinationen und die Sterblichkeit bei Schweinewürfen. [**Distribution of sex combinations and mortality in pig litters.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, **65,** 169–186. [Max Planck Inst. Tierzucht, Mariensee, Kr. Neustadt a. Rübenberge.]

Analysis of 7272 litters with 81,050 piglets of the German Improved Landschwein breed in the Hanover district between 1931 and 1948 showed that litters with equal or nearly equal numbers of males and females were much more frequent than would be expected from the laws of chance. This is ascribed to foetal mortality chiefly affecting the sex which happens to preponderate. This being so, the opposite sex, being less heavily selected before birth, should show a greater mortality after birth, and the figures for mortality up to 28 days bore this out. The preponderance of balanced litters was more pronounced during and after the war than before, and it is thought that poor feeding led to more intense selection before birth. The total size of litters was also reduced, on the average by 0·216 of a unit. Mortality after birth of survivors of the sex originally preponderating was less than before the war; further evidence for the selection theory. It is suggested that the differential foetal mortality results from the presence in only limited amount of some substance or substances necessary for life but different for the sexes.—W. M. Deans.

GOATS, RABBITS AND OTHER MAMMALS

2547

FRENCH, C. E., MCEWEN, L. C., MAGRUDER, N. D., INGRAM, R. H. and SWIFT, R. W. **Nutritional requirements of white-tailed deer for growth and antler development.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 600, July 1955, pp. 50.

The difficulties of rearing deer in confinement are discussed. In the 2 experiments reported, extending over 2 years, 26 fawns were reared to 6 months on a diet of milk, green alfalfa hay and a calf starter. Two pens of 2 were then given to appetite rations believed to be complete in all nutrients and other similar pens received the same diet in restricted amounts or rations low in protein, Ca or P. Other pens had the deficient rations supplemented with Ca, P, protein, vitamins A and D, sulphur or methionine. The energy value of the diet was about 4 Cal. per g., the protein content ranged from 4·7 to 16·8 per cent., Ca from 0·07 to 0·74 per cent. and P from 0·25 to 0·68 per cent. Growth data indicated a requirement of about 2 lb. feed (3600 Cal.) for a deer weighing 50 to 60 lb., 3 to 4 lb. (6300 Cal.) for one weighing 100 lb. and 5 to 6 lb.

(9900 Cal.) for one weighing 150 lb. Growth during the first year was best on the complete diet (108 lb. gain); all the other diets seriously affected growth, although the diet containing only 0·09 per cent. Ca gave a weight increase of 80 lb., increased to 99 lb. by a supplement of Ca. Protein requirement for optimum growth was 13 to 16 per cent. of the ration. Approximate Ca and P requirements could not be determined but appeared to be in excess of 0·09 and 0·25 per cent., respectively. The addition of sulphur or methionine to the low-protein rations had no effect on growth, nor had the addition of vitamins A and D to the low-P rations. Best antler growth was obtained with the complete diet, but it was almost as good in those receiving Ca and P supplements.

In the second year of the experiment one of the 2 deer in each of the restricted or supplemented groups was given the complete diet to determine the powers of recovery, the remaining deer being maintained on its original diet. Weight recovery and antler growth in the deer originally restricted in feed intake was good but not so good as in the deer maintained all the time on the complete diet; deer maintained on the low-protein and low-Ca and -P diets were only about half the size of the controls and developed thin spike antlers.

ABRAMOV, M. D. and POVETZKIĬ, I. G. Normy i ratziony dlya plemeanogo i tovarnogo molodnyaka golubykh pestzov. [**Standards and rations for the stock and store young of blue Arctic foxes.**] *Karakul. i Zver.*, 1955, **8,** No. 2, 22–27. [All-Union Sci. Res. Lab. Fur-Bearing Animals.]

Cubs to be kept for stock were given rations with a higher energy value than those to be killed for fur; the proportions of different feeds in the ration were also different.

The energy value of the ration per head for stock cubs ranged from 550 to 700 Cal. daily; for the others it was from 500 to 650 Cal., both according to the season of the year.

As percentages of the energy value the constituents of the ration were: *for stock*, meat and fish 60 to 70, dairy products (summer only) 5 to 10, grain 12 to 28, vegetables 3 to 5, dried yeast 3 to 5 and fish oil 2; *for fur* the corresponding percentages were 50 to 60, 5 to 10, 22 to 33, 3 to 5, 3 to 5 and 2.

These rations were given to the cubs from 2 months old. As the cubs grew up, some might be moved from one group to the other, but this was not found to have any adverse effect either on their reproduction or on the quality of the fur.

O'NEIL, J. B. **Percentage size of chick at hatching and its relationship to growth and mortality.** *Poultry Sci.*, 1955, **34,** 761–764. [Dept. Poultry Husb., Univ. Saskatchewan, Saskatoon.]

2551

BIRD, H. R. **"Performance index" of growing chickens.** *Poultry Sci.*, 1955, **34,** 1163–1164. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

When "performance index" of growing chickens is calculated by considering weight gain and efficiency of feed conversion the gain in fact is used twice in the calculation, thus

$$\text{Performance index} = \text{Gain} \times \frac{\text{Gain}}{\text{Feed}}.$$

This has been criticised on the grounds that weight gain is given too much emphasis. It is considered justifiable when it is understood that the interest of the breeder is in gain per unit of time and in gain per unit of feed. This is discussed, and it is pointed out that other workers have shown that net returns were only slightly more affected by feed per unit gain than by time taken per unit gain.—T. D. Bell.

2552

AUSTRIA, I. V. and MARQUEZ, L. S. **Preliminary report on the observations regarding the use of different chick starter mash.** *Philippine J. Animal Indust.*, 1954, **15,** 25–30. [Bur. Animal Indust., Manila.]

Starter mashes made with rice bran, ground maize and fishmeal, some with copra meal and molasses, were inferior to a commercial meal in growth trials with day-old chicks. The addition of an antibiotic feed supplement to the experimental rations reduced mortality and improved growth and efficiency, but not to the same level as with the commercial starter.—T. D. Bell.

WILLIAMS, R. J. and DEBUSK, B. G. **Overnight nutritional responses of chicks.** *Proc. Nat. Acad. Sci., Washington*, 1955, **41,** 894–899. [Biochem. Inst., Univ. Texas.]

In tests with newly hatched chicks, lasting from 18 hr. to 3 days, deficiencies of 13 amino-acids, fatty acids and trace minerals were detected in synthetic rations as judged by growth rates and feed efficiency. The method is described and the results of experiments are presented. The practical possibilities and the limitations of the method are discussed.—T. D. Bell.

2554

GRAU, C. R. and WILLIAMS, M. A. **Fish meals as amino acid sources in chick rations.** *Poultry Sci.*, 1955, **34,** 810–817. [Dept. Poultry Husb., Univ. California, Davis.]

Tests with over 100 commercial samples of fishmeal showed that 48 per cent. of them gave good growth in chickens, 40 per cent. fair and 12 per cent. poor. The results were not related to the percentage of protein in the fishmeal. Sardine meals had the greatest number of samples promoting good growth rates; with other types results were more variable. Differences in methods of processing were not related to the quality of the meals, as indicated by the growth rates of the chickens, and quality did not depend on whether fish were processed fresh or unfit for canning.

T. D. Bell.

2555

HILL, C. H. and KELLY, J. W. **The effect of fish meal and antibiotics on the growth of chicks fed equal amounts of feed.** *Poultry Sci.*, 1955, **34,** 1030–1032. [Dept. Poultry Sci., N. Carolina State Coll., Raleigh.]

The results of 3 experiments are reported with New Hampshire chickens, raised in clean quarters, on the effect on growth of the addition of fishmeal or antibiotics, 100 mg. per lb., or both to a maize and soya bean basal ration containing adequate amounts of vitamins, minerals and methionine. In each experiment feed intake was equalised in all groups.

Neither of the supplements given individually had any effect on growth, but when both were added there was a significant increase in weight gain at 4 weeks. Reasons for this are suggested.

J. S. Thomson.

2556

HOHLS, H. W. Der Anteil tierischen Eiweisses im Kükenaufzuchtfutter und sein Ersatz durch pflanzliches Eiweiss bei Zugabe von antibiotischen Mitteln. [**The role of animal protein in chick rearing rations and its replacement by plant protein with antibiotics.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 238–249. [Bundesforschungsanst. Kleintierzucht, Celle.]

Studies were made on 84 groups of 19 or 20 growing and fattening chickens. The rations contained 16 to 17 per cent. total protein in the first 4 weeks of life, but often this was later reduced. Supplements of penicillin or more rarely aureomycin or terramycin were given in some experiments, and sometimes vitamin B_{12}.

It was concluded that not more than 5 per cent. of animal protein is necessary for adequate feed utilisation, and that when antibiotics are given the animal protein can be reduced to 2 per cent.

SQUIBB, R. L. and BRAHAM, J. E. **Blood meal as a lysine supplement to all-vegetable protein rations for chicks.** *Poultry Sci.*, 1955, **34,** 1050–1053.

Lysine is one of the chief limiting amino-acids in poultry rations compounded of Guatemalan feeds and bloodmeal was used as a source in all-vegetable-protein rations for chickens. The addition of 3 per cent. bloodmeal or 0·45 per cent. L-lysine to a basal ration of sesame oilmeal and ground maize resulted in significant stimulation of growth but the addition of 4 per cent. ramie meal did not. Further experiments showed that 2 to 4 per cent. bloodmeal was most effective, and that 8 per cent. depressed growth. Desmodium, cottonseed and corozo oilmeals added to the basal ration also stimulated growth.—J. S. Thomson.

2558

PEPPER, W. F. and SLINGER, S. J. **Value of supplementary methionine for turkey diets.** *Poultry Sci.*, 1955, **34,** 957–962. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Eight groups of turkey poults were fed from hatching to 24 weeks on a basal mash containing 28 per cent. crude protein, 0·43 per cent. methionine and 0·42 per cent. cystine. Duplicate groups received a supplement of 0·025 per cent. methionine for the whole period, others received it to 8 weeks but not thereafter, and others from 8 to 24 weeks only. After 8 weeks the birds had mash, wheat and oats to appetite.

At 8 weeks the birds receiving the methionine supplement were significantly heavier than the controls and showed better feed efficiency. Groups receiving the methionine supplement to 8 weeks only or during the whole period were heavier at 24 weeks than those receiving the supplement from 8 to 24 weeks only or not at all, but the differences were not significant. The use of methionine for the first 8 weeks only was as effective as its use during the 24-week period. On

the basis of feed consumed from 8 to 24 weeks and from estimation of the composition of the diet it is concluded that the methionine requirement in the presence of adequate cystine is about 1·48 per cent. of the protein.—J. S. Thomson.

MILNE, F. N. J. **Studies on condensed whale solubles in chick starter rations.** *Queensland J. Agric. Sci.*, 1955, **12,** 21–31. [Poultry Branch, Div. Animal Indust.]

In 2 experiments with chicks reared from 2 to 7 weeks of age condensed whale solubles were used to replace all or part of the meatmeal in the starter mash. In the first experiment the solubles had been stored for 18 months, and in the second for 5 months. In the second, one group of chicks got condensed whale solubles and livermeal.

In both experiments growth was progressively depressed by increasing amounts of solubles in the ration, and dermatosis developed. In the first experiment there was also high mortality and poor feathering in the groups getting the solubles. In experiment 2 the addition of livermeal improved growth rate over that of a group getting all fish-meal, and prevented the dermatosis. Deficiency of biotin in the whale solubles was thought to be responsible for the poor performance of the birds. This is discussed.—T. D. Bell.

SLINGER, S. J., PEPPER, W. F. and HILL, D. C. **The use of keratin products in poultry rations.** *Poultry Sci.*, 1955, **34,** 919–922. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Four keratin products prepared from dried beef hooves, fresh beef hooves, pig hooves and pig hair were found to have no nutritive value for chickens when added to a basal ration of soya bean oilmeal alone or with bloodmeal.—J. S. Thomson.

2562

SLINGER, S. J., MCCONACHIE, J. D. and PEPPER, W. F. **The value of animal fat for different strains and crosses of broilers.** *Poultry Sci.*, 1955, **34,** 789–794. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

One hundred chickens from each of 10 different strains were fed for 10 weeks on a practical broiler ration and a similar number had the same ration except that 5 per cent. tallow and 2 per cent. soya bean oilmeal replaced 7 per cent. wheat. Statistical analysis of weight data showed that the effects of strain, sex and diet were highly significant. The interactions between strain and sex, strain and diet, and sex and diet were not significant, but only 2 of the 10 strains showed no weight response to the fat diet and in all but 2 of the strains the males showed a greater response than the females to the fat diet. Feed efficiency was in all cases improved by the addition of fat.—J. S. Thomson.

LEWIS, R. W., BRAY, D. J. and SANFORD, P. E. **Chicks prefer fat-supplemented diets.** *Poultry Sci.*, 1955, **34,** 1165–1167. [Dept. Poultry Husb., Kansas Agric. Exp. Stat., Manhattan.]

Basal rations for chickens from 1 to 8 weeks old were compared with the same diet with 2 per cent. lard or maize oil added. The birds had free access to each diet. They ate more of the diets supplemented with fat, but the kind of fat made no difference. The birds getting the fat supplements reached greater weights than those getting the basal ration only, but efficiency of feed conversion was not altered.—T. D. Bell.

ARSCOTT, G. H. and COMBS, G. F. **Unidentified growth factors required by chicks and poults. 4. Experimental variables which influence the dietary requirements of chicks for these factors.** *Poultry Sci.*, 1955, **34,** 843–850. [Dept. Poultry Husb., Univ. Maryland, College Park.]

For part 3 see Abst. 5520, Vol. 24.

Experiments are reported on the response of day-old chicks during 4 weeks to sources of unidentified growth factors when the basal ration was modified. The effects of using cerelose or sucrose as the source of carbohydrate, adding 0·03 per cent. iodinated casein, raising the level of vitamins, and of multiple deficiency states were studied.

Greater responses to supplements providing unidentified growth factor were obtained with sucrose as the source of carbohydrate than with cerelose. The addition of 0·03 per cent. iodinated casein increased the response to dried whey or a liver product alone or in combination. The effect of high levels of vitamins was not consistent, but there seemed to be a tendency for this treatment to reduce to some extent the requirement for the factor in condensed fish solubles. From the studies on multiple deficiencies of unidentified growth factors it seemed that condensed fish solubles contained 2, one of them present also in a liver fraction and the other in dried alfalfa meal.—T. D. Bell.

SCHAEFER, A. E., GREENE, R. D., SASSAMAN, H. L. and WIND, S. **Fermentation meals as a source of unidentified chick growth factors.** *Poultry Sci.*, 1955, **34,** 851–855. [Squibb Inst. Med. Res., New Brunswick, N.J.]

Streptomycin mycelium (SM) and penicillin mycelium (PM) residues were tested as sources of unidentified growth factors in trials with chickens grown to 8 or 11 weeks of age. Growth was best stimulated by 3 per cent. PM or SM, or a combination of 1 per cent. PM and 0·5 per cent. SM. The addition of 5 mg. procaine penicillin per kg. feed to any of these supplements did not improve growth further, and the responses obtained were better than those from a supplement of fishmeal and yeast. Procaine penicillin alone, added to the basal ration, improved growth more than did fishmeal and yeast, but not as much as the combination of PM and SM. In further trials a compound of PM and SM at a level of 0·8 per cent. gave better growth than 4 per cent. fishmeal or distiller's solubles, and when the mycelium residues were added to either of these supplements growth was better than without them, though only slightly better than with the PM and SM compound alone.

The water-soluble fraction of an autolysate of SM, estimated to contain 10 per cent. of its solids, was as effective when added as 0·1 per cent. of the ration as was 3 per cent. of the original SM. This suggested that the process of autolysis improved the value of the soluble fraction.—T. D. Bell.

ATKINSON, R. L., FERGUSON, T. M. and COUCH, J. R. **Further studies on unidentified growth factor sources for Broad Breasted Bronze turkey poults.** *Poultry Sci.*, 1955, **34,** 855–861. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

As sources of unidentified growth factors for turkey poults, condensed fish solubles, hydrolysed whey, dried whey and dried brewer's yeast were tested in one trial; condensed fish solubles, dried distiller's solubles and dried brewer's yeast in a second; and lactose-free whey, dried whey, dried brewer's yeast and condensed fish solubles in a third. The basis for comparison was rate of gain from hatching to 8 weeks of age.

In all the trials the dams had been maintained on rations believed to contain sources of all unidentified growth factors. In the first trial the poults were hatched from eggs laid from the 18th to 20th week of production. All supplements and combinations of supplements increased growth; either form of whey with fish solubles was better than either separately, but the combination of dried yeast and fish solubles was no better than fish solubles alone. There seemed to be one factor in the whey and another in the yeast and fish solubles.

The poults in the second experiment were from eggs laid only 6 weeks into the laying period, and no growth response was obtained with any supplement.

Eggs from which the poults in the third trial were hatched were laid in the 15th week of the laying period. Again growth responses were obtained with all the supplements tested, greater when condensed fish solubles, lactose-free whey and dried whey were added as 5, 2·5 and 5 per cent., respectively, than when they were added at only 2·5, 1·0 and 2·5 per cent. With dried yeast 2·5 per cent. was better than 5 per cent. With 2·5 per cent. lactose-free whey growth was better than with the same amount of dried whey and equal to that with 5 per cent. dried whey.

It was considered that the unidentified factor was associated with the protein of the whey. Combinations of the different supplements had the same effect as was found in the first trial. Comparing the 3 trials, it seemed that there was a carry-over of growth factors from the hens, and this emphasised the importance of choosing depleted poults for this type of trial.—T. D. Bell.

MARCH, B., BIELY, J. and TOUCHBURN, S. P. **Studies on an unidentified chick growth factor in dehydrated green feed.** *Poultry Sci.*, 1955, **34,** 968–972. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

Growth data are reported from 2 experiments with cockerels and pullets fed on a purified basal diet complete in all known vitamins to which was added 5 per cent. herringmeal, 3 per cent. dehydrated cereal grass, 3 per cent. dehydrated alfalfa or a combination of herringmeal with each of the green feeds. In the first experiment neither dehydrated green feed alone nor herringmeal alone stimulated growth. When herringmeal and dehydrated cereal grass were given together there was a significant increase in rate of growth. An increase was obtained also with herringmeal and alfalfa, but it was not significant. In the second experiment the cereal grass alone gave a significant increase, but not the alfalfa, and the herringmeal and alfalfa, given together, also showed a significant increase. As in the first experiment, there was a much increased rate of growth with the mixture of herringmeal and cereal grass. It is concluded that herringmeal and dehydrated green feed each contain a separate growth factor for chickens, but that they can act only in the presence of each other.

Three other experiments are reported of a similar nature except that the chickens used were from hens which were fed on experimental diets

with or without dehydrated green feed. The same supplements were used as in the first 2 experiments. From the difference in growth responses of the chicks it is concluded that there is a carry-over of the growth factor present in dehydrated cereal grass from the dam to the chick.—J. S. Thomson.

HOHLS, H. W. Kükenaufzuchtversuche mit Penicillium-Mycel. [**Chick rearing experiments with penicillin mycelium.**] *Arch. Geflügelk.*, 1955, **19,** 425–432. [Bundesforschungsanst. Kleintierzucht, Celle.] English summary.

Four groups of 19 White Leghorn chicks were reared to 8 weeks in dark batteries on a ration of wheat, oat kernels, hulled barley and maize 14 each, lucerne meal 4, wheat germ 2, minerals 3, meatmeal 8·6, soya grits 10·2 and wheatfeed 16·2 per cent., with 500 mg. Dohyfral D 80 per 100 kg. ration, or the same with 4·5, 13·6 or 22·8 per cent. penicillin mycelium (corresponding to 1, 3 or 5 per cent. mycelium protein) replacing some or all of the meatmeal, and compensatory adjustments in the amounts of soya grits and wheatfeed were made.

Final weights were slightly greater with 3 per cent. mycelium protein and slightly less with 5 per cent., probably because the digestibility of the protein of this ration was less than that of the others. From measurements of the respiratory quotient twice weekly (see Abst. 4702, Vol. 24) the biological values of the 4 different protein mixtures were calculated weekly. They differed little and declined in much the same way with the age of the chicks, except for an unexplained rise in the sixth week, possibly due to a change of temperature. The results are discussed in conjunction with those of Wetterau (*Kühn-Archiv*, 1954, **68,** 202), from which they differ. The present experiments do not establish the most economic proportion of penicillin mycelium for the rearing of chicks.—W. M. Deans.

DANNENBURG, W. N., REID, B. L., ROZACKY, E. E. and COUCH, J. R. **An inorganic chick growth response.** *Poultry Sci.*, 1955, **34,** 1023–1026. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

In 2 trials the addition of 3 per cent. dried distiller's solubles or the ash of a similar quantity of the solubles to a synthetic basal ration for chicks was compared. In both trials the response to the ash was about half the response to the original solubles, when growth to 4 weeks of age was the criterion. Additions of trace elements did not alter the difference in response, and 0·5 per cent. added Ca, bringing the total Ca to 1·58 per cent., without the addition of either of the solubles supplements, depressed growth.

In another trial the basal diet with added Ca again depressed growth, but the addition of 3 or 10 per cent. dried distiller's solubles with the Ca increased growth rates more than the solubles supplements alone. The response to 10 per cent. solubles was 5 per cent. greater than that to 3 per cent. solubles. The additional response to 10 per cent. solubles with added Ca was 10 per cent. It was thought that dried distiller's solubles may contain a substance that affects utilisation of Ca by the chick.—T. D. Bell.

WILCOX, R. A., CARLSON, C. W., KOHLMEYER, W. and GASTLER, G. F. **The availability of phosphorus from different sources for poults fed practical-type diets.** *Poultry Sci.*, 1955, **34,** 1017–1023. [Dept. Poultry Husb., S. Dakota Agric. Exp. Stat., College Station.]

Growth rate from day-old to 4 weeks and percentage ash in the tibia were the criteria used in trials comparing 18 different sources of inorganic P for turkeys. As a preliminary, trials were made which showed that the optimum level of total P in the ration was 1·0 per cent. It was calculated that 0·45 per cent. was phytin P from plant sources and therefore 0·55 was inorganic P, a value in agreement with other workers' findings.

For the control group 0·15 per cent. dibasic Ca phosphate was added to the basal ration. Altogether 12 trials were made, and defluorinated rock phosphate, imported rock phosphate, soft phosphate with colloidal clay, monobasic Ca phosphate, bonemeal, dicalcium phosphate, tribasic Ca phosphate, and beta tricalcium phosphate were tested. The utilisation of P from colloidal phosphate, tribasic and tricalcium phosphate and some samples of commercial dicalcium phosphate was unsatisfactory. Other sources tested were suitable for turkeys, the best being monobasic Ca phosphate, steamed bonemeal and some samples of commercial dicalcium phosphate and defluorinated phosphate. The results are presented in detail.—T. D. Bell.

ANDERSON, J. O., HURST, J. S., STRONG, D. C., NIELSEN, H., GREENWOOD, D. A., ROBINSON, W., SHUPE, J. L., BINNS, W., BAGLEY, R. A. and DRAPER, C. I. **Effect of feeding various levels of sodium fluoride to growing turkeys.** *Poultry Sci.*, 1955, **34,** 1147–1153. [Dept. Poultry Husb., Utah State Agric. Coll., Logan.]

Six groups of 12-week-old and 6 of 10-week-old turkeys of both sexes were fed on a basal ration containing 43 p.p.m. F to which sodium fluoride was added in groups 2 to 6 to give levels of 100, 200, 400, 800 and 1600 p.p.m. The experiment

lasted for 16 weeks. Feed consumption was not affected until the level of F reached 400 p.p.m., when there was a slight decrease; the decrease was much greater at the 1600 p.p.m. level. Weight gain by male turkeys was affected at the 200 p.p.m. level, but in females not greatly until the 800 or 1600 p.p.m. level was reached. Among the birds on the 2 highest levels extreme variations in weight gain were found, some of the birds having nearly normal weight and condition. Feed efficiency was not greatly affected at the 100 p.p.m. level, but was much decreased at the higher levels. There was a great increase in F content of the bones as F intake rose. After 16 weeks on the basal ration the F content of the femur was 360 p.p.m. on the dry, fat-free basis; in the group on the 1600 p.p.m. level the value was 14,900 p.p.m. Considerable increases were also found in the F content of the soft tissues.—J. S. Thomson.

FANGAUF, R. Der Einsatz von Mineralstoffen, Vitaminen und Antibiotica in den Mischfuttermitteln für Geflügel. (Referat anlässlich der 3. Tagung über Probleme der Tierfütterung in Europa [FAO/EAAP] in Göttingen am 26./30. September 1955.) [**The addition of minerals, vitamins and antibiotics to mixed feeds for poultry. Report to the 3rd meeting on Problems of Animal Feeding in Europe (FAO : EAAP) at Göttingen, 26-30 September, 1955.**] *Arch. Geflügelk.*, 1955, **19,** 471 – 484. [Kiel - Steenbek.] English summary.

The problems of supplying hens and turkeys with minerals and vitamins and of speeding up growth by means of antibiotics are discussed in the light of conditions in Europe.

In Germany the following standard mineral mixture (*DLG-Mineralstandard* I*a für Geflügel*) is prescribed: bonemeal 69, iodised cattle salt (containing 0·01 per cent. iodine) 30, trace elements in the proportions Fe : Cu : Mn = 3 : 1 : 4, 1 per cent.; guaranteed to contain 20 per cent. P_2O_5, corresponding to P 9 and Ca 21 per cent. Complete feeds are to contain 1 per cent. of this mixture, feeds to be given along with grain 2 per cent. With the usual feed mixtures of, roughly, ground cereals 60, milling offals 20, soya grits 10 and fishmeal 10 per cent., the mineral mixture suffices for requirements, provided shell is always available. Further research on the physiological importance of grit is required.

Synthetic vitamins are tending to oust natural vitamin carriers because of their convenience, reliability and reasonable price. The usual mixed feeds normally cover the requirements of vitamins B_1 and B_{12}, nicotinic and pantothenic acids, and choline, leaving vitamins A and D_3 and riboflavin to be added. For these the following recommendations, based on U.S. Nutrient Requirements for Poultry plus a safety factor, are made: complete feeds, vitamin A, I.U. per kg. feed, chicks 4000, young pullets 3000, laying hens 6600, for fattening 4000; feeds to be given with grain, chicks 6600, young pullets 5000, laying hens 11,000; vitamin D_3, I.U. per kg., 300, 300, 750, 300, 500, 500, 1250; riboflavin, mg. per kg., 1·5, 1·0, 1·5, 1·5, 2·5, 1·5, 2·5 for the classes in the same order. It is suggested that vitamin pre-mixes should contain vitamins A and D_3 in the ratio 9 : 1, and that tests of the vitamin content of poultry feeds should include a chick growth test, say with 30 chicks for 6 weeks. Minerals and vitamins are best supplied in separate mixtures.

Antibiotics are still a subject for controversy and are unlikely to be of great economic importance until broiler production is more widespread and there is a greater difference between the prices of fishmeal and soya grits.

In Germany it has been proposed that feeds containing antibiotic should be permitted to contain less animal protein: for complete chick feed, without antibiotic, minimum animal protein 6 per cent., minimum fishmeal 3 per cent., with antibiotic, 4 and 2 per cent., respectively; chick rearing feed 10, 5, 7, 4; complete fattening feed, 10, 5, 7, 4. The amounts of antibiotic proposed are, per kg., complete chick feed and fattening feed, aureomycin or terramycin 10·0 mg. plus vitamin B_{12} 10·0 μg., or penicillin 5·0 mg. plus vitamin B_{12} 10·0 μg.; for chick rearing feed, aureomycin or terramycin 15·0 mg. plus vitamin B_{12} 15·0 μg., or penicillin 7·5 mg. plus vitamin B_{12} 15·0 μg. In view of the great losses from respiratory infections it is suggested that trials be made of special laying meal containing antibiotic, which could be given for a short time only.

MILLIGAN, J. L., WILCKE, H. L., MARR, J. E. and BETHKE, R. M. **Arsonic acid in commercial broiler rations.** *Poultry Sci.*, 1955, **34,** 794–799. [Ralston Purina Company, St. Louis, Mo.]

Large-scale experiments, with 9902 chickens in all, are reported on the effect of 0·005 per cent. arsonic acid on growth on a high-energy broiler ration including fishmeal, dehydrated alfalfa meal, vitamin supplements and bacitracin. The experiments lasted for from 6 to 11 weeks. Group weights only were recorded.

Eleven out of 13 experiments showed that arsonic acid increased final weight slightly or definitely, the average improvement being 0·08 lb. Market grade was better in birds receiving arsonic acid, and feed efficiency was slightly improved. There was no effect on mortality rate,

feather score, pigmentation score or incidence of leg weakness. At slaughter, breast muscle contained less than 0·01 p.p.m. arsenic and liver 0·47 p.p.m.—J. S. Thomson.

2574

LIBBY, D. A., EVANS, R. J., BANDEMER, S. L. and SCHAIBLE, P. J. **Effect of long-time feeding of certain arsonic acids to chickens.** *Poultry Sci.*, 1955, **34,** 972–980. [Dept. Poultry Husb., Michigan State Coll., East Lansing.]

Arsanilic acid, 90 g. per ton feed, or the dodecylamine salt of *p*-chlorophenylarsonic acid, 63 g. per ton, was included as supplement to a starter mash for chicks from day-old to 10 weeks of age. Some of the birds were kept on floors, others in batteries. Both supplements improved growth, and penicillin was equally effective, but a combination of antibiotic and either arsenical was no better than any one of them. The response was greater in the battery-reared birds, and in females. The intake of arsenic from the arsanilic acid was 3 times as great as from the dodecylamide, but the As contents of the liver and edible flesh were almost the same. The As contents of liver and flesh increased when penicillin was given either in combination with arsenical supplements or alone, which suggested that penicillin gave improved absorption of minerals.

From the 10th to the 19th week of life birds were transferred to grass range. In these circumstances the arsenical supplements did not yield any advantage in weight or condition, but the tissues of the birds getting arsanilic acid had lower As contents than in those getting dodecylamide.

During the subsequent year the pullets off the range were housed and laying performance was recorded. The supplements improved egg production, 5 per cent. for arsanilic acid and 3 per cent. for the dodecylamide. Hatchability and efficiency of feed utilisation for egg production were not affected. The As contents of the eggs were higher than in those from birds getting no supplement, but the values found were less than those permitted in fruits for human consumption treated with arsenic sprays, and were not considered dangerous. Contrary to what had been found with liver and edible meat, penicillin did not increase the As content of the eggs.

T. D. Bell.

PEPPER, W. F. and SLINGER, S. J. **Effect of arsonic acid derivatives and a high level of aureomycin on the performance of turkeys to 24 weeks of age.** *Poultry Sci.*, 1955, **34,** 928–934. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

From hatching to 8 weeks of age 4 groups of turkey poults were given an all-mash ration. The control group got no supplement and experimental groups got 3-nitro-4-hydroxyphenylarsonic acid, 45 g., arsanilic acid, 90 g., or aureomycin, 50 g. per ton of feed. Growth of all experimental groups was better than that of controls during the first 4 weeks. The response in females was not as great as in males. From 4 to 8 weeks the groups getting 3-nitro-4-hydroxyphenylarsonic acid and aureomycin maintained an advantage, though reduced, over the controls, but the arsanilic acid group did not.

From 8 to 24 weeks the birds were subdivided so that half of each group was reared on slatted floors and the other on deep litter of wood shavings. The basal ration was of mash and grain, both given free choice, and the supplements were continued. At the end of the period there was no difference in the liveweights of the birds due to the diet. On slatted floors the supplements improved efficiency of feed utilisation, and on deep litter 3-nitro-4-hydroxyphenylarsonic acid also had this effect, though the ratio of mash to grain was less than in controls.

The birds reared on deep litter made better weight gains than those on slatted floors in comparable groups, probably because they ate more mash relative to grain. The incidence of perosis was higher in supplemented groups, and higher in groups on slatted floors.—T. D. Bell.

OLIVARES, E. O. **Value of cow manure extract (CME) on growth of chicks and egg production.** *Philippine J. Animal Indust.*, 1954, **15,** 11–23. [Bur. Animal Indust., Manila.]

Starting, growing and laying rations were made to contain 0, 2·5 or 5 per cent. fishmeal. To each of these 3 per cent. cow manure extract was added. A fourth ration had 5 per cent. fishmeal but no manure.

At 4 months old chickens given the starting and growing rations with 5 per cent. fishmeal and cow manure were heaviest, weighing 1606 g. Those getting 5 per cent. fishmeal weighed only 973 g., and those getting cow manure extract without fishmeal 979 g. Cow manure and 2½ per cent. fishmeal gave birds weighing only 952 g. The highest egg production on the laying rations was on cow manure only, followed by 5 per cent. fishmeal only and then 2½ per cent. fishmeal plus cow manure and lastly 5 per cent. fishmeal plus cow manure. Highest percentage hatchability was on 5 per cent. fishmeal with cow manure. The health of all chicks hatched was good.—T. D. Bell.

GERRIETS, E. and BOBSIEN, R. Vergleichende Kükenaufzuchtversuche nach veterinärhygienischen Gesichtspunkten und Aufzuchtversuche unter Verwendung der Altstreuverfahren. 2. [**Comparative trials in chick rearing from the point of view of veterinary hygiene and experiments in rearing on deep litter. 2.**] *Berl. Münch. tierärztl. Wochenschr.*, 1955, **68,** 372–375. [Abt. Geflügelkrank., Humboldt Univ., Berlin.] English summary.

The 1953 experiment (Abst. 2605, Vol. 24) was repeated in 1954. There were again 4 groups each of 100 Leghorn day-old chicks on sawdust, sawdust with under-floor heating, deep hen litter alternated with garden compost, or horse litter with garden compost. This time the groups on deep litter did better than those on sawdust, but since under-floor heating gave an improvement in both years it was thought that the good effect of deep litter was largely that of a warm floor.

Another experiment was made with 4 groups, each of 20 chicks, from 4 groups each of 10 pullets from the 1953 experiment, kept in the same way over the winter, whose laying performance is to be reported elsewhere (Gerriets and Werner, *Arch. Geflügelzucht,* 1955, in the press). The results were similar to the above, except that there was less difference between the groups on sawdust on a heated floor and deep hen litter, possibly owing to some acclimatisation effect.

The results of all 3 experiments are tabulated together. The mean increase in weight gain with horse litter over the 3 experiments was as much as 11·5 per cent., which is of the order of that produced by including antibiotics in the feed. The birds on deep litter remained healthy, but the practice involves risks and it is considered that veterinary experts should be consulted when new deep litter houses are constructed or old buildings adapted.—W. M. Deans.

HAFEZ, E. S. E. **Differential growth of organs and edible meat in the domestic fowl.** *Poultry Sci.*, 1955, **34,** 745–753. [Fac. Agric., Univ. Cairo.]

Fayomi pullets were killed at ages of one week and at intervals up to 27 months. The carcases were dissected and the growth rates of different parts were compared by expressing the weight as a percentage of the weight of the same part at one week. Most of the organs showed maximum growth during the first 5 months. Early maturing parts were head, liver, blood and digestive tract. Wings, legs, feathers, lungs, kidney and pancreas were intermediate, and ovary, oviduct, spleen and body fat were late-maturing. The yield of edible meat at 5, 12, 21 and 27 months of age was 66, 63, 68 and 67 per cent., respectively. When expressed as percentage of weight at 1 week the rate of increase of the dressed carcase was greater than that of the whole body or giblets. The influence of environment, particularly diet, on development and the practical implications of this are discussed.—T. D. Bell.

2580

ORR, H. L. **Effect of strain, sex and diet on dressing percentage and on cooked meat yield of 10 week old broilers.** *Poultry Sci.*, 1955, **34,** 1093–1097. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

A comparison was made between 10 strains and crosses of different breeds of broilers on the basis of dressing percentage, percentage of ready-to-cook weight and yield of edible cooked meat. Two diets, one containing 5 per cent. and one no animal fat, were tested with each strain, and sexes were compared.

There was no difference due to strain, sex or diet in dressing percentage. Strain and sex had a significant effect on ready-to-cook weight as a percentage of liveweight. As percentages of live or of dressed weight, differences in percentage of edible meat were significant between sexes, but on basis of ready-to-cook weight the differences were not significant.—T. D. Bell.

EGG PRODUCTION

2582

TYLER, C. **The variations in limestone and flint grit consumptions by laying birds.** *J. Sci. Food Agric.*, 1955, **6,** 696–704. [Dept. Agric. Chem., Univ. Reading.]

The amounts of feed, water, limestone and flint grit taken by 5 hens nearing the end of their first laying year were recorded. The birds were given 200 g. laying mash daily, in 2 equal feeds for 8 days and in 4 feeds for 8 days, and had access to

flint grit, limestone grit and water. The Ca carbonate usually included in the laying mash was omitted. Differences between birds and between days were found in the amount of limestone, but not of the flint grit eaten. The greatest consumption of both grits was in the hour before dusk, but this excess was not related to formation of egg shell. Large amounts of both grits were eaten, and there was a great deal of wastage, but sufficient limestone was dissolved in the intestine to satisfy the Ca requirement of the laying hen. The different methods of feeding did not alter the general picture.—T. D. Bell.

MACHLIN, L. J. **An estimate of the leucine requirement of the laying hen.** *Poultry Sci.*, 1955, **34,** 984–985. [Animal Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Four trials are reported on the egg production of hens on diets containing 16 per cent. protein and from 1·0 to 1·6 per cent. leucine. In the first trial an egg production of 78 per cent. was maintained for 4 weeks on a ration containing 1·0 per cent. leucine. In the second, over 10 weeks, birds on a ration containing 1·0 per cent. leucine laid as well as, or better than birds on the same ration with a supplement of 0·2 per cent. leucine. In the third, 8 birds were given a low-leucine ration (1·0 per cent.) and 8 a high-leucine ration (1·6 per cent.) for 12 weeks and the rations were then reversed for 6 weeks. The superior production on the high-leucine ration in the first period was not affected in the second period on the low-leucine ration, and the high-leucine ration in the second period did not improve production in the group on the low-leucine ration during the first period. It is concluded that the leucine requirement of laying hens does not exceed 1 per cent. of the ration (see Absts. 3831, Vol. 18 and 3726, Vol. 23).—J. S. Thomson.

2584

BURGSDORFF-GARATH, A. v. Untersuchungen über die Futterwirkung von Alleinfutter der gepressten und ungepressten Form, sowie Legemehl mit Körnern bei in Legebatterien gehaltenen Hennen. [**Nutritive value of all-mash rations pelleted and unpelleted and of laying mash and grain for hens kept in laying batteries.**] *Arch. Geflügelk.*, 1955, **19,** 407–420. [Garather Geflügelzucht.] English summary.

Three groups each of 108 Rhode Island Red × Leghorn pullets in a battery of cafeteria type were fed from 1 October 1953 to 30 June 1954 on mash pelleted or as meal or on laying mash with grain. They had a 15-hr. day. Other details of management were as in a previous trial (Abst. 5553, Vol. 24). Birds sick, dead or off lay for over 4 weeks were replaced. The feed for the first 2 groups consisted of protein concentrate 10 (fishmeal 70, ground extracted sunflowers 20, dried feed yeast 5, coarsely ground bone 5 per cent.), ground millet 15, ground barley 10, ground oats 10, ground wheat 8, ground maize 7, wheat bran 15, maize gluten feed 10, wheatfeed 6, lucerne meal 5, wheat germ 2, and a 6 : 4 mixture of $CaCO_3$ and bonemeal 2 per cent., with, per kg., vitamin A 2000 I.U., vitamin D_3 1000 I.U., carotene 7 mg., vitamin B_1 2 mg., riboflavin 2 mg. The laying mash given with a mixture of equal parts of maize, barley and sorghum consisted of protein concentrate (fishmeal 40, herringmeal 20, meatmeal 20, soya grits 10, coarsely ground bone 7, dried feed yeast 3 per cent.) 15, wheat bran 18, wheatfeed 15, maize gluten feed 10, ground oats 10, ground millet 10, ground barley 8, lucerne meal 6, maize 5, minerals as above 2, and charcoal 1 per cent., with, per kg., vitamin D_3 1000 I.U., carotene 6 mg., vitamin B_1, 2 mg., riboflavin 2 mg.

The following results show the clear superiority of the pelleted ration: average number of eggs per cage, 149, 93, 107; percentage of eggs in the 2 top grades by egg sorting machine, 70, 47, 57; average weight gain of hen, 430, 120, 370 g.; percentage of hens lost, 28, 51, 44. The average daily weights of feed consumed were 146, 115 and 108 g., and it was concluded that although pellets are doubtless more attractive to hens than meal, their superiority was really due to the hens being able to secure more feed in the limited time available. During the first month the hens on pellets produced more eggs without shells and broken eggs than the others, but this was thought to be a psychological effect of their being on the top storey of the battery.—W. M. Deans.

2585

HAND, C. J. E. and TYLER, C. **The effect of feeding different seaweed meals on the mineral and nitrogen metabolism of laying hens.** *J. Sci. Food Agric.*, 1955, **6,** 743–754. [Dept. Agric. Chem., Univ. Reading.]

The meals were of *Laminaria cloustoni*, *L. saccharina* and *Ascophyllum nodosum*. Control groups got the basal ration only. In each experiment there were 5 consecutive periods of 14 days, and one seaweed meal was used at 10 per cent. in the second and at 20 per cent. in the fourth period.

More water was drunk when seaweed meal was given at either level, and this was attributed to the Cl content of the ration. Weight was lost, and to a less extent egg production was reduced at both levels of seaweed intake, but losses were significant only when 20 per cent. seaweed was given, and could be related to reduced intake of starch equivalent. Changes in Ca, P and N balances were not consistent, and were related to

changes in egg production. There was no effect on chemical composition of the eggs, shell thickness or porosity.

Another experiment lasting 100 days compared seaweed meals at 10 and 15 per cent. levels in rations for laying pullets; the effects on body-weight, egg production and water intake were as before. It was concluded that no benefit is gained from including seaweed meal in laying rations, and at a level of 20 per cent. it may be harmful.—T. D. Bell.

2586

KUMANOV, S. and VOLCHEV, P. Prouchvaniya vorhu vliyanieto na slonchogledoviya, leneniya, ricinoviya i ot grozdovi semki shrotove vorhu noslivostta na kokoshkite. [**Influence of sunflower, linseed, castor seed and grapeseed meals on the egg production of hens.**] *Nauch. Trudove, Selskostop, Akad. "Georgi Dimitrov," Sofia,* 1953–54, **475,** 41–50. Russian summary.

Four groups of 20 Rhode Island hens in their second year received for 6 months rations differing only in containing sunflower, linseed, grapeseed or castorseed meal at the 20 per cent. level. The last group had to be excluded because egg yields fell rapidly for 6 weeks. For the other 3 groups the digestible protein in the ration ranged from 10·83 per cent. with grapeseed to 14·0 per cent. with sunflower seed meal.

The mean egg yields in 6 months were with sunflower meal 113·18, linseed meal 106·82 and grapeseed meal 108·74. The mean intake of fodder units per bird was 27·7, 28·0 and 28·4. Fertility of the eggs and viability were good. There was no difference in liveweight of the hens at the end of the experiment.

It was concluded that all the meals except castorseed can be used at the 20 per cent. level in rations for laying hens. The relatively low protein and high fibre content of the grapeseed meal should be considered when rations are made up. (From summary.)—D. Duncan.

2587

ZNANIECKA, G., ŚLIWIŃSKI, A. and WODZINOWSKI, J. Kiszona rzęsa jako pasza dla kaczek. [**Duckweed silage as a feed for ducks.**] *Rocz. Nauk. rol.* [*B*], 1955, **69,** 259–266. [Inst. Zootech. ZZD Pawłowice.] Russian and English summaries.

The silage was prepared from a 1 : 1 mixture of *Lemna gibba,* L. and steamed potatoes with the addition of 2 per cent. sour milk, and was of good quality. An experimental group of 20 ducks received 200 g. of the silage, a control group 100 g. ensiled potatoes and 10 g. alfalfa hay daily. Egg production in the experimental group was 17·3 per duck and in the control group 12·8. There was a slight increase in weight of the experimental group but a decrease in the control group. There was no effect on fertility or hatchability of the eggs.—J. S. Thomson.

2588

SWART, L. G. **Lupins in laying rations.** *Farming in S. Africa,* 1955, **30,** 404–406. [Stellenbosch-Elsenburg Coll. Agric., Stellenbosch.]

Rations with up to 10 per cent. sweet lupin meal replacing part of the fishmeal did not decrease egg production significantly, but higher amounts, replacing most or all of the fishmeal, did. Egg weight also decreased as the amount of sweet lupin meal increased, and feed eaten per dozen eggs produced rose. There was no effect on hatchability.

Experiments on the feeding of bitter blue lupin meal had to be discontinued because it imparted a bitter taste to the eggs.—J. S. Thomson.

2589

GRAU, C. R., LAU, T. L. and WORONICK, C. L. **Inactivation of gossypol by treatment with phloroglucinol.** *J. Agric. Food Chem.,* 1955, **3,** 864–865. [Dept. Poultry Husb., Univ. California, Davis.]

Preliminary experiments are reported on the inactivation of the gossypol in cottonseed meal by treatment with phloroglucinol, ethyl alcohol and HCl. When the treated product was given to hens it was found to contain little gossypol, as measured by the gossypol-cephalin content of the eggs.—J. S. Thomson.

WORDEN, A. N., BUNYAN, J., DAVIES, A. W. and KLEISSNER, M. **The experimental production of "green yolks" by the oral administration of sodium copper chlorophyllin.** *J. Agric. Sci.,* 1955, **46,** 384–385. [Cromwell House, Huntingdon.]

Green yolks in eggs were produced by giving from 250 to 1000 mg. of water-soluble sodium copper chlorophyllin 100 % daily to Light Sussex hens. The appearance of the yolks was similar to that recorded as occurring naturally. The condition was not produced by an oil-soluble copper complex containing 15 per cent. copper phaeophytin. Sodium copper chlorophyllin was identified in the eggs, indicating that intestinal absorption had occurred.—J. S. Thomson.

2591

PLATT, C. S. **A study of the effect of restricted lighting on January hatched pullets.** *Poultry Sci.,* 1955, **34,** 1045–1047. [Poultry Dept., Rutgers Univ., New Brunswick, N.J.]

White Leghorn pullets hatched in January were divided into 2 groups when they were 13 weeks old, one maintained in natural light, the second with natural light excluded but provided with artificial light for 8 hr. daily, later extended to 14 hr. when the birds were 7 months old. When the birds were 35 weeks old the group under natural light was given supplementary artificial light to provide a 14-hr. day.

Egg production in the group restricted to 8 hr. light was much less than in the normal group, but surpassed it when the light was increased to 14 hr. and was still superior to that of the control group when the latter received supplementary light. Growth of the pullets was retarded under restricted lighting, but at maturity the 2 groups were similar in weight.—J. S. Thomson.

2592

NIGHTALL, E. W. **Egg production and flash lighting.** *Agriculture, J. Minist. Agric. Engl.*, 1955, **62,** 421–424. [Sch. Agric., Univ. Nottingham.]

Flash lighting for 3 periods of 20 sec. during the night improved egg production in White Leghorns. The equipment required is outlined.

J. S. Thomson.

OTHER BIRDS

2595

SCOTT, M. L., HOLM, E. R. and REYNOLDS, R. E. **Effect of diet on the ability of young pheasant chicks to withstand the stress of cold, drenching rain.** *Poultry Sci.*, 1955, **34,** 949–956. [Dept. Poultry Husb., Cornell Univ.]

When pheasants are reared in confinement they are moved from darkened brooders at 4 weeks of age, kept in wire pens for 48 hr. and then allowed out into large enclosures of several acres supplied with hedges and breaks for shelter. If cold rain falls during the first 72 hr. on the open range, many collapse. It was thought that an improved diet might increase resistance to this climatic stress.

When 6 commercial rations and a comparable experimental starting ration were given, growth was satisfactory on all except one, but when artificial rain was applied for 2 hr. during the critical 72 hr. there was no relation between the body-weights of the birds and the percentage which succumbed, except that birds far lighter than normal were all prostrated. The affected birds recovered in 2 hr. in a warm hover.

When an experimental ration containing a high proportion of fishmeal was given resistance was improved, but was not as good as with the commercial ration with which it was compared. When the fishmeal was replaced by livermeal all the birds were affected, and a mixture of fishmeal and livermeal gave intermediate results. The fishmeal diet had 24 per cent. protein and 2·5 per cent. fibre, compared with 28 and 5·5 per cent. in the commercial ration.

Increasing the protein and fibre contents of these latter experimental rations to equal the commercial ration by the addition of fishmeal and oat hulls improved resistance, but they were still not as good as the commercial ration.

When the protein content was increased to 34 per cent. with casein or livermeal and the fibre content was kept at 5·5 per cent. resistance was improved beyond that on the commercial ration, but was poor in all because the stress was also increased. Under less severe stress, with rain which was not so cold or heavy, experimental rations containing 28 and 31 per cent. protein gave complete protection. The possibility that fishmeal, and livermeal and casein, contain 2 different factors that increase resistance is discussed.

T. D. Bell.

FOOD ECONOMICS AND STATISTICS

2596

KRISHNAMURTI, M. **The position of cattle in India.** *Trop. Agric., Trinidad,* 1955, **32,** 278–289. [Pachaiyappa's Coll., Univ. Madras.]

For religious and social reasons cattle in India are not used extensively for beef, but the production of milk and ghee is widespread, and skins and hides also play an important part in the economy of the country. It is as draught animals for agriculture and transport that cattle and buffaloes are most important, and the supply of manure, almost the only source of fertiliser, is vital to agriculture.

A great deal of improvement in all aspects of animal husbandry is necessary. The supply of milk is small compared with the demand, and distribution is unequal, depending on the wealth or poverty of the people. Objections to the slaughter of cattle have led to poor quality of animals both in milk yield and in working capacity, and ignorance has allowed widespread disease. The selection and processing of skins and hides is defective, and manure is not well used. By-products are almost entirely neglected.

Some schemes for improvement have already been introduced, with due regard to social, religious and climatic limitations, by state and national governments, and many more are planned. Projects for the expansion of improved breeding and research on nutrition, dairy and forage improvement and veterinary services, including artificial insemination, are described.—T. D. Bell.

2597

NEWMAN, P. **Some calculations on least-cost diets using the simplex method.** *Bull. Inst. Statistics, Oxford,* 1955, **17,** 303–320.

It is shown how least-cost diets for farm animals can be calculated by a process of successive approximation. It is assumed that the dietary needs of the animals can be stated in terms of daily weights of feed containing certain minimum weights of dietary constituents, and that the content of each of these constituents is known for each of the basic feedingstuffs available. Given the prices of these basic feedingstuffs, the problem is to find that combination of them which will satisfy the dietary requirements at minimum cost. The number of different feedingstuffs required will never exceed the number of constraints.

The essence of the simplex method of calculation, which is described, is to obtain one combination of feedingstuffs which will satisfy the conditions laid down, then to see what amounts of these could be replaced by unit quantities of each of the remaining feedingstuffs in turn. Whichever of these latter would result in the greatest economy is then taken for inclusion in a new mixture, again satisfying the conditions, and one of the original group is excluded. The process is repeated until no further economy is possible.

Least-cost diets are given for cows, pigs and poultry on the basis of the price levels in the years 1950–51, 1951–52, and 1952–53, and illustrate the changes in constituents which may arise as prices change. The practicability of the method is discussed with reference to its use by farmers and by manufacturers of feedingstuffs, and attention is drawn to possible faults, such as failure to take account of palatability.—I. McDonald.

2598

Zunahme der Weltschafbestände und des Weltwollaufkommens. [**Increase in the world sheep population and world wool production.**] *Ztschr. Tierzücht. Züchtungsbiol.,* 1955, **65,** 199.

According to the International Wool Secretariat in London, world sheep population in 1952–53 was 814 millions, a rise of 3½ per cent. since the previous year, and the estimated wool production for 1953–54 was 1979 thousand tons, a rise of some 4000 tons, despite a slight fall in Australia ascribed to drought. Since before the war sheep population has risen by about 8 per cent. but wool production by over 14 per cent. thanks to better breeding and management, especially in Australia, New Zealand and South Africa.—W. M. Deans.

2599

ENGLER, H. L'importanza della pollicoltura nel mondo. [**Importance of the world's poultry production.**] *Zootec. Vet.,* 1955, **10,** 320–330. [FAO, Rome.] English and French summaries.

According to an estimate by FAO, less than half of the world's population received more than 15 g. animal protein daily, and only 17 per cent. received over 30 g., which is recognised as adequate. This deficiency could be at least partly rectified by increasing the production of eggs and poultry for the table. At present there is wide variation in the production of eggs: in the Far East only from 1·8 to 18 eggs per head are available annually. By contrast, in North America and Australasia the number of eggs is from 216 to 378. Within Europe the number in the different countries ranges from 36 to 234. The differences in production of poultry meat are similar in trend. The efficiency of poultry production also differs greatly, and in areas where production is low great improvements are necessary. Many problems are regional in character, but some are universal. These include poultry diseases which need work on an

international as well as a national scale, to improve diagnosis, treatment and organisation ; there must be improvement by vigorous selection for productiveness and resistance to disease, better balancing of rations, and less waste of feedingstuffs. At the same time marketing must be improved, and the economy of poultry production must be stabilised and guaranteed. Relevant statistics should be available. Research and experimental work should be encouraged and extension work should be organised, so that it may be used to reduce costs, increase output and aid stability.—T. D. Bell.

2600

PACI, C. Panorama valdostano. [**A panorama of the Val d'Aosta.**] *Riv. Zootec.*, 1955, **28,** 286–289.

The climate and topography of the Val d'Aosta are described. Although much of the land is high-lying it is sheltered and the climate is mild. It is also dry, and irrigation is given first consideration when the water is harnessed to supply electrical power to the industrial plains. Some of the irrigation schemes in use are of Roman or mediaeval origin.

Fruit is grown in a few regions, but only 4 per cent. of the land is cultivated and the rest is in pastures and meadows. The alpine pastures are second to none. Cattle are maintained on the grassland, and dairying is the economic basis of life in the Val d'Aosta. The cattle are Red or Black Pied Aosta, the former larger and yielding more milk, but not quite so adaptable to mountain conditions. In some of the more remote areas variations in the breed are found, but attempts are being made to establish greater uniformity of the best types. The breeds are believed to derive from Swedish cattle introduced through France 1500 years ago. It was not until the end of the last century that the Val d'Aosta had any extensive trade or intercourse with the rest of Italy.

The most famous export is Fontina cheese, and though the trade is depressed, it is hoped that with the help of legislation if will soon regain its former magnitude.—T. D. Bell.

2601

Aumento da nossa área cultivada no período 1944–1952. [**Increase in our cultivated area between 1944 and 1952.**] *Arq. brasil. Nutrição*, 1954, **10,** 121–123.

The area under cultivation in Brazil in the 3 years 1950–52 was 18 per cent. more than in 1944–46. The greatest increases were in cereals, roots and beans, fruit, onions and alfalfa, the products supplying food, ranging from 21 to 28 per cent. Products cultivated for industrial use, such as cotton, coconut and sugar cane, and for export, cocoa, coffee and castor bean, increased in area by 9 and 15 per cent. respectively. In the same period population increased by 17 per cent.

The increase in cultivated area can be ascribed to the increased mechanisation of agriculture: there were 4000 tractors in 1940 and in 1951 there were 30,000. The wider use of fertilisers, crop rotations and irrigation have also played an important part.

In some cases increased areas under cultivation have meant somewhat smaller yields per acre. When considering the question of food production as a national problem it must be remembered that a large part of the food produced is consumed directly by the producer and does not reach the market.—T. D. Bell.

2602

KENT, N. L. **Out of mouse range.** *Brit. Farmer*, July 1955, p. 1.

The results of 3 experiments on the effectiveness of raised platforms (staddles) in protecting oat stacks against infestation by rats and mice are briefly reported. Compared with stacks built on the ground those built on staddles showed an increase in yield of threshed grain of from 20 to 35 per cent. Grain from the staddle stacks contained 4 to 9 mouse pellets per lb. compared with 14 to 78 in the ground stacks. Grains kibbled by mice numbered on the average 1 per lb. in the staddle stacks and from 23 to 230 per lb. in the ground stacks.—J. S. Thomson.

DIET IN ETIOLOGY OF DISEASE

GENERAL

2603

COOPER, D. M. and GORDON, R. F. **A study of a possible mode of action of antibiotics in chicks.** *J. Sci. Food Agric.*, 1955, **6,** 664–674. [Poultry Res. Stat., Animal Health Trust, Houghton, Hunts.]

Experiments are reported in which depression of growth in chicks was investigated. The depressing agent was transmitted by adding raw gut contents of chicks to the mash and by indirect contact with chicks already showing the depression.

Only 37 and 54 per cent. of these chicks in 2 consecutive years showed a significant response to penicillin in the diet. It was found that if the depression did not appear by the second week of age it did not usually occur later.

Of crude filtrates of liver, lung and intestine excluding caecum from chicks which had shown depression of growth, only the lung filtrate reduced weight gains significantly, and penicillin in the diet counteracted this depressing effect. The possibility of the depression of growth being caused by a sub-clinical infection is discussed.

McSherry, B. J. and Coghlin, C. L. C. **Report of an anaemia of unknown origin in cattle.** *Canad. J. Comp. Med.*, 1955, **19,** 307–312. [Ontario Vet. Coll., Guelph.]

The bull, 7 mature cows and 4 calves in a herd of 35 Holsteins were affected by anaemia in the spring. They were indoors at the time, but were well fed. One cow died, but the others recovered spontaneously during the summer when they went out to pasture. The calves and the bull, in which the signs were more severe, were treated with iron. One calf treated with vitamin B_{12} and folic acid did not respond. The results of blood tests of the affected animals are described. The anaemia was characterised by lack of reticulocytes, and after recovery necrosis of the distal portion of the tails of the calves and the bull occurred. This was probably due to lack of circulation. An experimental heifer was given 100 ml. blood from the bull, but did not develop anaemia. The anaemia could not be classified as haemolytic or haemorrhagic, and the signs seemed too severe for Fe deficiency. The cause of the disorder was not ascertained.—T. D. Bell.

2605

Mariakulandai, A. and Venkataramaiah, P. **Biochemical study of fluorine intoxication. 1. Etiology, prophylaxis and cure. 2. Metabolism of fluorine.** *Indian J. Vet. Sci.*, 1955, **25,** 165–181 ; 183–199. [Sect. Chem., Agric. Res. Inst., Coimbatore.]

1. A disorder of cattle in the Kurnool district of Andhra State (formerly Madras State) was found to be associated with a high F content of river and well waters. F intoxication was made worse by deficiency of P in the fodder available. Slaked lime at 500 p.p.m. was effective in temporarily reducing the F content of natural waters below the toxic level of 1 p.p.m. The feeding of 3 oz. bonemeal daily improved the growth of cattle suffering from a combination of intoxication and P deficiency.

2. Chronic F intoxication characterised by hoof abnormalities, exostoses of the long bones, anorexia, inanition and irritation of the small intestine was induced in South Indian calves by drenching with NaF solution. This treatment had no effect on blood inorganic P, serum Ca or blood F and did not affect the retention of Ca and P as measured in balance experiments. The administration of up to 3 oz. bonemeal daily reduced F retention, particularly in the skeleton, but did not prevent the development of signs of F poisoning.—C. F. Mills.

2606

Wood, P. C. **The epidemiology of white scours among calves kept under experimental conditions.** *J. Pathol. Bacteriol.*, 1955, **70,** 179–193. [Royal Vet. Coll., London.]

During the years 1950 to 1953 calves were kept in isolated communities for the first 3 weeks of life. In each season there was diarrhoea, fatal in some. The mortality increased as the season progressed. The greatest number of deaths were due to *Bacterium coli.* At post-mortem examination septicaemia was found in most, though infection was limited to the intestinal tract and associated lymph nodes in a few. Specific strains of *Bact. coli* were the cause of most deaths, and these were also distributed in the faeces of surviving calves and in the calf pens. In the pens mixed strains were found, but the lethal strains became established periodically ; there seemed to be some relation between the type of *Bact. coli* and the giving of colostrum. Usually septicaemia occurred in calves which did not get colostrum.

T. D. Bell.

2607

Murphy, T. **White scour of calves in West Limerick—an investigation of the disease and its prevention.** *J. Dept. Agric., Republic of Ireland*, 1953–54, **50,** 5–22. [Vet. Res. Lab., Dublin.]

A survey of 133 farms in West Limerick showed that in 1952 white scours occurred on 94 per cent. of the farms, and on 75 per cent. there were deaths due to the disease. Of all calves born 17·1 per cent. died because of white scours. There was a significant correlation between the incidence and severity of the scouring and the time before which, and during which, colostrum was given : if it was withheld for more than 24 hr., or if it was allowed only for a short period, then it did not help to prevent the scours. Significant correlations were found also between the incidence of the disease and the dilution of colostrum when given from the bucket, and between the incidence and the standard of hygiene of the housing.

Field trials in which the dams were given up to 2 million I.U. vitamin A during the weeks before calving failed to show any advantage from this treatment. Giving 450 mg. aureomycin as Aurofac A to the calves in their milk reduced the incidence of white scours from 48·4 to 4·3 per cent.

T. D. Bell.

2608

Raleigh, R. J., Binns, W., Shupe, J. L., Harris, L. E. and Madsen, L. L. **Studies on a cattle disease of unknown origin in Southeastern Utah.**

J. Animal Sci., 1955, **14,** 951–963. [Dept. Animal Husb., Utah Agric. Exp. Stat., Logan.]

From 1 to 5 per cent. of the cattle in the area are usually affected, and the mortality rate among infected animals is nearly 100 per cent. The most obvious signs of the disease are loss of appetite and oedematous swelling of the throat and brisket, hence the popular name of " brisket disease ". A possible cause of the disease was thought to be dietary deficiency of Cu or Co. Trials are reported in which cattle were offered mineral mixtures with or without Cu, Co and Fe, drenched with solutions of trace elements, or given supplementary feeds of alfalfa hay, as preventive measures. Curative treatment of animals which developed the disease included the giving of grass hay or alfalfa hay and Cu sulphate.

The incidence of the disease was reduced by all the preventive measures, more by those including trace elements or alfalfa hay. Of the curative treatments grass hay relieved the signs of the disease temporarily, but they recurred on return to the original pasture. Only treatment with alfalfa brought about a permanent cure.

MILNE, J. A. **The occurrence of phalaris staggers in sheep.** *N.Z. Vet. J.*, 1955, **3,** 119–121. [Dept. Agric., Dunedin.]

In October 1954, 10 out of 19 ewes with lambs grazing on a 2-acre experimental plot showed signs of phalaris staggers. At the time the plot contained, per cent., *Phalaris tuberosa* 75, sweet vernal 12, clover 5 and mixed species 8. The ewes had been on it a month; the weather had been dry until 6 days before the trouble was detected. At first the ewes ate out the clover and weeds and only then ate much phalaris. The signs in affected ewes were as described by McDonald (Abst. 4035, Vol. 12) and others. Two were acutely ill, 4 less so and 4 appeared abnormal only when driven.

Three ewes were given Co, without effect. The 6 worst affected all died or had to be killed; the condition of the other 4 remained unchanged. Post-mortem examination revealed no macroscopic abnormality except areas of greenish pigmentation in midbrain and medulla, the nature of which is under investigation.—D. Duncan.

HOFFMANN, J. A. Die " Darre " (Glossitis gelatinosa circumscripta), eine bisher unbekannte Mangelkrankheit junger Gänse. [**" Darre " (*Glossitis gelatinosa circumscripta*), a hitherto unrecognised deficiency disease of young geese.**] *Berl. Münch. tierärztl. Wochenschr.*, 1955, **68,** 378–380. [Hermsdorf, Thuringia.] English summary.

" Darre ", a disease of goslings between the ages of 5 and 12 weeks, which is found here and there on the forest plateau of East Thuringia, is not new but does not seem to have been described in the literature. A ball-like bright yellow swelling filled with gelatinous material develops at the back of the tongue and leads to death by starvation. Treatment is surgical. No infective agent has been found. The disease is commoner in ill-fed birds and is not seen in those given plenty of freedom. The soil of the region is mostly sand and very poor in minerals and trace elements. Hence it is thought that the disease arises from deficiency of vitamins, minerals or both.—W. M. Deans.

DEFICIENCY DISEASES

2611

STEWART, J., MITCHELL, I. W. and YOUNG, F. J. **Cobalt therapy in farm practice with special reference to hill farms.** *Vet. Rec.*, 1955, **67,** 755–756; 757. [Moredun Inst., Gilmerton, Edinburgh 9.]

A summary of experiments with lambs kept on Co-deficient pasture shows that liveweight gain is roughly inversely related to the intervals between doses of Co. In 3 months lambs getting no Co, 1 mg. daily, 7 mg. weekly, and 28 mg. monthly gained 26, 55, 52, 39 and 30 lb., respectively. Lambs on a Co-dressed pasture gained 57 lb. in the same time.

Experiments in 1952 and 1953 are described in which lambs were kept on deficient or Co-dressed pasture from June to September. Some of the lambs on the deficient pasture got 250 mg. Co monthly. In 1952 after 2 months on the deficient pasture untreated lambs were showing signs of deficiency and they were given a single dose of 250 mg. Co. The weight increase in this group was 31 lb. compared with 47 lb. in the treated group and 53 lb. in the group on the dressed pasture. In 1953 weight gains in the 3 groups, in the same order, were 34, 46 and 49 lb. In the untreated group half the lambs were given a single dose of 250 mg. Co at the end of August, and their liveweight gain during the last month was comparable to that of the other groups.

Massive monthly doses of Co seem adequate to prevent severe deficiency on hill grazing, and could be given during the monthly gathering with little extra work.—T. D. Bell.

DISEASES OF METABOLISM

2613

MARR, A., MOODIE, E. W. and ROBERTSON, A. **Some biochemical and clinical aspects of milk fever.** *J. Comp. Pathol.*, 1955, **65,** 347–365. [Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

Ca, inorganic, total acid-soluble, total and lipid phosphates, and Mg in blood of cows with milk fever were estimated. Some estimations were made also in blood of healthy cows at the ages when they are most susceptible to milk fever. In cows which succumbed to the disorder Ca and inorganic, total acid-soluble and total P were low, but Mg and plasma lipid phosphate were not significantly different from normal. The incidence of milk fever became higher up to the fourth calving. Most cases occurred between 10 hr. before and 96 hr. after calving; the earliest was 14 days before and the latest 4 months after calving.

When cases were considered as severe, moderate or mild, the depression of Ca and P values in the blood serum was significantly greater as severity increased.

Treatment was by intravenous Ca borogluconate. Responses were classified as satisfactory, needing only one treatment, or unsatisfactory, needing more. The former occurred on an average 23 hr. after parturition, and the latter 6½ hr. after. In milk fever occurring before parturition response was generally unsatisfactory. There was no correlation between initial blood values of Ca and P and response to treatment.

A detailed study of the changes in blood constituents during the 10 hr. after treatment with Ca borogluconate showed that in cows giving satisfactory or unsatisfactory responses the change in Ca was the same; it rose sharply, and then fell to the pre-treatment level at 10 hr. The values for serum inorganic P, total acid-soluble P and total P of cows which responded satisfactorily increased sharply, and then gradually throughout the 10 hr. In 3 other cows the increase was less, and was followed by a slight decline throughout the 10 hr.

In some cows which did not respond to Ca borogluconate udder inflation was used. This caused a sustained rise in serum Ca, inorganic P, total acid-soluble P and total P.—T. D. Bell.

2614

BLOOD, D. C., HUTCHINS, D. R. and DUNSMORE, J. D. **The use of calcium laevulinate solution in the treatment of milk fever in dairy cows.** *Austral. Vet. J.*, 1955, **31,** 245–246. [Fac. Vet. Sci., Univ. Sydney.]

Eleven cows with milk fever were successfully treated with calcium laevulinate, 500 ml. of a 13 per cent. solution, mostly intravenously but in one subcutaneously and in another subcutaneously and intravenously. The results were comparable with those expected from sodium borogluconate. The laevulinate is more soluble and less irritant than the gluconate.—J. S. Thomson.

HOFLUND, S., NORDSTRÖM, G. and HALLGREN, W. Acetonämibehandling med natriumpropionat. **[Treatment of acetonaemia with sodium propionate.]** *Nord. Vet.-Med.*, 1955, **7,** 809–825. [Veterinärhögsk., Stockholm.] English and German summaries.

In all, 79 typical cases of acetonaemia were treated, attributed 12 to underfeeding, 60 to overfeeding and 7 to other causes. The sick animals were given free access to best quality hay, and received ½ kg. wheat bran, some roots and 200 g. molasses twice daily, with as much meal and silage as was required to cover their needs. If milk yield was heavy, only 15 to 20 litres were removed, unless there was mastitis in the herd. Treatment was with 50 g. sodium propionate twice daily by mouth for 3 to 5 days. Acetone in blood and urine quickly fell and blood sugar rose in almost all.

If bacteria producing propionic acid have disappeared from the rumen, rumen contents from a healthy animal should be transferred.—I. Leitch.

2617

REBER, E. F. and SCHOETTLE, C. E. **The use of sodium ethyl oxalacetate in the treatment of hypoglycemia and ketonemia in the ruminant.** *Cornell Vet.*, 1955, **45,** 548–555. [Dept. Physiol. Pharmacol., Coll. Vet. Med., Univ. Illinois, Urbana.]

Administration by stomach tube of sodium ethyl oxaloacetate at the rate of 1·5 g. per lb. bodyweight to pregnant ewes starved for from 4 to 9 days reduced blood ketones and increased blood sugar. Subsequent treatments at 24-hr. intervals had less effect. Disadvantages of the treatment are pointed out, causation of diarrhoea and production of ethyl alcohol in amounts sufficient to be toxic. As the level of blood ketone bodies rose during starvation there was a decrease in the lymphocyte : neutrophil ratio, indicating increased activity of the adrenal cortex.

J. S. Thomson.

2618

VIGUE, R. F. **Evaluation of various treatments for ketosis.** *Univ. Pennsylvania Bull.*, 1955, **56,** No. 5, 2–31.

A brief report is given of the use of 10 different methods of treating ketosis in dairy cows with glucose by vein or glycerol or sodium propionate by mouth; by cessation of milking; by exercise and feeding with specially attractive feed; with ammonium lactate or potassium chloride by mouth, adrenocorticotropic hormone or cortisone by intramuscular injection and ketogestin by mouth or intramuscular injection. Of 10 cows treated in each way only a proportion recovered, and in some response to one treatment was obtained when another had failed. The highest proportions of recoveries were with the ACTH and cortisone treatments. The nature of the disease and the choice of method of treatment are discussed.—T. D. Bell.

2619

SHAW, J. C., CHUNG, A. C., OZANIAN, C. H., CHRISTIANSEN, F. J. and RIGHETTI, A. T. **Studies on ketosis in dairy cattle. 19. Glucocorticoid and ACTH therapy in the Los Angeles area.** *J. Amer. Vet. Med. Assoc.*, 1955, **127,** 324–328. [Dept. Dairy, Maryland Agric. Exp. Stat., College Park.]

Treatment of ketosis with hydrocortisone alone or with hydrocortisone acetate was successful in most cases studied. There did not appear to be any advantage from the inclusion of the acetate, and the simultaneous use of Ca and glucose did not improve results. When treatment was given on 2 or 3 successive days recovery was more certain than after a single treatment. If a second treatment was required a larger dose was necessary. Adrenocorticotropic hormone and cortisone were also used to treat some cows, with successful results. The doses necessary were higher than those required in Maryland. This difference is discussed, and possible reasons for ketosis in the cows investigated, which were well fed, are suggested.

T. D. Bell.

2620

SHAW, J. C., GESSERT, R. A. and CHUNG, A. C. **Studies on ketosis in dairy cattle. 20. An evaluation of metacortandracin and 9-alpha-fluorohydrocortisone acetate.** *North Amer. Vet.*, 1955, **36,** 918–920. [Dept. Dairy, Maryland Agric. Exp. Stat., College Park.]

Treatment with 500 mg. metacortandracin or 100 mg. 9-alpha-fluorohydrocortisone was effective in curing cows with primary uncomplicated ketosis. These doses appear to be optimum. The results are compared with those previously found when cortisone acetate and hydrocortisone were used (see above Abst.).—T. D. Bell.

MCCLYMONT, G. L. and SETCHELL, B. P. **Ovine pregnancy toxaemia. 2. Experimental therapy with glycerol and glucose.** *Austral. Vet. J.*, 1955, **31,** 170–174. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

For part 1 see Abst. 5982, Vol. 25.

Pregnancy toxaemia was induced experimentally by starvation in 2 groups of ewes due to lamb in 3 to 4 weeks. Some of the ewes were treated with glycerol by mouth, 3 ml. daily per kg. liveweight, some were treated with subcutaneous injections of 2·5 ml. of 60 per cent. glucose solution and penicillin every 12 hr., and control animals were not treated. Glycerol increased the rate of recovery from 17 to 78 per cent. and glucose from 20 to 75 per cent. Blood analysis showed that in all cases of pregnancy toxaemia blood sugar levels were low. The time taken for recovery ranged from 16 to 120 hr. with glycerol and from 7 to over 240 hr. for glucose. The results were thought to confirm the theory that pregnancy toxaemia is a hypoglycaemic encephalopathy. The treatment should be given as quickly as possible, and should be continued to prevent the recurrence of hypoglycaemia until full return of appetite is obtained.

T. D. Bell.

2622

SETCHELL, B. P. and MCCLYMONT, G. L. **Reversal of the hypoglycaemia of fasted pregnant ewes.** *Austral. Vet. J.*, 1955, **31,** 204–209. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

Reversal of hypoglycaemia in fasted pregnant ewes lasted for 18 hr. when glucose, 60 per cent., 3 ml. per kg. bodyweight, was given subcutaneously, and for 24 hr. when glycerol, 3 ml. per kg., was given by mouth. Exercise, adrenaline, adrenocorticotropic hormone and cortisone also reversed the hypoglycaemia. There was only a small blood glucose response to adrenaline in 2 field cases of pregnancy toxaemia. For treatment of early cases of pregnancy toxaemia glycerol is recommended at the rate of 6 ml. per kg., on the grounds of ease of administration and the comparatively long interval allowable between treatments.—J. C. Gill.

OLOMUCKI, E. and BONDI, A. **Problems connected with ethylene dibromide fumigation of cereals. 1. Sorption of ethylene dibromide by grain.**

BONDI, A., OLOMUCKI, E. and CALDERON, M. **2. Feeding experiments with laying hens.** *J. Sci. Food Agric.*, 1955, **6**, 592–599; 600–602. [Lab. Animal Nutrit., Agric. Res. Stat., Rehovoth, Israel.]

1. Grains fumigated with ethylene dibromide contained bromine in 2 forms, a volatile bromide which disappeared after the grains were aired for 6 to 7 weeks, and a residual, non-volatile, water-soluble bromide. The effects of exposure time, concentration and temperature on the absorption of bromine by different grains is discussed.

2. When laying hens were given grain containing from 180 to 320 p.p.m. free ethylene dibromide laying ceased after from 46 to 56 days; egg weight fell steeply. Smaller amounts also, 10 to 15 p.p.m., produced a decrease of egg weight after 12 weeks. Grain containing no free ethylene dibromide but 120 p.p.m. of residual bromide had no effect on egg size or production. It is concluded that grain fumigated with ethylene dibromide can safely be used for poultry provided it is sufficiently aired.

J. S. Thomson.

CROOKSHANK, H. R. and SIMS, F. H. **Serum values in wheat pasture poisoning cases.** *J. Animal Sci.*, 1955, **14**, 964–969. [Animal Poultry Husb. Res. Branch, U.S. Dept. Agric., Amarillo, Tex.]

Wheat pasture poisoning is a condition found in cattle grazing the wheat crop in Texas and Oklahoma, and generally occurs during periods of lush growth. The course of the disease, which starts with lack of appetite and nervous excitement, and ends with coma and death, if not treated, is described. Treatment is with a solution of calcium gluconate, sometimes with added glucose, Mg, or P. The cause of the disease is not fully understood.

All were at least 2 years old and were pregnant or had a calf at foot. Beef, dairy and crossbred animals were affected. Usually the disease appeared after 60 to 150 days on wheat pasture. Supplements of sorghum or minerals did not prevent the disease. Blood samples were taken also from comparable cows, reared and maintained in the same condition, which did not develop the disease.

The comparison of sera from sick and healthy cows showed that in the sick inorganic P, total and diffusible Ca, Mg and the albumin : globulin ratio were low. Total serum protein, globulin and possibly K were high. There was a wide range in the values found.—T. D. Bell.

KELLEY, G. W. **The effect of roughage on the number of eggs of *Haemonchus contortus* per gram of feces from experimentally infected calves.** *J. Amer. Vet. Med. Assoc.*, 1955, **127**, 449–450. [Dept. Animal Pathol. Hyg., Univ. Nebraska, Lincoln.]

The number of eggs per g. faeces from calves infected with *Haemonchus contortus* was inversely proportional to the amount of roughage given and to the amount of faeces excreted. The total daily output of eggs was not influenced by the amount of roughage in the ration.—G. C. Hunter.

2630

PARNELL, I. W. and DUNN, A. M. (with REEVE, E. C. R.) **Some observations on anthelmintic dosing of hill hoggs in Southern Scotland.** *Brit. Vet. J.*, 1955, **111**, 519–534. [Dept. Zool., Univ. Edinburgh.]

The effects of anthelmintics on the bodyweight, fleece weight and worm egg counts of hill sheep are reported. The treated animals showed greater gains of body and fleece weight than the controls, but the differences were not statistically significant, nor did the different anthelmintics give different effects. An explanation of the lack of statistical significance and the shortcomings of this type of trial are discussed in an appendix.—G. C. Hunter.

2631

GILL, B. S. **Observations on the relationship of thyroidal activity of chicks and caecal coccidiosis (*Eimeria tenella*).** *Indian J. Vet. Sci.*, 1955, **25**, 75–87. [Indian Vet. Res. Inst., Mukteswar-Kumaon, U.P.]

Methylthiouracil, 0·15 per cent., or thyroprotein, 0·04 per cent., was included in the basal mash of chicks 3 days old. A third group received the basal mash only. After 14 days the chicks were infected with 300 sporulated oöcysts each of *Eimeria tenella*. Faecal output of oöcysts was measured for 9 days after infection; then the birds were killed and oöcysts in a suspension of the caecum were estimated. Thyroids were dissected out and weighed. The thyroprotein increased oöcysts 4 times by the seventh day of infection, when most oöcysts were produced in all birds; in those getting thiouracil, oöcyst production was slightly reduced compared with the untreated controls. Thyroids were larger in the thiouracil and smaller in the thyroprotein group.

In a second experiment larger numbers, 200,000, of sporulated oöcysts were given as the infective dose to chicks treated in the same way as in the first experiment. More severe caecal lesions were found in the thyroprotein group at post mortem, but mortality from coccidiosis was lower. Again the opposite was found with the thiouracil group. This was possibly explained by the weight changes, reflecting the appetites, of the 3 groups during infection: during the acute stage from the fifth to the eighth day the birds getting thyroprotein gained weight but the others lost.—T. D. Bell.

7. BOOK REVIEWS

2632

WATERLOW, J. C. (Ed.) **Protein malnutrition. Proceedings of a conference in Jamaica (1953) sponsored by The Food and Agriculture Organization of the United Nations (F.A.O.), World Health Organization (W.H.O.), Josiah Macy Jr. Foundation, New York.** University Press, Cambridge, 1955, pp. xvi + 277.

Sometime in 1953—in spite of the detail in which it is reported the Conference's exact dates are not given—twenty-six participants assembled at the University College of the West Indies. Ten were persons working in that area, three came from South America, two each from Africa, the United States, Central America and India and four were from the headquarters of the international organisations. Under the chairmanship of a delegate from Australia they discussed the condition for which it had been agreed at an earlier meeting in Gambia that protein malnutrition was a sufficiently wide and generally acceptable name. It was natural that kwashiorkor should have been the main theme.

In the tradition of the Macy Foundation there were no prescribed agenda beyond the particular aspects of the subject, biochemical, pathological, clinical and epidemiological, which were the titles for discussion at the four sessions. This book, beautifully produced and illustrated, is a record in direct speech of what was said.

After discussions which seem to have continued at times with keenness tinged with acerbity the members reached the core of the problem at their last session. Perhaps it was the absence from their midst of an agriculturist, an absence which is readily explained by the Conference's general approach to the subject, that led to two footnotes of great significance being added to the Report after the meeting. One makes the point, by quotation from the Second World Food Survey, that "to a very large extent animal and crop production are supplementary rather than competitive and under the climatic and other conditions prevailing in many parts of the world a system of mixed farming gives best results for both". The other comments that for about 80 per cent. of tropical American areas the best use that can be made of the land is to return it to pastures and forests and that as a means for conversion of the forages to highly palatable human foods it is difficult to surpass the dairy cow. The expensive nature of that process was admitted by the Conference; it seems not to have laid sufficient stress on the very great wastage of nutrients that results annually from failure to conserve natural pasture and to integrate stock production with the production of crops.—D. Harvey.

2633

MONNET, P. Diététique du nourrisson, normal et pathologique. [**Feeding of infants, normal and pathological.**] Masson et Cie, 120 Boulevard Saint-Germain, Paris, 1955, pp. 264. Price 1600 fr.

This book has two main defects, one of content and one of style.

The first is the preoccupation of the author with Continental, especially French, literature. This is particularly so in the section on the feeding of healthy infants and may explain why some vitamin requirements, *e.g.*, for riboflavin, are left undecided and Ca requirement is given as only 0·15 to 0·30 g. daily. The preoccupation with French literature, although less marked in the section on the feeding of infants in disease, here also has its disadvantages, as when coeliac disease is discussed

without reference to modern work in the Netherlands and the United Kingdom on the therapeutic use of diets free from gluten.

The second defect, although of no real importance, is none the less irritating. This is the use of abbreviations, for the key to which one must constantly refer to the beginning of the book. Only by so doing may one know, for example, that the discussion on M.F.K. relates to *maladie fibrokystique*.

For the benefit of hospital dietitian and paediatrician the book brings together under one cover information on the requirements of healthy infants in terms of nutrients and foods and the special needs of ill babies. Useful data are given on the composition of foods used in infant feeding but information on breast milk composition is inadequate. The section on therapeutic dietetics covers a wide range of diseases and syndromes such as diarrhoea, vomiting, disorders of water and mineral metabolism, digestive disorders, nutritional dystrophies, coeliac disease, allergies and kidney disease.—F. C. Aitken.

2634

JELLIFFE, D. B. **Infant nutrition in the subtropics and tropics.** World Health Organization, *Monogr. Ser.* No. 29, 1955, pp. 237. Price 25s.

The book opens with a summary of systems of infant feeding in the western world. In the two main chapters which follow and which comprise more than half the book the present infant feeding practices in the subtropics and tropics are described and the present status of nutritional disease among infants there is discussed. These are the more interesting chapters, the first especially so, since much of the information has been brought together after the author's very extensive tour of the Near, Middle and Far East. In a chapter on methods of improving infant feeding the conclusion is that breast feeding alone should be the method of choice for the first six months and that more attention should be paid to the inculcation of feeding habits which will improve the nutritional status of the mother during pregnancy and lactation. The prevention of kwashiorkor is given a separate chapter. The book ends with one on nutrition education in the maternal and child health centre, written in association with Dr. Anne Burgess, Consultant to the Central Council for Health Education, London, and indicating the pitfalls which well intentioned efforts may not always avoid.

Throughout the work there are references to subjects on which more information is needed and to new problems which changing social conditions may pose. It is a most interesting production.

D. Harvey.

UHRY, P. and DUCAS, P. (with ELIACHAR, E.) Le diabète infantile et juvénile. [**Diabetes in infants and young people.**] Masson et Cie, 120 Boulevard Saint-Germain, Paris, 1955, pp. vii + 487. Price 3200 fr.

This comprehensive, well documented treatise reviews and discusses available data on etiology, pathology, symptoms, diagnosis, complications, biochemistry and treatment of diabetes in infants and young people. All of these, except the two last mentioned, are possibly more the concern of the clinician than the nutritionist. Just over 20 pages are devoted to diet treatment. In these the cases for restricted diet and free diet are presented. The authors cautiously conclude that only time will show whether the free diet increases the danger of degenerative complications. Not so cautious is the writer of the preface, Robert Debré, who uses the free diet system with confidence.

There is a brief subject index.—F. C. Aitken.

2637

HAUBOLD, H. Der Kropf, eine Mangelerkrankung. [**Goitre, a deficiency disease.**] Verlag Friedrich Find, Stuttgart-Plieningen, 1955, pp. vii + 343. Price 24 D.M. English summary.

An extensive investigation was made between 1948 and 1954 of the incidence of goitre in Germany, especially among children in Upper Bavaria and Lübeck. It is reported that there was a post-war wave of goitre affecting much of the country and not only the endemic goitre areas. Peasants especially were affected. The children of the American Occupation Forces remained healthy. The goitre was resistant to treatment with iodine, especially in adults.

The goitre is ascribed to deficiency of vitamin A. Night blindness was common. Pastures in endemic goitre areas have a low content of carotenoids, and so has the diet of the agricultural population. This was especially so when home butter-making was forbidden. The war-time and post-war shortage of P fertilisers was blamed for a reduced carotenoid content of crops and pastures.

Endemic goitre and goitre waves are said to be polyglandular disorders; the thyroid hyperplasia is the most noticeable sign. Treatment with vitamins, minerals, protein and small doses of thyroid and pituitary hormones is reported to be effective.

A chapter deals with goitre in livestock. The problem of goitre is discussed from several aspects and there are nearly 800 references.—D. Duncan.

2638

YATES, P. L. **So bold an aim. Ten years of international co-operation toward freedom from want.** FAO, Rome, 1955, pp. 174.

The monosyllables which form the title of this most readable book have been culled from their context in a speech by Mr. Lester Pearson, who was Chairman of the historic First Session of the Conference of FAO at Quebec in 1945. At that meeting, the tenth anniversary of which is celebrated with the publication of this book, Mr. Pearson used the words:

"There have been functional international agencies with more circumscribed objectives and tasks, but FAO is the first which sets out with so bold an aim as that of helping nations to achieve freedom from want".

This account of the agency's performance is by an author who was a member of the staff of FAO for the first six years of its existence. From his intimate association he tells how the boldness of the first Director-General's proposals for the establishment of a World Food Board outstripped the courage which governments were inclined to show in their dealings with the problem of shortages and surpluses, and he describes how timely to the Organization was the help which came to its hand with President Truman's so-called "Point Four" proposals and the creation of the Expanded Technical Assistance Programme.

The descriptions given of the wide variety of its services and the value set on the information which the agency has amassed will provide some of the answers to the less bold critics who have expressed doubt as to the value for money which some of the member nations may be getting in return for their subscriptions. In their smaller way subscribers to an abstracting journal will be interested in this quotation:

"Any abstracting service is comparatively expensive in men and money if it is to provide world coverage and, moreover, such services already existed in one country or another for many sectors of the field. The view prevailed that FAO should encourage existing services to extend and improve their coverage and should itself enter the field only in sectors where it proved impossible to get the job done by some other body. In the event, only in fisheries has FAO undertaken the task."

D. Harvey.

VAN DE WALL, G. and ALVORD, E. D. (Jr.) **A survey of the food and feed resources of the Union of South Africa.** J. L. Van Schaik, Ltd., P.O. Box 724, Pretoria, 1954, pp. xiv + 312.

This survey is in two parts. The first, by the second author, deals with "the nutritional background of the animal industry and the contribution of the industry to human food requirements", the second, by the first author, with "the production and consumption of primary and secondary foodstuffs for human consumption". Each study was made during the tenure by its author of a bursary awarded by the National Council for Social Research and each was submitted as a thesis for a higher degree in the University of Pretoria. The studies are, in a very real sense, twins, identical ones at that, which the authors admit were difficult to keep apart.

The period of reference of the statistics on which the arguments are based is the 30 years from 1917 to 1946 and, when it is remembered to how great an extent in the 20th century war has affected the fortunes of the political unit which we now know as South Africa, the advances made by the Union in the years of peace are all the more remarkable. None could be more conscious than the authors of the limitations of the statistics which were their raw materials, and each has something to say on possible improvements in their collection. In this respect the survey as a whole, by indicating the gaps which exist in the information available in the Union, will provide an object lesson to other countries less well supplied.

In spite of these limitations some interesting findings emerged and reference to some has already been made by Dr. F. W. Fox in a series of articles in the *South African Medical Journal* (see Absts. 3594, 5556, Vol. 24; 1127, 2612, 4068, 5542, Vol. 25). Two conclusions, one that 90 per cent. of the digestible protein and 86 per cent. of the total digestible nutrients which are available for feeding stock in the Union are furnished by natural veld pasture, and the other that in human nutrition there is need for an annual production of 200,000 more tons of beef, underline the necessity for the fullest use and the most careful conservation of pasture. It is in providing suitable supplementary feeds for use with this pasture that the problems arise, in agronomy of finding species that will level the seasonal variation in nutritive value, and in agricultural practice of avoiding the loss of many millions of tons of digestible nutrients which is shown to be an annual occurrence.

When a subsequent edition, the demand for which will be irresistible, is planned, consideration should be given to increasing the scale of some of the diagrams and especially of the maps in order to make them more easily legible.—D. Harvey.

SWIFT, R. W. and FRENCH, C. E. **Energy metabolism and nutrition.** The Scarecrow Press, Washington, D.C.; Bailey Bros. and Swinfen, Ltd., London, 1954, pp. 264. Price $5.75

The preface tells us that this book is presented "from the standpoint of the teacher having seniors and graduate students under his direction". The peculiar mixture of ingredients argues a much more catholic education in the Department of Animal Nutrition, Pennsylvania State University, than would easily be found in the United Kingdom. Human and animal nutrition are discussed side by side, as if those who are concerned with stock feeding must also be interested in the almost medical problems of obesity and diabetes in man.

The book is perhaps at times too learned for students, and is scarcely argumentative enough for the research worker; unless the shattering of current precepts moves him to fresh efforts, for instance after reading the following: "As a result of long usage and tradition therefore, the T.D.N. system has survived though wholly undefended, so far as the authors are aware, by any research worker in the field of nutrition". Or this: "Group feeding has unquestionably contributed much in the early days of what might be called primitive investigation but is of little or no value in the more specific detailed requirements of present day research". Some of the judgments sound deliberately provocative, as: "It is invariably the case that the student wrongly chooses the 'moderately active' or 'physically active' classification when 'sedentary' should be applied. The latter category should be used for the great majority of our population. . . ." So long as there are any heavy workers, the student cannot always be wrong. The dictum might have been more moderately put: "Most of our population require no more than the 'sedentary' allowance." Still, if the aim is instruction the mode must no doubt be didactic, and the book contains in small space lots of information that is often required but not easily memorised or readily found in larger textbooks.—I. Leitch.

JUKES, T. H. **Antibiotics in nutrition.** Medical Encyclopedia, Inc., New York, Antibiotics Monographs 4, 1955, pp. 128. Interscience Publishers, London.

The writer who has to deal, in less than 90 pages, with 439 publications, many of which report contradictory experimental findings, is in a difficult position. His account of the subject must, almost inevitably, become a catalogue of claims made or repudiated. Many of the later pages of this compilation are of this nature and will interest the more specialised workers. The earlier ones, which give a history of the use and a review of the mechanism of action of antibiotics in nutrition, will be more to the liking of the general reader. Whatever the level of his approach, the reader will not fail to conclude that much still remains to be clarified in connection with the nutritional effects of these thaumaturgic drugs.—D. Harvey.

HAMMOND, J. (Ed.) **Progress in the physiology of farm animals. Volume 2.** Butterworths Scientific Publications, London, 1955, pp. 395–740 + xv. Price 45s. Postage 1s. 8d.

The reviewer of Volume 1 of this publication (Abst. 1547, Vol. 25) said that, "Perhaps the most worrying feature of the book is that it reveals the conflict between those who think solely in terms of animal production and those who adhere to a physiological approach". Volume 2 appears to represent a continuation of Dr. Hammond's efforts to reconcile these conflicting personalities. Perhaps it might have been better to sacrifice individual expertise in the interests of unity of approach.

In the first chapter the treatment of growth in a general sense does not do justice to the theme. Later, it hardly gives enough attention to the effects of antibiotics and the use of hormones in fattening. There is some overlapping with the next chapter, on conformation and body composition. This chapter, in contrast, is extremely thorough and runs to more than 100 pages, and the author is one of those more successful in combining the practical with the academic. But he passes over some interesting implications. For instance, in discussing heterogonic growth in sheep the statement is made that in the foetus of 56 days' gestation the abomasum makes up 17·2 per cent. of the total weight of the stomach [not *four* stomachs], while at birth it has increased its proportion to 55·8 per cent. This is explained as "clearly functional"; but is it not as interesting that at first the stomach develops in almost its adult proportions, the relative increase in the abomasum coming quite late in gestation?

The chapter on wool growth is especially authoritative, though it is a pity that we must look elsewhere for the bibliography. Animal behaviour is rightly given its place; it can no longer be regarded as a neglected subject. The remaining chapters deal with locomotion in quadrupeds, interestingly dealt with, and with egg production in poultry, making altogether a mixed bag indeed.

Altogether, this is another stimulating book, which provides information not always as new as might be expected from the title, but with enough freshness of approach to interest students of most ages from the undergraduate onwards. Good

paper, large clear print and well produced illustrations are its material assets.—D. Duncan.

FISHWICK, V. C. **Pigs: their breeding, feeding and management.** (Revised edition edited by Biggar, W. A.) Crosby Lockwood and Son, Ltd., 39 Thurloe St., London, S.W.7, 1953, pp. 228. Price 18s.

Chapters deal with the rearing and feeding of young pigs, breeding gilts and boars, and fattening for bacon or pork. The market requirements are described. The chapters on housing, health and disease and feeding have been rewritten in the light of new knowledge since the last edition in 1951. Policy as regards choice of breeds, buying or rearing, integration of pigs into the economy of the farm, and the costing of the pig enterprise are discussed. The book is based on the experience of the author and the editor and is designed to appeal to the practical pig-keeper.—T. D. Bell.

2644

COMAR, C. L. **Radioisotopes in biology and agriculture. Principles and practice.** McGraw-Hill Book Company, Inc., London, New York, 1955, pp. xiii + 481. Price 67s. 6d.

In the preface the author states that "a primary purpose of this volume is to bring home to the student and investigator an appreciation and understanding of how radio-isotopes can fit into his programme and then to show how the experimental work can be undertaken". This expresses well the choice and arrangement of material. The first chapter deals in some detail with the principles of tracer methodology: this is of particular value, since a thorough understanding of the theoretical basis of tracer kinetics is necessary for the correct interpretation of experimental results. The next chapters are concerned with fundamental difficulties in tracer methods and with radiation hazards. A detailed account is then given of the design and equipment of laboratories and of basic procedures with animals, plants and soils. The fifth chapter describes general methods for the assay of radio-active isotopes. Chapter 6 is a summary of the properties of individual isotopes and suitable procedures for their use. This is a valuable guide to the choice of an isotope for a particular investigation and occupies more than one-quarter of the book; typical studies are described and practical hints given on the use of the isotopes discussed. The last four chapters are concerned with the principles and application of autoradiography, paper chromatography, ion exchange and radio-activation analysis.

On account of the detailed treatment of theoretical and practical fundamentals this book should be of great value to workers beginning to use radio-active isotopes. The large number of references and the wide range of the subject material drawn upon should make it a useful work of reference for all biochemists.—H. G. Bray.

2645

HOLMAN, R. T., LUNDBERG, W. O. and MALKIN, T. (Ed.) **Progress in the chemistry of fats and other lipids. Volume 3.** Pergamon Press, London; New York, 1955, pp. vii + 475. Price 70s.

In this book, consisting of 11 "short monographs" bound together for convenience, 6 are of direct interest to the biochemist and to workers in the field of nutrition; it is with these 6 contributions that the present review will be mainly concerned.

An account of problems in the parenteral administration of fats to animals and man given by Dr. Smith Freeman (Chicago) directs attention to the many difficulties which must be overcome before intravenous injection of lipids can be considered a safe means of administering a fluid rich in energy and of low osmotic pressure to undernourished and sick persons. Included in this survey are sections dealing with conditions affecting the stability of fat emulsions, toxic reactions to infused emulsions and evidence relating to the utilisation of injected lipids.

Professor Henrik Dam (Copenhagen) reviews current knowledge of the biochemistry of the fat-soluble vitamins A, D, E and K, to each of which a separate section is devoted; short accounts are given also of the guineapig antistiffness factor and of the factor which prevents gizzard ulceration in chickens.

The formation of animal fats, with special reference to triglycerides, is discussed by Dr. F. B. Shorland (Wellington, N.Z.). A survey of research concerned with the fate of dietary lipids and the endogenous synthesis of fatty acids, including branched-chain acids, is followed by considerations of the dynamic state of body lipids and conditions determining the fatty acid composition of depot fats. Finally, changes in the pattern of fat metabolism during the course of evolution are discussed; it is suggested that animal species can be divided into 3 main classes, (1) species which deposit dietary fat only, *e.g.*, fishes, (2) species which deposit exogenous and endogenous fat, *e.g.*, amphibians, reptiles and non-ruminant mammals, and (3) species which deposit mainly endogenously-produced fats, *e.g.*, ruminants.

Modern theories of the glyceride structure of fats (so often characteristic of a plant or animal species) and mechanisms regulating the composition of natural fats are dealt with by Dr. Vander Wal (Chicago) in a critical survey of the "even distribution theory" of Hilditch, the "random

and partial random distribution theories" and the most recently proposed "theory of restricted random distribution" of Kartha. The latter is regarded by Vander Wal as the most complete and ingenious theory yet produced.

The Swedish workers Professor Bergström and Dr. Borgström have collaborated to write a valuable, critical account of the intestinal absorption of triglycerides and their hydrolysis products. Recent developments in methods (surgical and analytical procedures, including the use of radioactive isotopes) are discussed, and many of the authors' own experiments on the hydrolysis of triglycerides by pancreatic lipase *in vitro* are described. A valuable addendum to this chapter is a short description, illustrated with photomicrographs, of the structure of the intestinal mucosa by F. Sjöstrand and H. Zetterqvist.

Dr. L. T. Samuels (Utah) has contributed an extensive review of the metabolism of steroid hormones, which includes a discussion of acetate as a precursor of steroids and of cholesterol as a precursor of steroid hormones. The transport of steroid hormones and their overall metabolism and metabolism in specific tissues are discussed in considerable detail.

The other 5 chapters are mainly of interest to the pure chemist; they include "Solutions of Soap-like Substances", "Synthetic Detergents" and "Oxygenated Fatty Acids", together with accounts of the application of low-pressure fractional distillation and low-temperature crystallisation to analysis of lipids. In their preface the editors recognise a division between "chemistry and technology of fats" and technological advances will in future be covered in separate series of books.

The book is well produced and the price is not unreasonable. Each chapter carries full references to the literature and, in addition, author and subject indexes appear at the end of the volume.

G. A. Garton.

LILLIE, R. D. **Histopathologic technic and practical histochemistry.** The Blackiston Company, Inc., New York, 1954, pp. ix + 501. Price 56s. 6d.

The first edition of this book was published in 1947 under the title "Histopathologic technic". The present work consists of a practical account of methods for the histological and histochemical examination of a wide variety of materials for many constituents. The first few chapters are concerned with equipment and fundamental techniques such as microscopy, fixation, sectioning, staining and mounting. Then follow chapters concerned with the recognition of nuclei and nucleic acids, amino-acids and characteristic chemical groupings, cytoplasmic granules, enzymes, endogenous and exogenous pigments, minerals, carbohydrates, lipids and connective tissue fibres. Finally, accounts are given of the examination of bacteria, protozoa and other parasites, of glia and nerve cells and fibres and of the treatment of hard tissues and other special procedures, *e.g.*, vascular injection, corrosion, autoradiography and micro-incineration. The chief characteristic of this book is the detail in which the procedures are described, so that it should be possible for any worker familiar with general histological technique to carry out any examination with a minimum of difficulty. Another useful feature is the general discussion of the histological properties of tissues and tissue components which forms a background to the detailed practical instructions which are given. This book clearly embodies a great deal of practical experience and will be of value to many workers who use histological methods.

9. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.

Vol. 4, No. 12, December 1955, pp. 72. Price $0.50.

P. 1. The world food and agricultural situation. Statement by Director of Economics Division at Eighth Session of FAO Conference, November 1955.

P. 8. Progress and developments in the selective expansion of agricultural production and consumption. 1. The subject is considered regionally. In this part North America, Oceania, Western Europe, U.S.S.R. and Eastern Europe and Latin America are treated.

Vol. 5, No. 1, January 1956, pp. 48. Price $0.50.

P. 1. Progress and developments in the selective expansion of agricultural production and consumption. 2. In this part Africa, Near East and Far East are treated. General conclusions are given in relation to the policy of " progressive adaptation of agriculture to the changing need of a country or wider region " proposed at the Seventh Session of FAO Conference, November 1953.

Vol. 5, No. 2, February 1956, pp. 56. Price $0.50.

Commodity Reports. Rice No. 6. Rome, Italy, December 1955, pp. iii + 49. Price $0.25.

Commodity Policy Studies No. 9. The stabilization of the olive oil market. Rome, Italy, 1955, pp. 55. Price $1.00.

Commodity Series Bulletin No. 27. Cacao. A review of current trends in production, price and consumption. Rome, Italy, November 1955, pp. 99. Price $1.00.

In a chapter on the outlook for consumption and prices there is information showing that, for cocoa, not all countries reach the same income elasticity of demand at the same level of income. They can be grouped according as their income elasticity is low, Australia, New Zealand, Sweden, Canada and especially United States of America ; medium, Norway, France, Belgium and Denmark, or high, as in most other countries. Data are insufficient to allow prediction as to whether in the United Kingdom and Switzerland, countries with high rates of consumption, these rates will continue to rise with income or whether a saturation level will be reached. Data for surveys of consumption in Germany 1927–1928, Denmark 1939–1940 and the United States, 1935–1936 are discussed.

Agricultural Studies No. 30. Joint FAO/WHO Expert Committee on meat hygiene. First report. Rome, Italy, December 1955, pp. 52. Price $0.60. Also issued as WHO Technical Report Series No. 99.

Report of the third special meeting on the economic aspects of the rice industry. Bangkok, Thailand, 30 September - 7 October 1955. Rome, Italy, 1955, pp. v + 49. Price $0.50.

Delegates attended from 17 countries and their main concern was a solution to the problem of fluctuations in international trade. On the particular question of increasing human consumption it seemed possible that a rise in income, in certain areas such as Africa, might lead to an increase in the use of rice at the expense of millets and sorghums but in the rice-producing countries the same change might lead to a decrease in its use. The high price of rice in relation to that of other cereals has given rise to greater importation of wheat into Japan. The main recommendations to governments were that they encourage the use of rice directly as food or feedingstuff or for industrial purposes and indirectly by eliminating fiscal burdens which may add to its cost ; that they assist financially in creating national stocks ; and to FAO that it help towards these ends by referring the economic aspects to an intergovernmental group appointed by its Committee on Commodity Problems and by furthering the work of the *ad hoc* Working Group which it created after the Rangoon meeting (see p. 593, Vol. 25).

Agriculture in the world economy. Rome, Italy, November 1955, pp. vii + 76. Price $1.00.

This text, which is well illustrated by 26 figures, most of which are two-colour, describes the position held by agriculture in relation to the other industries of the world. It is complementary to an earlier publication *The Farm and the City* (see p. 973, Vol. 23). It is argued that, as a result of the antipathy towards agriculture which arose at the time of the Industrial Revolution, its true position in the world's economy and its value as an outlet for manufactured goods have not been appreciated. Because of the rapid rate of increase of the world's population and the present low standard of feeding of so many of its peoples there is an urgent need for agricultural expansion.

N.A. and R., April 1956

In the coordination of the efforts of individual governments FAO must play a vital role.

Report of the Council of FAO Twenty-second Session, 28 October–2 November 1955 ; Twenty-third Session, 26 November 1955. Rome, Italy, December 1955, pp. vi + 65.

Bibliography of land and water use in Europe. Rome, Italy, 1955, pp. 347. Price $1.50.

10. DEPARTMENTAL AND OTHER REPORTS

CANADA

Department of Agriculture, Experimental Farms Service. Range Experimental Farm, Manyberries, Alberta, Progress Report 1948-53. Pp. 45.

Gains of cattle at different rates of grazing.
Seasonal trend in nutritive value of range fodder and gains of grazing cattle.
Consumption of salt and phosphorus supplement by range cattle.
Supplemental feeding of pregnant ewes.
Supplemental feeding of cobalt to sheep.
Palatability of native range plants.

EAST AFRICA

East African Agriculture and Forestry Research Organisation Annual Report 1955. Record of Research for the Period 1st January 1954 to 30th June 1955. Pp. 116.

Digestibility of oat silage.
Variations in the ratio of hay to silage fed appear to alter the calculated feeding value of the silage. The addition of a readily available carbohydrate (cassava) to a hay ration decreased the digestibility of the crude fibre of the hay.
Nitrogen studies on herbage. Nitrogen fractions in relation to feeding value.
Carbohydrate studies on herbage. Changes in lignin, cellulose and xylin during growth.

INDIA

Synopsis of the work on nutrition. Bengal Immunity Research Institute, Calcutta, 1955. Pp. 10.

Processing of food proteins for utilisation in health and disease (protein hydrolysate, liver and liver extracts).
Pulse proteins and their nutritional improvement.
Vitamins : cause of deterioration of vitamin A in vegetable and mineral oils and effect of anti-oxidants : absorption and utilisation of different forms of vitamin A alcohol, acetate and palmitate : utilisation of vitamin A given orally or parenterally : stability of B vitamins.
Fat emulsions for oral and parenteral use.

INTRODUCTION

WITH the realisation that New Zealand's population is likely to increase from the present total of just over two million people to three million in the early 1970s, considerable thought has been given by some experts on how production from the Dominion's farm lands can be increased, first to meet the needs of this expanding population, and second to provide them with the additional imports required to maintain, and if possible to improve, living standards. In his report to Parliament in 1953 and again in 1955 the Director-General of Agriculture drew attention to the task and stated that an increase of 60 per cent. in livestock numbers was necessary for a population of three million.

The task before the farming industry is one of no small order, and it is of interest to survey what is being done at present towards reaching this production goal and to review some of the problems.

PHYSICAL BACKGROUND

The Dominion covers about 66 million acres, of which about 44·2 million are occupied for farming. It is largely a mountainous and hilly country, less than one-quarter of the land surface lying below the 650-foot contour and, of the farming land, it is estimated that 28½ million acres (64 per cent.) are too steep to be cultivated by implements. Both islands are divided broadly into eastern and western regions by the main mountain axis, and the area of "easy" farming lowlands is very small, confined mainly to coastal strips and river valleys which are usually separated in such a way as to make road construction and maintenance difficult and costly.

Although New Zealand has some very wet regions and one semi-arid one, in general the farming lands have an annual rainfall between 30 and 70 inches, which is evenly distributed. The climate is temperate and nowhere is it necessary to house cattle at any season of the year. In the North Island grass grows for the greater part

of the year, but in the South Island growth is checked during the colder winter months and supplementary fodder has to be provided. Much of the country enjoys 2000 or more hours of sunshine a year, and even certain regions which have an annual precipitation of over 100 inches still have more than 1900 hours of sunshine.

It is true to claim that New Zealand's greatest asset is its climate.

HISTORICAL DEVELOPMENT

New Zealand can look back on little more than 100 years of farming history, and today the adjustment of farming to environment is still going on. Its broad characteristics, sheep farming for meat production and dairy farming for the production of butter and cheese, have become established only since the introduction of refrigeration in 1882. The first organised settlers arrived in the 1840s and for the first 10 years their main task was to produce food and animal products for themselves. The Crown Land Ordinance of the early 1850s made it possible for settlers to take up large areas of land for grazing, and Merino sheep from Australia were soon brought in to stock these large runs.* Within 10 years much of the south-eastern portion of the North Island and all of the tussock grasslands of the South Island were occupied and used for sheep farming for the production of wool.

The discovery of gold in Otago in 1861 resulted in a considerable increase of population and the consequent creation of a good domestic market for cereals and other farm products. That event, with a drop in world prices for wool, brought about a change in the farming pattern on the easily cultivated, flat land of Canterbury; in the early 1870s several run holders began to grow wheat on a large scale, and for a time "bonanza" wheat-farming was common. Some run holders grew as much as 5000 acres of wheat, and the area under wheat increased spectacularly from 78,000 acres in 1870 to 390,800 acres in 1883; for some time New Zealand was a wheat-exporting country.

While the Canterbury farmer was making the change from sheep farming for the production of wool to mixed farming for the production of wheat as well as wool, an onslaught on the bush and scrub vegetation of the North Island by the "bush burn" technique began. Under that system the larger forest trees were felled and fire reduced them and other forest growth to a wilderness of blackened and charred stumps and logs; then, before the ashes were cold, pasture seed was broadcast by hand. So was created much of New Zealand's hill pasture land, and also much trouble for the future, for in many areas of higher rainfall reversion to the prickly bushes of manuka (*Leptospermum* spp.) soon took place and the new settlers had to retreat. Only during the past decade has another vigorous attempt been made to establish good pastures on some of that deteriorated country.

The next distinctive phase of development began in the 1890s, but it was foreshadowed already in 1882 by the first successful shipment of frozen meat to Britain from Dunedin. By 1895 refrigeration was well organised commercially, new primary industries were possible, and there was an upward turn of prices for primary produce. A living could now be made off a smaller area of land and there arose a demand for small areas from the farm worker with limited financial resources.

The Liberal Party, which came into power in 1891, helped to provide these holdings by passing legislation to stop land aggregation and to recover land already alienated from the Crown. The Crown also purchased large holdings, subdivided them, and leased the areas to small farmers on favourable long-term leases. There now occurred a change from sheep farming for the production of wool and from "extensive" wheat production to a more mixed farming in which the output of frozen meat, butter and cheese assumed greater significance. Returns from fat lambs supplemented returns from wool, and emphasis was placed on carcase as well as fleece. A great new dairying industry appeared as soon as milk products could be transported successfully half-way round the world. The new farmers on their smaller holdings, who wished to carry the maximum number of stock, became leaders in the adoption of better farming techniques, and thanks to their enterprise the present farming pattern of the Dominion was established by 1920.

From 1920 until the end of the second world war techniques for the intensive cultivation of grassland were increasingly applied to a relatively small area of good flat and undulating land, and during that time these New Zealand farmers became among the most expert in the world in the production and use of high-quality pastures. Adaptation of some of the grassland techniques to hill country, particularly in the North Island, has been the latest development in farming, and it is to those areas of hill country that the Dominion will turn to obtain part of the increase in production necessary for its expanding population.

PRESENT FARMING SYSTEMS AND PRODUCTION

Present farm management systems can be classified according to product and according to type of pasture. Briefly, the systems are :

* A term applied to pastoral land held under lease or licence, generally extending to several thousand acres.

(1) Very extensive pastoral farming. Product : wool.
(2) Extensive pastoral farming. Products : wool and store and breeding stock.
(3) Semi-extensive pastoral farming. Products : wool, store and breeding stock, and some fat stock.
(4) Semi-intensive pastoral farming. Products : wool, fat stock and some store and breeding stock.
(5) Intensive farming. Products : (*a*) meat, or meat and cash crops ; (*b*) dairy products.

Very extensive pastoral farming is confined principally to the tussock grassland of the "montane" country, mountainous country to the east of the Southern Alps in the South Island, a region of large sheep stations which are devoted mainly to the production of fine wools. Here Merino and half-bred sheep predominate. The early pastoralists found that the fresh green growth which followed the burning of the tussock cover was eaten readily, and the discovery led to the regular and indiscriminate burning which has contributed to the depletion of large areas of once valuable grazing land. Actually it is the small plants, weeds and grasses which grow in the shelter of the tussocks that provide the main sustenance for the grazing animal.

Because of the grave risk of losses from snow, management in the extensive high-country runs (see footnote, p. 566) in the South Island hinges on the division of the available grazing area so that sheep can be moved to lower and safer country for the winter. Cattle have never been of much importance in that area, and although recently there has been a slight increase in numbers, in no section of the tussock country does the ratio of cattle to 100 sheep shorn exceed 3 and in many areas it does not exceed 1. The ratios are small compared with those in parts of the North Island such as the east coast district north of Gisborne, where the ratio is nearly 20.

The main product of the very extensive pastoral farming is fine wool, since, owing to the comparatively low rate of lambing and the risk of losses from snow, there is seldom any surplus stock for disposal.

Extensive pastoral farming, covering the production of wool and store and breeding stock, is carried on in the lower tussock areas of the South Island where danthonia (*Danthonia pilosa*) and browntop (*Agrostis tenuis*) are now important constituents of the sward, and on the danthonia and browntop surface-sown hill pastures of the North Island. The flocks and herds of the extensive pastoral areas supply the store lambs, wethers, cattle and breeding ewes required for the intensive farming areas where store animals are fattened on grass or fodder crops and the breeding ewes are mated for the production of export lamb.

The North Island extensive pastoralist keeps cattle as well as sheep, the proportion being usually 1 to every 10 sheep, but in the areas of higher rainfall the proportion is as high as 1 to from 5 to 7 sheep. The cattle can be used to clean up surplus summer growth of grass and crush out fern and other undesirable vegetation.

On surface-sown hill country of moderate fertility or where fertility has been built up by top-dressing, the pasture lands are capable of producing some fat stock, so that extensive pastoral farming grades into semi-extensive and semi-intensive pastoral farming. Surface-sown hill country of moderate fertility produces wool, store and breeding stock, and some fat stock. Top-dressed surface-sown hill land produces wool and fat stock and some store and breeding stock.

Intensive farming is practised on the flat and undulating land where the pastures, mixtures of grasses and clovers, have been established after ploughing the land. In the warmer and rainier areas the intensive grazier relies almost entirely on grass for the production of meat, and in some of the areas good land carries up to 6 and 7 ewes per acre, with their lambs, all the year round. He buys culled-for-age and surplus 2-tooth ewes from the extensive pastoralist and mates them with Southdown rams for the production of export lambs, which are often fit for slaughter at 30 or 40 lb. dead weight by midsummer. He also fattens store lambs, wethers and beef cattle purchased from the extensive pastoralist. In drier or colder areas grass has to be supplemented with fodder crops. In areas of low rainfall rape is grown for summer fattening of lambs ; in the colder areas turnips, swedes and green fodders are eaten where they grow in winter. On land of high fertility in the drier areas cereal, pulse, pasture seed and other cash crops are produced in rotation with grass and fodder crops. New Zealand cannot, however, be classed as a large-scale producer of arable crops and such crops cover little more than 1 million acres. The general aim in crop production is to satisfy domestic requirements, but considerable imports of wheat are needed.

Dairy farming is a form of intensive grazing on permanent grass. Hay and silage made from the surplus growth of summer pasture are used as supplementary feed, and with grass they form almost the whole feed of dairy cows. Seldom is purchased fodder brought on to a farm. On good land a dairy cow can be maintained on as little as from 1 to 1½ acres, which means a self-contained production of about 250 lb. butterfat per acre. Dairying tends to become the dominant farming industry where the rainfall is more than 40 in. per annum. North Auckland, Auckland, Taranaki

and Southland are the chief dairying districts. Considerable attention is paid also to meat production in those districts, and it is the chief activity where the rainfall is less than 40 inches. Cereal and other cash crops together with production of meat assume greater importance in areas where the rainfall is from 25 to 30 inches, the Canterbury Plains being the chief area of arable mixed farming.

New Zealand farming is highly specialised and mechanised and is fundamentally grass farming. There are about 38 million sheep, which produce about 328,000 tons of meat and 420 million pounds of wool a year. The 2·6 million head of beef stock and 3·1 million head of dairy stock together produce about 178,000 tons of beef and 21,000 tons of veal. The 2 million milking cows produce about 190,000 tons of butter, 105,000 tons of cheese, and about 70,000 tons of milk powder and condensed milk, as well as whole milk for just over 2 million people. Agricultural production forms the greater part of the Dominion's primary production, and of the wool, meat and dairy products approximately 75 per cent. by weight is exported.

Though the dairy cow and the sheep bring in the greater part of the Dominion's overseas revenue, other farm enterprises play a part in satisfying local market requirements or providing some export revenue.

Poultry farmers generally satisfy the local market and bee-keepers produce a small surplus of honey for export. The country is self-supporting in hops, and part of the local requirements of tobacco are met by tobacco growers in the Nelson and Motueka districts in the northern part of South Island. The orchards near Hastings in the Hawkes Bay District and in the Nelson District grow sufficient apples and pears to meet local requirements and to export annually about 1½ million cases of apples (about 40 lb. to the case) per annum, mostly to the United Kingdom. Market gardens supply all the fresh vegetables required, and during the past few years a vigorous canning industry has developed and export markets are being supplied. During the season 1953–54, 16,000 tons of canned and quick-frozen vegetables were produced in addition to pulped products such as vegetable soups and tomatoes, and the annual export value of canned vegetables is now about £350,000.

Another product of the soil that is assuming considerable importance is softwood from the 1 million acres of exotic forests, mainly pines, of which nearly 50 per cent. are state-owned. The annual output of sawn timber from the softwood forests is nearly 300 million board feet, of which about 10 per cent. is exported. With development of the manufacture of wood pulp and paper, greater quantities of the timber will be used. The production of wood pulp in the Dominion for the year ending 31 March 1955 was 72,800 tons, of which 19,600 tons were exported.

A reasonable method of obtaining an indication of the relative importance of the several segments of production in New Zealand is to compare the values of their products. Table 1 shows clearly how important to the Dominion is the produce of its soil.

TABLE 1

VALUE OF PRODUCTION IN NEW ZEALAND, 1953–54

Type of production	Value million £	
Arable crops	30·9	
Pastoral	180·2	
Dairying, poultry, bees	98·0	
Forestry	17·2	326·3
Mining	11·0	
Fisheries	2·1	
Factory *	130·5	
Building, miscellaneous	48·2	191·8
		518·1

* Excluding the processing of primary products included in other groups.

A review of past trends in production is a help in making an assessment of future trends. The index of the volume of farm production shows that over the 30-year period 1890–91 to 1920–21 it almost doubled, but the next doubling took only 15 years, being achieved by 1935–36. In the second period farmers began to use good seeds to establish pastures and also to use superphospate to topdress the pastures. In the 15-year period 1935–36 to 1950–51 the increase has been only 31 per cent., but during the war there were difficulties such as shortage of labour and farm requisites. Statistics since the end of the war show that the increase in production has averaged nearly 3 per cent. per annum, and it is generally held that an annual rate of increase between 2 and 3 per cent. should be expected for some years.

CONDITIONS ASSOCIATED WITH INCREASED PRODUCTION

Though one of the main means of expanding production lies in increasing on existing farms the acreage of good grassland and using it efficiently, other means are being exploited and some of them can be examined from the national point of view.

Development of Unimproved Land

It has been estimated that there are about 2·0 million acres of virgin land in the Dominion suitable for and capable of development into farming land. The greater part is in the North and South Auckland Districts. At present about 150,000 acres of land are being sown to pasture each year, of which 80,000 acres are being developed by private owners and the remainder by the Departments of Lands and Survey and Maori Affairs. There appears every prospect that development will continue at the same rate for some time.

The land development work of the Department of Lands and Survey is on a large scale. Some idea of its magnitude can be obtained from a record of the material requirements for one year's operation, which in a recent year amounted to 1100 tons of fencing wire, 384,000 fencing posts and battens, 776,000 feet of water piping, 620 tons of grass seed, 32,000 tons of superphosphate, and 25,000 tons of lime. Large numbers of stock are carried on the blocks till these are subdivided and ready to be offered to settlers. At the end of June 1953 the Department had 390,000 sheep, nearly 6000 dairy cattle, and 67,000 store cattle, which certainly made it the biggest farmer in the Dominion. The land is developed for disposal to private farmers and 748 persons were settled between 1950 and 1953.

Aerial Topdressing

Topdressing is the basic answer to the improvement of about 13 million acres of the Dominion's hill country. Although before the advent of aerial topdressing some fertiliser was spread by hand, the work was laborious, expensive, and inefficient and therefore little was done to improve the unploughable hill pastures.

The first test of dropping fertiliser from the air was made in May 1939, but the war prevented further progress and it was not until 1946 that the first extensive experiments were made. Subsequent tests were made by the Royal New Zealand Air Force, and by 1949 it was shown that aerial topdressing was operationally possible. Since that time progress has been remarkable, as is shown in Table 2.

The part that aircraft are playing today is shown by the fact that slightly over 25 per cent. of the 1 million tons of superphosphate produced by fertiliser works in New Zealand in 1954–55 was distributed from the air.

The full results of the extension of aeral topdressing over the last five years have yet to be assessed and it may be difficult to arrive at any definite measure of the increased carrying capacity it has brought about. Some examples are, however, available to show the results achieved so far,

TABLE 2

Aerial Topdressing in New Zealand

Year ending 31 March	Weight of fertiliser distributed (tons)	Area treated (acres)
1950	5000	48,700
1951	45,000	428,700
1952	88,900	802,200
1953	144,800	1,376,100
1954	203,100	1,929,500
1955	279,000	2,783,800

and it is clear that substantial progress is being made on some hill areas. One example is of a hill property in the Marlborough Land District. The property covers 1740 acres of which 1560 acres are hill country rising from 600 feet to 3400 feet above sea level. The predominant cover on the hill area was danthonia and browntop and there had been no topdressing. In the 1949–50 season 1500 sheep were shorn, and in that season a start was made in topdressing a hill block of 160 acres with superphosphate from the air. Since then, except for 400 to 500 acres of the highest country, all the hill country has been topdressed and oversown with clover and grass seed from the air. In the 1954–55 season 2050 sheep were shorn and the average fleece weight had risen from 7·9 to 10·3 lb.

For aerial topdressing to be continued on the present scale, a continuation of high prices for meat and wool is probably necessary. On the other hand, aerial topdressing, by raising the productivity of hill country, has put some hill country farmers in a stronger financial position than ever before. It is claimed that much of the hill country which until now has carried only 1 ewe per acre may be able to carry about 3 ewes.

Irrigation

In the semi-arid area of Central Otago and on parts of the Canterbury Plains irrigation may eventually play a considerable part in increasing production. In Canterbury there are about 750,000 acres of land capable of being irrigated and in Otago about another 100,000 acres. At present irrigation water is available for some 10,000 acres in Canterbury, but many farmers have made little or no use of it. In Central Otago, where water is available for about 62,000 acres, it is fully used, but unfortunately in summer the water available is insufficient in some parts for effective irrigation.

The climate of Canterbury differs from that in most overseas countries where there are irrigation schemes in semi-arid areas. With an average rainfall of between 25 and 30 inches that is reasonably well distributed throughout the year, the climate

is not arid, but hot north-west winds prevail during summer, and the soils generally lack moisture-holding capacity, so that the effectiveness of the rainfall is reduced. The farmer bases his system of management on the stock he can carry during summer and does not wish to take the risk of carrying more.

The general re-organisation of farm management that irrigation would bring about would lead to some changes in the average size of holdings. To give the farmer a fair return under dry-land farming, holdings are about twice the size they would need to be if most of them were irrigated. A good deal of subdivision of holdings would follow the introduction of irrigation and consequently the land would support a larger population as well as produce more.

On the land capable of irrigation in Canterbury it has been estimated that with irrigation an additional million ewes could be carried, and in parts of Central Otago, carrying capacity could be increased from an average of 1 to 1½ ewes per acre to about 4. However, despite the present level of farm prosperity, many farmers in areas served by irrigation schemes, particularly in Canterbury, are unwilling to incur the considerable capital expenditure needed before water can be used. Some do not plan to use any water and others are content to irrigate only a small part of their farms. There are several reasons for their unwillingness, one of the most important being the extra labour that irrigation requires. On many farms no outside labour is regularly employed and on few is there more than one man. Extra labour means extra accommodation, which usually means a considerable capital outlay.

Chemical Weed-killers

Since the end of the war the importance of weed-killers in New Zealand agriculture has steadily increased; this is shown by the value of the materials imported for making weed-killing preparations, which increased from £88,000 in 1949 to £611,000 in 1954.

From the national point of view the control of weeds in pasture should eventually have a marked effect on the production of dairy products and meat, particularly from the areas of more intensive farming where "high fertility" weeds have been on the increase. The use of weed-killers also promises to bring into production areas of gorse-infested hill country, much of which has hitherto proved so intractable as to be almost worthless for farming.

Destruction of Rabbits

Rabbits were an early problem in New Zealand, for they became a serious pest in the early 1870s, when pastoralists were already finding that they had to reduce the number of stock they were carrying because of rabbits.

It is only since 1947 that a determined effort has been made to deal with the rabbit problem. In that year legislation was passed under which a Rabbit Destruction Council was set up as an advisory body to the Minister of Agriculture. Up to that time the trapping of rabbits for their skins was often profitable, but because a levy has been imposed on the rabbit skins sold in New Zealand and, recently, the export of rabbit carcases has been prohibited, the "farming" of rabbits is no longer lucrative and the policy now is to destroy by poisoning. The "killer" policy has been most effective. Areas, particularly in Otago, where rabbit infestation was severe, are now much relieved of the pest, and stock-carrying capacity is increasing as a result of the improved pasture. To assist in the work of destroying the rabbit the Government over the past five years has made available nearly £1·5 million to the Rabbit Destruction Council, which in turn makes grants to Rabbit Boards that apply the "killer" policy in the different districts.

Trace Elements

The correction of trace element deficiencies has already had an important economic effect in New Zealand. The discovery in the mid 1930s that cobalt deficiency was responsible for "bush-sickness", a wasting disease of stock widespread on some of the ash-shower soils in the central part of the North Island, enabled a large area of land previously of limited value to be developed for farming. In fact, until that time it was considered that the most suitable use for that land was the growing of *Pinus radiata* trees.

At present it can be claimed that if trace elements are arranged according to their immediate practical significance for agriculture, molybdenum is the most important one in New Zealand. Molybdenum deficiency in New Zealand soils was first demonstrated by Davies in 1945. By 1951 some outstanding field responses to molybdenum had been obtained in parts of Otago and Southland, and subsequent research has shown that some North Auckland soils also respond to treatment. Work is still proceeding in defining areas and conditions in which response to application of molybdenum may be expected, and a start has been made also in defining the soils on which application of molybdenum may give rise to pasture dangerous to stock.

The areas where response to molybdenum is obtained are fairly extensive and an increase in their productive capacity could make a significant contribution towards the expansion of national production.

PRODUCTION POTENTIAL BY DISTRICTS

To see the picture in greater detail it is necessary to consider potential production by districts. For the purpose of the present article, Land Districts have been chosen; these are land registration districts and not areas delineated by any physical characteristic such as climate, topography, or soil. The reason for choosing Land Districts is that agricultural and pastoral statistics can be compiled for those areas, but not for agricultural regions. The map shows the division of the Dominion into Land Districts.

The estimates of increase in livestock numbers for the next 30 years for each Land District were made by field officers of the Extension Division of the Department of Agriculture. To estimate the increases in livestock numbers they assessed the probable increase in carrying capacity of the different land classes within a county, which is a rural administrative area; the land classes usually comprised a group of soil types. Carrying capacity of the land classes was assessed in terms of livestock units, either the dairy cow in milk or the breeding ewe, and other stock was assessed in terms of those standards on the basis of relative feed intake.

Once a complete estimate for each county was compiled, the livestock units were split up into classes of livestock on the basis of the proportion of the classes in each county as shown by the agricultural and pastoral statistics for 1952. Groups of counties were then brought together to give estimates for Land Districts. The estimates are set out in Table 3. Present uses of the land and changes and extensions by which the increases estimated might be achieved are described below.

North Island

North Auckland

North Auckland has the distinction of being the cradle of farming in New Zealand, for it was at the Bay of Islands in 1819 that a beginning was made by missionaries to establish the first farm. In spite of this early start, parts of North Auckland, beyond the city of Auckland, can still be regarded as a pioneer fringe, because in considerable areas virgin land is still being brought into production. A land utilisation survey of the area made six years ago by the Department of Lands and Survey demonstrated this, by showing that of the farmable country nearly 1·3 million acres, about 40 per cent. of the total area of the district, were in an unimproved state.

The topography of the District is varied. In the southern part of the North Auckland peninsula there are low rolling downlands interrupted in

TABLE 3

Estimated Stock Numbers (Thousands) in New Zealand Land Districts in 1955 and 1985

Land District	Total sheep		Dairy cows in milk		Beef breeding cows and heifers		All other cattle	
	1955	1985	1955	1985	1955	1985	1955	1985

* The figures for total sheep for the several Land Districts were those for 1954, the latest available at the time of writing. For total sheep in New Zealand an estimate has been made of 39,000,000 for 1955.

places by moderately steep hills rising to from 600 to 700 feet above sea level; in the northern half the rolling areas are smaller, and moderately steep or steep hills predominate. Along a great stretch of the western coastline there are large accumulations of sand; loose rolling sand occupies about 60 square miles and rolling consolidated sand about 420 square miles. The climate is moist and warm, very few parts receiving less than 50 inches of rain per annum, but the distribution of the rainfall is not as good as in many other parts of the Dominion. The average fall in December, for instance, is about half that for the winter month of May. November, December, and January are usually months of low rainfall. The mean annual temperature at sea level is about 58° F. and the relative humidity is fairly high, about 80 per cent.

The general farming pattern is dairying on the alluvial soils in scattered valleys and plains, and intensive production of fat lambs together with dairying on the basic volcanic soils, the undulating limestone soils, and the undulating ploughable land. Semi-extensive and semi-intensive pastoral farming are practised on the higher unploughable country.

In the development of farming in the North Auckland District paspalum (*Paspalum dilatatum*), a subtropical grass which thrives particularly well because of the high rainfall and the mild climate, has been important. Under intensive grass farming paspalum has proved the ideal complement to ryegrass and white clover in the pasture sward, since the ryegrass comes away much earlier than the paspalum, which in turn provides most of the summer and autumn feed.

Citrus fruit is grown at Kerikeri on the east coast north of Whangarei, and of the annual New Zealand production of nearly 20,000 bushels of sweet oranges the North Auckland District produces about two-thirds. Grapefruit and lemons also are grown, as well as other subtropical fruits such as tree tomatoes and Chinese gooseberries.

Round Auckland city there is dairying for the whole-milk market and intensive market gardening; the latter is more common on the volcanic soils to the south of the city.

There are three large soil areas from which considerable increases in production are likely to be obtained. First the clay and loam gumlands, which occupy about 1000 square miles, occur in many places in the District and have developed under kauri (*Agathis australis*) forest, but were covered with low scrub and rushes when the first settlers arrived. They are strongly acid and well leached of plant foods, but considerable areas have been developed to support good pastures of ryegrass, white clover and paspalum, and the development is continuing. Production of nearly 200 lb. butterfat per acre or carrying of between 3 and 4 ewes per acre is possible on some of these soils.

In addition to the gumlands there are considerable areas of consolidated sand country to be brought into production and there the State has some plans for development. One of the last of the North Auckland soils to be tackled has been the type known as "ironstone country", a name derived from the formation of ironstone pellets in the basalt volcanic soils. There are about 50,000 to 60,000 acres of it and much of it can be worked by tractors. Development on a large scale began in 1949, when the Department of Lands and Survey grassed down a 500-acre block, which is now successfully carrying dairy stock, store cattle, and sheep. The development work is continuing, and it may be found possible to carry about $2\frac{1}{2}$ ewes and $\frac{1}{6}$ cattle beast per acre on a considerable part of this once "problem" country.

Though no allowance has been made for it in assessing the production potential of North Auckland, much land can be reclaimed from the sea when required. In the tidal harbours a great deal of the land between mean high-water and mean low-water marks could be reclaimed; an estimate puts the area at about 140,000 acres. The cost of reclamation would, of course, be great and in present conditions the work is not likely to be economic.

For some years North Auckland has been developing rapidly and over the past quarter of a century the area occupied for farming has increased from 2·8 to nearly 3·3 million acres.

Auckland

The District can be divided broadly into four topographical sections. The first is the western upland section extending inland from the west coast; it is hilly country with an annual rainfall between 60 and 100 inches. Further inland are the central lowland area of the Waikato, of which Hamilton is the principal town, and the Hauraki Plains. Here the annual rainfall is lower, 45 to 50 inches. To the east and south there is the pumice plateau, which has been built up by successive showers of pumice ash and is at an altitude of about 2000 feet, much of it reasonably flat with isolated volcanic cones rising from that level. The annual rainfall over much of the area is between 40 and 60 inches, but some higher areas have nearly 100 inches. The last section to the north-east, known as the Coromandel Peninsula, is steep country rising to 3000 feet, and much of it is unsuitable for farming.

On the western uplands sheep farming for the production of store sheep and wool is predominant, but much work is being done there to improve the hill pastures, and increasing numbers of fat lambs

and cattle are coming from these areas. The flat and easy rolling lands of the Waikato, the Hauraki Plains, and the narrow coastal plain of the Bay of Plenty on the east, form the chief dairying regions of the Dominion, with about 30 per cent. of New Zealand's two million dairy cows. All-grass farming is typical; the pastures grow for the greater part of the year, and the conversion of surplus early summer pasture into silage or hay provides the necessary supplementary feed in winter.

On the pumice plateau the Dominion's greatest undertaking in land development is in progress. Much of the pumice-covered area was "bush-sick," and until the discovery in the early 1930s that large areas were deficient in cobalt, the land was considered almost useless for farming. Not long before the second world war the Department of Lands and Survey began to develop some of the pumice plateau, but war-time shortages brought the work to a halt. Development work is now on such a scale that about 20,000 acres a year of this scrub-covered land are being sown to pasture, which enables between 60 and 80 new farmers to be settled each year.

The pumice plateau is also the site of the Dominion's largest exotic forests, which form the basis for the new papermaking industry. Here the Kaingaroa State Forest of 260,000 acres is one of the world's largest planted forests.

Gisborne

Except for a small area of plain round the town of Gisborne and some other small areas of flat land along river valleys, Gisborne District is hill country. The climate is mild, and the annual range of temperature is not great. The annual rainfall is about 45 inches on the coastal section, over 60 inches on the higher inland country, and above 100 inches along the mountain chain on the western boundary.

Extensive sheep farming is characteristic, and wool, surplus ewes, and wethers are the main products. It is estimated that the District supplies about 250,000 ewes and 100,000 wethers annually to other Districts of North Island.

On the hill country to the west, which occupies about 30 per cent. of the land area, there has been considerable erosion and reversion to secondary growth. On the farmed portion the carrying capacity is about 3/4 sheep and 1/8 cattle beast per acre. Yet, with the use of the aeroplane for oversowing and topdressing, there is a brighter future for some of the country, and there is likely to be a considerable increase in stock-carrying capacity.

The easier hill country, which includes the coastal hill area, is good sheep country, with a carrying capacity of about 2 sheep and 1/10 cattle beast per acre. Hereford and Polled Angus are the main beef breeds. This country too suffers from erosion and reversion, but during recent years there has been a considerable increase in the amount of fertiliser used, and reversion is likely to be arrested; carrying capacity should improve over much of the area from the present rate of 2 sheep per acre to about 4 sheep per acre.

The small area of flat country round the town of Gisborne, with a rich alluvial soil, is an area of mixed farming, dairying, sheep farming for fat lambs, market gardening, and production of pasture seed, and each year about 3000 acres of maize are threshed, which is 75 per cent. of the Dominion acreage under maize.

The District has a population with one of the highest proportions of Maoris to Europeans in New Zealand; about 45 per cent. of the rural population are Maoris. The Maori Affairs Department is encouraging them to farm their lands, and young Maori farmers are being trained in farming methods. In time, such a development must have a considerable influence on production in the District.

Hawkes Bay

Most of the District consists of hilly and steep country with smaller areas of flat land. From the western boundary the ranges and foothills extend for a considerable distance into the District, and take up about 50 per cent. of its land area of 3,250,000 acres. Running parallel to the ranges and extending from Napier to the southern part of the District is a valley lowland, the northern part of which is the Heretaunga Plain of 85,000 acres, the largest area of flat land in Hawkes Bay. To the east there is the coastal hill country, which is regarded as some of the best of the Dominion's hill sheep country.

Rainfall over most of the hill country is about 40 inches per annum, with higher falls against the western ranges. The northern and central part of the lowland area has one of the lowest rainfalls in the North Island, less than 35 inches per annum.

Sheep dominate the farming. The 2,760,000 acres occupied for farming carry about 4,800,000 sheep and 527,000 head of cattle, of which 54,000 are dairy cows in milk. In addition, there are about 7000 acres of orchards and market gardens, about 7000 acres growing cash crops, and each year between 8000 and 10,000 acres are set aside to produce pasture seed.

The orchards, which occupy 3800 acres, are situated on the Heretaunga Plain, about 12 miles south of Napier. Of the Dominion acreage of stone fruits, 36 per cent. is on the Heretaunga Plain, and 17 per cent. of the apple acreage. The production of apples per acre is the highest in New Zealand. The abundance of sunshine, on the

average 2400 hours per annum, and the low relative humidity contribute to make the region suitable for orchards.

The principal dairying region is in the south, in the valley lowland, where the rainfall is between 45 and 50 inches per annum.

It is to the hill country that the District must look for most of its increases in production. There are about 340,000 acres in the hill country section that are still in scrub, fern and second growth, and with modern equipment much of it could be developed. There are also 330,000 acres still under natural danthonia, much of it in the coastal hill country. In recent years a considerable amount of development work has been done and there are places where carrying capacity has been increased from 1½ to over 3 ewes per acre.

Taranaki

The region of Taranaki surrounding the extinct volcanic cone of Mt. Egmont (8260 feet) produces about 50 per cent. of the Dominion's cheese. Here the rainfall is well distributed and ranges from 50 inches on the coast to 80 inches nearer the mountain.

The northern, eastern, and south-eastern parts of the District form an upland which, though of relatively low altitude, is very rugged, and there are still large areas of bush. The rainfall over most of the upland is between 70 and 100 inches per annum. The first settlers felled the bush, burned it, and sowed grass seed on the ash. Rapid reversion to second growth, aided by the high rainfall, forced many of them to retreat, and it is only during the past decade that a vigorous attempt has again been made to develop some of the country. With bulldozers to construct tracks, heavy tractors to cultivate the easier country, and aircraft to oversow and topdress the steeper parts, it has been possible to reclaim many areas, and the work is continuing. Much of the upland region is capable of carrying sheep and cattle, and it is an area on which Taranaki will have to rely for a considerable part of the increase in production which must come from the District.

The number of dairy cows has increased by about 18 per cent. to 260,000 over the 10 years to 1955; this has been achieved mainly through more intensive farming on the dairying areas settled earlier. On the other hand, the number of sheep increased by nearly 22 per cent., to 1,150,000, during the same period; but the increase is due largely to development of some of the reverted hill country.

Wellington

Wellington is the largest of the North Island Land Districts and is divided into distinct western and eastern regions by a mountain range running in a north-easterly direction from the south coast.

In the western region from about 20 miles north of the city of Wellington there is an area of flat land which extends northwards for about 80 miles, where it emerges into rolling country and then into higher and more broken country. In the eastern region immediately east of the mountain chain is a lowland area, in the south of which is the Wairarapa Plain and, farther to the north, rolling or more hilly country. To the east of the lowland there is a large area of hill country.

Except for an area in the north-west and another in the north-east where the annual rainfall is below 40 inches, most of the farming areas have between 40 and 50 inches per annum; a few parts, particularly near the central mountain range, have over 60 inches.

Naturally, the farming pattern is varied. On the plain along the west coast farming is mostly for dairy produce and fat lambs, except for some market gardens which serve the city of Wellington and Palmerston North. On some of the rolling country immediately north of the plain there is a little cereal cropping in addition to sheep farming for fat lambs, and about 20 per cent. of the North Island wheat acreage is to be found here. On the hill country to the north-west there has been much reversion to fern and manuka, and farms have had to be abandoned, but during the past five years attempts have been made to re-develop some of the reverted country by modern techniques.

In the eastern region, on the plain and lowland area, dairying and fat lamb production are typical, and on the hill country towards the east coast, sheep farming for wool and store sheep. The plains and easy rolling country of the eastern section were the first in the Wellington District to be settled, and surveys of farm management made by the Department of Agriculture show that in many places production per acre is not as high as it could be if better methods of management were adopted. Any great increase of production appears unlikely until many of the farms pass into the hands of younger farmers.

The main area from which the District must look for increasing the number of livestock is the east-coast hill country. The area suffers at times from summer drought, but farmers who have cleared manuka-infested country and established good pastures have increased the carrying capacity from the equivalent of 1½ ewes to 3½ ewes per acre. If prices for meat and wool continue at the present levels, development work is likely to continue. Large areas of country too steep to be cultivated by implements are being oversown with subterranean and white clovers and topdressed with superphosphate from the air.

Another area where production is increasing is along the belt of sand dune country which occupies about 250,000 acres on the west coast. In the

past 25 years considerable progress has been made in developing the sand dune belt by applying phosphates and lime and by growing subterranean and strawberry clover.

South Island

Marlborough

Except for the Wairau Plain and river valley running inland from the coast near Blenheim and some other smaller areas of flat land on the coast and along river valleys, the Marlborough District is hilly and mountainous. Of the 2,400,000 acres occupied for farming, no less than 90 per cent. is too steep to be cultivated by implements. As a result most of the District is devoted to sheep. On the higher hill country the main breeds are Merino, with halfbreds, and Corriedale, and the main source of revenue for the farmers occupying the land is the sale of fine wool. On the lower hill country the sale of surplus sheep provides appreciable supplementary income.

On the flat areas and easy rolling country in and round the Wairau Valley there is mixed farming. Sheep are reared for the production of fat lambs and there is some dairying, cereal cropping (wheat and barley), and production of pasture seed. The Wairau Valley is one of the Dominion's chief pea-producing areas; about 5000 acres are harvested for seed each year. The climate of the area is suitable for cropping; the annual rainfall is about 25 inches, and the summers are hot and dry, so that suitable conditions exist for harvesting.

On the coast about 70 miles south of Blenheim in the Kaikoura district there is a small plain where dairy farming is carried on, the rainfall being over 40 inches per annum. The area can support good pastures of ryegrass and white clover.

The Marlborough District has been settled for just over a century, but for some years there has been little change in stock numbers. Sheep have remained at about 1,100,000 for the past 40 years, but there has been a gradual increase in the number of cattle other than dairy cows in milk, which has been accelerated recently. In 1920 there were 30,000 cattle, by 1950 the number had reached 44,000, and the latest return (1955) sets the total at 55,300.

In future the main stock increases in Marlborough are likely to occur on the hill country as a result of oversowing and topdressing, which will be aided by aircraft.

Nelson

The total land area of the Nelson District is 4,300,000 acres, of which only 1,100,000 acres are occupied for farming, the remainder being high or mountainous country, much of which is over 3000 feet and can never be adapted for farming. Even those figures do not convey the true picture, since, of the land occupied for farming, 350,000 acres are in fern and scrub and 181,000 acres in standing forest. The main area of flat land is the Waimea Plain, which is roughly triangular and lies immediately south of the town of Nelson.

Rainfall varies considerably, according to topography and proximity to mountains lying in the path of rain-bearing winds. Less rain is recorded on the small areas of flat land, particularly where they are near the northern coast-line. Over the north-western part of the District rainfall is about 150 inches per annum, and on parts of the eastern portion about 70 inches. The town of Nelson has an average rainfall of 38 inches.

The main farming areas are the Waimea Plain and valleys running inland from the northern coastal section. Here farming is diversified and includes dairying, fat-lamb raising, fruit growing, tobacco growing and market gardening. The orchard areas occupy about 4000 acres and are situated on the slopes of the Moutere Hills, which fringe the coastline westwards from the town of Nelson for about 20 miles. Apple orchards, which predominate, occupy about 3200 acres.

The whole of New Zealand's tobacco crop is grown on the alluvial soils of river valleys in the northern section of Nelson District; the area yearly devoted to the purpose is usually about 3000 acres.

North and south of Westport on the south-western coastal section and in two other small valley areas in the south there is some dairying.

The main area in which increase in farm production may be hoped for is that known as the Moutere gravels, a vast deposit of gravels, silt, and sand covering about 360,000 acres. It stretches from about 40 miles inland from the town of Nelson to the northern coastline and has an average width of 12 miles. It is hilly and has been regarded as problem country, but during recent years some farmers with heavy crawler tractors and modern equipment have successfully developed several thousand acres into pasture capable of carrying between 3 and 4 ewes per acre. It is estimated that about 150,000 acres of it can be farmed. Also on the gravels, there have been established about 50,000 acres of pine forest, and the production of soft woods is becoming important.

Westland

Westland District is a narrow strip of land that borders the Tasman Sea along the west coast of the South Island and stretches inland for an average distance of 25 miles to the irregular line of the Southern Alps. It is a rugged region of

three levels, steep mountain ranges, terraces, and lower ranges, and a narrow coastal plain. Running north-east from Greymouth is the relatively flat Grey River valley.

Westland is one of the high-rainfall regions of the Dominion ; Greymouth has an average annual fall of 101 inches and precipitation increases inland towards the Alps and southwards, the south coastal section being in the belt with 150 to 200 inches rainfall.

The early development of Westland centred on gold, and for a period during the gold rushes of the 1860s the district held most of the country's population. Coal mining was subsequently developed ; this and the exploitation of the native forest are still the main activities of the District. Now it is realised that coal and forest are wasting assets, and for the last ten years more attention has been given to the possibilities of farming in the region. Recently a land utilisation survey to define the areas which can be converted to farming was begun.

Cattle alone are important, and nowhere else in New Zealand are sheep so unimportant. Dairying is found where the clearings are sufficiently extensive to support a small dairy factory, and elsewhere, especially in remote south Westland, beef cattle are raised. In future, because of the high rainfall, cattle are still likely to play the major part in Westland farming.

Of the 893,000 acres occupied for farming in the District (total area 3,830,000 acres), at least 80 per cent. is unimproved or semi-improved. From the semi-improved land will come the main increases of production in the immediate future. The virgin country is not likely to be broken in and settled for a number of years.

Canterbury

Canterbury falls into four topographical units.

Southern Alps and foothills

The rugged mountain chain of the Southern Alps, with a north-easterly trend, has many peaks of over 8000 feet. Numerous subsidiary ranges, some at right angles to the main divide and others parallel to it, are separated by deep valleys and broad basins. The distance from the main divide to the outer edge of the foothills to the east varies from 30 to 40 miles and of Canterbury's land area of 9,760,000 acres over 75 per cent. is high mountainous and hill country.

Downlands

Along almost the whole length of the foothills there stretches eastwards an area of down country which at either end of the district extends to the sea coast. In the northern downlands, undulating country alternates with steep hills.

Plains

Between the foothills and ranges to the west, the sea to the east, and the lowlands to the north and south, lies the almost level expanse of the Canterbury Plains, which are about 120 miles long and have a maximum width of 40 miles. They are the largest flat area in the Dominion.

Banks Peninsula

Midway between the northern and southern boundaries of the district, Banks Peninsula rises abruptly from the eastern portion of the plains near the city of Christchurch. With one peak over 3000 feet, it is the remnant of a once large mass of volcanic rock formed principally by two volcanoes.

Compared with most other parts of New Zealand, the climate of much of Canterbury is considered dry. The rainfall is between 20 and 30 inches per annum on the plains, and increases westward, the mountainous country receiving over 50 inches.

The high country is the home of the run holders (see footnote, p. 556) who depend for their livelihood on the sale of fine wools from Merino and halfbred flocks. Holdings are large and carrying capacity is computed on the basis of acres per sheep, not sheep per acre. Many of the flocks contain more than 1000 sheep, and there are nearly 400 runs in the area with flocks of over 2500 sheep. In the winter the higher parts are under snow and the sheep are then moved to lower country. It is a part of New Zealand where little work has been done by the grassland scientist to select species suited to the environment, and until such a selection has been made there is not likely to be any noticeable increase in stock numbers. Even with such work, spectacular increases cannot be expected.

On the lower hill country sheep are farmed for wool and store sheep, and from this area come most of the ewes annually required for replacement on the mixed arable farms in the plains.

On the downlands and plains, cropping for cereals, pulses, potatoes, and pasture seeds together with the rearing of fat lambs is the most important type of farming. There are some dairy farms, mainly producing whole milk for the principal urban centres nearby. The Canterbury Plains grow per annum about 75,000 acres of wheat, 55,000 acres of barley, 16,000 acres of peas and 10,000 acres of potatoes ; about 100,000 acres are set aside each year for the production of pasture seed.

On the plains there are about 750,000 acres of soils with low moisture-holding capacity, and although improvements are being effected by the

introduction of subterranean clover and the use of lucerne, their ultimate productive capacity will not be attained until irrigation water becomes available. So far irrigation water is available for 100,000 acres, but irrigation schemes are costly and it is doubtful if any additions will be made for some years. It is evident, however, that consideration will eventually have to be given to the development of irrigation, since the carrying capacity of many of the soils of low moisture-holding capacity could be raised from the present level of between 1½ and 2 ewes per acre to 3 ewes and over.

With the improvements which are taking place on the downlands and foothill areas and also on the drier soils of the plains, future increases in stock numbers are likely to be considerable.

Otago

From high mountains on the fiords on the west coast, Otago stretches eastwards through a region of mountains and lakes to its central region of basins which lie between ranges of hills, the whole central section being almost surrounded by high mountains. From here hills extend to the coast in the east, and to the south they merge into downland. In the north-east coastal section there is a small plain extending inland along a river valley, and there is another plain in the lower Clutha river valley in the south-east. Also immediately south-west of Dunedin there is the Taieri Plain, from which Dunedin obtains much of its vegetables and milk.

Rainfall is high on the mountains on the extreme west, between 100 and 200 inches per annum, but it becomes rapidly less towards the east, and over the greater part of Otago the annual fall is between 20 and 40 inches. The central basins have the lowest rainfall in the Dominion; the annual fall does not reach 20 inches. Topography and climate have been conducive to extensive rather than to intensive farming, and sheep have dominated the farming scene. Of a total area of 8,100,000 acres occupied for farming no less than 6,600,000 acres are unimproved land, of which 5,100,000 acres are in natural tussock, the greatest area of tussock in the Dominion (approximately 45 per cent. of the total). Of the 1,500,000 acres of improved land, 1,300,000 acres are in pasture and the remainder is used for summer and winter fodder crops, some cereal crops, commercial orchards, and market gardens.

From 1930 until recently there was little change in stock numbers; sheep have remained at about 4 million and cattle, with the exclusion of dairy cows in milk, at about 110,000. Over the past four years, however, there has been an upward movement in the numbers of both sheep and cattle, and with the amount of development of private land that is occurring in some parts of the District the same trend should continue.

Along the hill country to the east some farmers have been ploughing up tussock areas and sowing good pastures of ryegrass and white clover. There has been a similar development also on the downlands in the south, where the browntop cover is being replaced by good pasture. The downlands area occupies nearly 240,000 acres and recent estimates made by economists of the Department of Agriculture show that sheep numbers there should increase by 25 per cent. in the next 10 years.

In central Otago, in the low rainfall region, for a number of years rabbits depleted the natural tussock cover and large areas became useless for farming. As a result of the policy of rabbit extermination, there has been a considerable improvement recently in the vegetative cover, which is being reflected in increased carrying capacity that will become still more evident in the future. In the basins of the central Otago region, where water is applied and good pasture species are sown, dramatic results are obtained without the application of lime or fertilisers. Land which without water will not carry 1½ sheep per acre can be converted to pasture capable of supporting 3 or 4. At present there are 15 irrigation schemes in the district serving 62,000 acres, and though there are a number of other areas where irrigation can be developed, it is doubtful if there will be any great extension of irrigation in central Otago for some years, because of the high capital cost of construction. Some of the irrigation schemes serve orchard areas also; there are about 3000 acres of peaches, apricots, and nectarines.

Southland

Of the South Island Land Districts, Southland is the one which during the past 35 years has shown the most vigour. In that time sheep have increased from 1,600,000 to 4,250,000, and in the last four years the average annual increase has been about 150,000. In the same period dairy cows increased from about 56,000 to a peak of 82,000 in the mid-1930s. Today they number about 42,000. The decrease is due to replacement of cows by sheep as drainage was extended and pastures improved.

The western portion, including the greater part of the South Island fiordland, will never be of any significance for farming. The remainder of the District, of which 3,200,000 acres are occupied for farming, consists of plains, downland, and hill country, and the topography of about half is such that it can be cultivated by implements. The main hill areas are in the west and south-east, with other isolated hill areas towards the north that break up the plains.

The south and south-eastern coastal parts have an average annual rainfall of from 45 to 50 inches, but northwards rainfall decreases to about 35 inches per annum. All the plains area is good country for fattening lambs and, with the development that is taking place on some of the eastern downland areas, where tussock country is being converted to good pastures, additional fat-lamb farms are being created.

In west Southland a large area of rolling and flat tussock country with an altitude between 700 and 1200 feet is being developed by the State. The Department of Lands and Survey has begun to break in 40,000 acres, which may represent the start of the development of nearly 200,000 acres of tussock country.

Of all the Land Districts, Southland is the one which is expected to record the greatest increase in sheep numbers during the next 30 years.

The total increases in stock numbers for the Dominion are given in Table 3 (p. 572). It is considered that such increases are possible when recent scientific and technical advances in agriculture have been taken into account and when allowance has been made for differences in the inherent ability of individual farmers.

SOME PROBLEMS

If the estimated increases of production are to be achieved, some problems will have to be overcome and there will also have to be a clear realisation of the farming industry's requirements. Some of the chief problems will now be considered.

Capital

The capital requirements will be considerable. On the better land, production can often be raised without any great increase of capital, but on the more difficult country outlay will be considerable. Where hill country is ploughed or giant-disked, cultivated, and sown to pasture the average cost at present is about £25 per acre. Where land is oversown and topdressed it is about £8 per acre. If scrub must be cleared before cultivation, the costs may be increased by from £3 to £5 per acre. In addition to the cost of establishing pasture, there is the cost of subdivision by fencing, water supplies, additional buildings and extra livestock and equipment.

Much of the capital will be found from farmers' own savings, and already farmers are encouraged by income tax concessions to use surplus earnings for certain classes of development work. Even so, considerable sums will have to come from other sources.

Under the normal policy of the institutions which provide short, medium and long term agricultural credit, the amount of the loan is based on the value of the security offered, and lending institutions usually require an adequate margin of security. It has not been their normal practice to lend money for development work and, in any event, those who want to develop unimproved country often have insufficient security to offer.

A significant step in the provision of finance for developing land was taken in 1950 when the Marginal Lands Act was passed. It introduced for the first time the principle that a government loan should be based on the potential value of a property rather than on its present-day value, and that advice and assistance should be provided for the borrower to enable him to develop the property. The board which was set up to administer the Act and consider applications for loans has placed considerable emphasis on the character of the prospective borrower and, where he has shown that he has the ability to develop his land to become an economic unit but is hindered by lack of capital, the board has usually made the necessary finance available. Unfortunately, the board has at its disposal each year less than £500,000, which means that it can make only a limited contribution to a national programme of land reclamation and development.

If the State is to expand its programme for developing Crown land and Maori-owned land, greater sums will have to be provided for the two Departments concerned, the Department of Lands and Survey and the Maori Affairs Department.

In addition to the farm capital necessary for land improvement and development, capital will be required for the processing and handling industries, for new fertiliser works, and for additional storage and port facilities.

Fertilisers

The provision of ample supplies of fertilisers will be a most important aid to increasing production.

At present about one million tons of phosphates, 35,000 tons of potash, and other fertilisers are used each year, and it has been estimated that by 1975 about two million tons of phosphates will be required. It is therefore obvious that additional fertiliser works will be necessary in areas that at present are at a considerable distance from existing works.

The expansion in the use of artificial fertilisers in recent years can be gauged from the statistics showing the area of grassland topdressed each year. In 1945, 1·6 million acres were topdressed; in 1954, 5·4 million acres.

Farm Machinery and Requisites

To improve soil fertility, establish better pastures, and use the pastures efficiently, mechanisation is a first essential. On ploughable country where pasture must be renewed, and that proviso applies to several million acres, the tractor is required, and on hill country where cultivation or oversowing, topdressing, and liming are initial requirements for improvement, the heavy crawler tractor and the aeroplane are now necessities. To use pastures efficiently, modern equipment for silage- and haymaking is required, including the tractor, forage harvester, buckrake, pick-up baler, and loader.

Some indication of how mechanisation on farms has increased is given by Table 4. It will be necessary for farm machinery to be readily available in the future, which means that farmers must have access to overseas equipment suited to local conditions.

TABLE 4

Machinery on Farms

Kind of machine	Numbers in :		
	1920	1940	1952
Milking machines . .	8,800	29,560	37,560
Internal combustion engines	13,980	23,350	29,050
Electric motors . . .	Not available	56,510	123,440
Shearing machines . .	5,160	10,630	20,810
Tractors	320	11,280	55,620*

* Figure for 1954.

With the increasing output of new types of farm machines, some of which are complex and expensive, the time has arrived when consideration should be given to the establishment of a station for testing many of the new machines in local conditions. Capital may be wasted if the farmer has to try some of the important equipment and then finds it not really suitable for the work for which it was bought.

At present, materials other than machinery are reasonably plentiful, but care will have to be taken that they continue to be available as required. Such foresight is needed particularly with building materials, fencing wire, piping, cement and chemicals. Temporary shortages of some of them can be exasperating to a farmer when he has embarked on a programme of land improvement.

Labour and Housing

As agricultural expansion takes place the demand for labour, both casual and permanent, will grow, but an increasingly large proportion of the labour on farms is likely to be contract and casual labour. It is difficult to foresee where this expanding labour force is likely to come from, because with the present shortage of labour in the Dominion there is little likelihood of attracting labour from the towns. Immigration policy could perhaps be so adapted as to help to meet the demand for farm labour.

In any case, it is desirable to improve the conditions for farm workers, which might help to retain labour on the land. In some of the more closely settled rural areas the scheme could be extended whereby State houses are built and let to farm workers who are obliged to work for a group of farmers. Under such schemes the workers' annual wages are guaranteed by the employer group, who also guarantee the rent to the State. In more isolated areas the application of such a scheme will seldom be possible and farmers there will have to provide accommodation for the additional workers needed.

In some areas, particularly in hill country districts where development work is in progress, the problem of obtaining and housing additional labour because the productive capacity of the farm has reached the limit which the owner can handle may prove a serious hindrance to attaining the possible increases in production. If a farm has reached the stage at which production can still be increased with extra labour but the farmer is unable or unwilling to employ and house the additional labour, then latent farming potential is left untapped.

There is also the need in some instances to raise the standard of existing farm homes, but fortunately New Zealand farmers generally appear to realise the benefits of a well equipped farmhouse. Few farm dwellings are without electricity and many farm kitchens are a source of envy to city housewives. It is a commonplace for them to be equipped with electric cookers, refrigerators and mixing appliances, in fact anything that will make the lot of the farm housewife easier. The telephone is to be found on almost all farms and even on back-country sheep stations there is the radio-telephone, which makes isolation more easily borne. All these amenities help to counteract the lure of the city for the country girl ; they also make for a more efficient and contented farm home, which in turn must have an indirect effect on the general efficiency of the farm.

It is estimated that in the past five years the 91,000 farmers in New Zealand have spent about £1½ million per annum on new farm dwellings and on modernising existing ones.

Scientific Work and Extension Services

For the production increases which have been achieved over the past 30 years New Zealand farmers would give a generous share of the credit

to the Dominion's agricultural scientists and the extension services of the Department of Agriculture, the Agricultural Colleges, and the New Zealand Dairy Board. The demands on these services will increase and research and extension tasks will become more complex. Agricultural scientific teams will have to be strengthened. The calibre of New Zealand's agricultural scientists is high, but may not remain so if the higher rewards offered by other Commonwealth countries, such as Australia, continue to attract some of the leading scientists from New Zealand.

Greater emphasis will have to be placed on agricultural extension services. Within the past five years a demand has arisen for more intensive aid, which is evident from the formation by farmers themselves of associations of about 50 who employ their own extension officer. There are now four such associations in New Zealand, and more will probably be formed soon. There will be a number of difficulties in operation, and the testing time for the farmers' associations will come when prices of farm produce move downwards.

Considerable difficulties are now being experienced in obtaining qualified staff for the extension services, and it is doubtful if a satisfactory State service can continue to be given unless there is a re-organisation of the services and a review of the rewards. Otherwise the prospects of attracting young people from secondary schools to the two Agricultural Colleges of the University of New Zealand to take degrees in agricultural science with the object of becoming extension officers are not good. The professional standing of extension services must be raised so that such a career becomes known as satisfying and rewarding.

Maori Land

There are about 4 million acres of Maori land in the Dominion, and although some of it is unsuitable, the Maoris are farming considerable areas of it. There are still large areas not being used or being poorly used.

Since the early 1930s the Maori Affairs Department has taken over areas where the Maori owners were agreeable and has developed the land, subdivided it, and allotted farm units to suitable Maori farmers, at the same time protecting the rights of the Maori owners. One of the difficulties has been to provide the Maori farmers with a lease on a satisfactory tenure and to protect them in respect of any improvements they may make on the farms. These problems are gradually being solved and, although production per acre is not high on most Maori farms, it is gradually improving and, as better conditions of tenure are devised, output will increase more rapidly.

At present the Maori Affairs Department is bringing into production about 11,000 acres per annum, of which about 75 per cent. is used for dairy farms and the rest for sheep farms.

There are many other problems, but those set out here are the principal ones. In his 1955 Annual Report to Parliament the Director-General of Agriculture summarised the position as follows: "The internal economy of New Zealand should be moulded on the recognition of the importance of primary industry to the national economy; and, so far as is expedient in the over-all economy, resources of labour, capital and goods should be directed to the development and servicing of our asset, the land of New Zealand, and to the production from that asset of purchasing power through the medium of sheep and cattle."

Information on the subjects discussed above will be found in the papers and reports listed below.

ANALYTICAL METHODS

General

2655

WIEGAND, O. F. and SCHRANK, A. R. **Concentration of solutes for paper chromatography.** *Anal. Chem.*, 1956, **28,** 259. [Dept. Zool., Univ. Texas, Austin 12.]

Three methods are described. The first consists in preparing a paraffin wax "dike" on the starting line of the chromatogram and applying the solution under investigation repeatedly to the enclosed area, evaporating after each application. In the second, a "wick" is prepared by evaporating the solution inside a suitably shaped "dike": the substance on the wick is then transferred by elution to the paper to be used for chromatography. In the third, a bent micropipette is used.

Carbohydrate Constituents

2659

DUBOIS, M., GILLES, K. A., HAMILTON, J. K., REBERS, P. A. and SMITH, F. **Colorimetric method for determination of sugars and related substances.** *Anal. Chem.*, 1956, **28,** 350–356. [Div. Biochem., Univ. Minnesota, St. Paul.]

The method depends on the colour reaction between phenol and concentrated H_2SO_4 and simple sugars, oligosaccharides, polysaccharides and their derivatives, including methyl esters, which contain a free or potentially free reducing group. The method is applicable to 2 ml. test solution containing from 10 to 70 μg. sugar. A yellow-orange colour is produced at 25° to 30° C. and the absorption is measured at 490 mμ. for

hexoses and 480 mμ. for pentoses and uronic acids. The method can be used with paper chromatography and is applicable to a wide range of material, including urine and blood.—H. G. Bray.

2660

LUDWIG, T. G. and GOLDBERG, H. J. V. **The anthrone method for the determination of carbohydrates in foods and in oral rinsing.** *J. Dent. Res.*, 1956, **35**, 90–94. [Eastman Dent. Dispensary, Rochester, N.Y.]

The anthrone method of Morris (Abst. 14, Vol. 18) was slightly modified. The sample of the solution or suspension of carbohydrate, obtained from some foods by grinding and heating in water at 100° C., was added to the anthrone reagent and heated at 100° C. for 5 to 10 min. and the carbohydrate was then estimated colorimetrically. The accuracy of the method, ± 10 per cent. for foods and oral rinsings, was greater than that given by other standard methods.—A. Hepburn.

ALCOCK, M. and CANNELL, J. S. **Temperature effects in the paper partition chromatography of sugars.** *Nature*, 1956, **177**, 327 – 328. [Thomas Kerfoot and Co., Ltd., Vale of Bardsley, Ashton-under-Lyne, Lancs.]

The R_F values of a number of sugars were measured over the temperature range 0° to 50° C. They were most affected by the water content of the developing solvent. If this increased with increasing temperature the R_F values increased, and if it decreased they also decreased.

H. G. Bray.

2663

GIOVANNOZZI-SERMANNI, G. **A new solvent for quantitative paper chromatography of sugars.** *Nature*, 1956, **177**, 586–587. [Lab. Biochem., Ist. Sci. Sper. Tabacchi, Via Nazionale 66, Rome.]

The mixture devised to separate sucrose, fructose and glucose consists of *n*-propanol : benzyl alcohol : water : 85 per cent. formic acid (50 : 72 : 20 : 20); in this solvent mixture the R_F values are sucrose 0·17, glucose 0·26, mannose 0·30, arabinose 0·32, fructose 0·32, xylose 0·33, ribose 0·41.

H. G. Bray.

2664

MOYA, F. and DEWAR, J. **A simple colorimetric method to determine sugar in urine.** *J. Lab. Clin. Med.*, 1956, **47**, 314–319. [Dept. Biochem., Victoria Gen. Hosp., Halifax, N.S.]

Benedict's qualitative reagent is added to urine and, in the filtered solution, the remaining cupric ion is estimated spectrophotometrically at 650 mμ. False positive results obtained in Benedict's qualitative test are discussed. The yellow-orange precipitate formed in such cases was found to contain urate; little or no cupric ion is removed from solution.—H. G. Bray.

POMA TRECCANI, C. and TENTORIO, G. Metodi di analisi per la determinazione separata dell' amido, di altri polisaccaridi e degli zuccheri solubili nei tessuti legnosi. [**Methods for separate estimation of starch, other polysaccharides and soluble sugars in woody tissues.**] *Ann. Sper. agrar.*, 1955, **9**, No. 6, Suppl., xxvii - xxxiv. [Staz. Sper. Ortofrutticolt., Milan.] English summary.

For estimation of the true starch in woody tissue of apple trees the material was dried at 70° C., milled and sieved to ensure a fine division and then extracted repeatedly with ethanol at 50° C. to extract all the simple sugars. The woody residue was suspended in boiling water and autoclaved at 120° C. for 1½ hr. After cooling at 40° C. some drops of dilute NaOH were added to bring the *p*H to 6. Enzymic hydrolysis followed with 9 ml. *M*/15 KH_2PO_4 and 1 ml. *M*/15 Na_2HPO_4, 2 ml. saturated NaCl solution and 5 ml. diastase solution, for 1 hr. at 40° C. The solution was then autoclaved again for ½ hr. to destroy the enzyme and cooled, and, after fresh addition of enzyme, incubated overnight. Next day it was again autoclaved, cooled and passed through a buchner filter. After a test with iodine to ensure that all starch had disappeared from both residue and filtrate, 50 ml. of the latter was shaken with 2 ml. basic lead acetate to obtain a clear solution in which the maltose could be titrated with $KMnO_4$ by the method of Bertrand. A table of constants is given from which the starch content of the sample can be calculated. Polysaccharides can be estimated in the buchner filtrate and soluble sugars in the ethanolic extract.—D. Duncan.

2674

FABRIS, A. and ALBONICO, F. Ricerche sulla determinazione della lignina nei foraggi. [**Estimation of lignin in forages.**] *Ann. Sper. agrar.*, 1955, **9**, 1131–1165. [Ist. Indust. Agrar. Univ. Naples, Portici.] English summary.

The methods of preparing lignin compared were those of Hägglund ("Hölzchemie", Akademische Verlagsgesellschaft, Leipzig, 1939), Zeisel (*Monatsh.*, 1885, **6**, 989), Noll and Hölder (*Papier-Fabr.*, 1931, **29**, 485) and Metha (*Biochem. J.*, 1925, **19**, 985). It is concluded that the method of Metha gives the purest lignin, but it also gives much less lignin than the method of Hägglund, and much less methoxyl.

Forages with a low lignin content usually had a low methoxyl content also. The physiological reasons for this need study.—D. Duncan.

Nitrogenous Constituents

2675

YOKOI, H. and AKASI, S. **An improved Kjeldahl-Nessler method.** *Nagoya Med. J.*, 1955, **3**, 91–104. [Dept. Biochem., Med. Sch., Nagoya City Univ.]

The sample is digested with a minimum amount of H_2SO_4 with the aid of H_2O_2 and copper selenite. This takes about 30 min. The digest is then neutralised with NaOH, with tropaeolin OO as indicator, and potassium mercuric iodide (Nessler's solution 1) is added. The resulting solution is incubated in a water-bath at 20° or 25° C. along with a similar tube containing *N* NaOH. After the contents of the tubes are mixed by continuous transfer and shaking, the final solution is left in the water-bath for about 15 min. to attain maximum colour development. The ammonia N, in amounts of 5 to 25 μg., is then estimated by spectrophotometer and in amounts of 25 to 130 μg. by an ordinary filter photometer. The percentage error of the method is 1·5 to 2·0 for most substances tried.—A. Hepburn.

2676

FISCHER, F. G. and BOHN, H. Eine Mikrobestimmung des Ammoniaks, insbesondere in Protein-Hydrolysaten. [**Micro-estimation of ammonia**

with special reference to protein hydrolysates.] *Hoppe-Seyler's Ztschr.*, 1955, **302**, 278–282. [Chem. Inst., Univ. Würzburg.] English summary.

This micro-diffusion method is applicable to 0·2 to 10·0 μg. ammonia in 30 to 100 μl. solution. The apparatus consists of a conical flask containing the solution being analysed and a glass cup containing the acid into which the ammonia is to diffuse, attached to a glass rod inserted into the stopper. A tablet of magnesium oxide and sodium chloride is added to the test solution and diffusion is allowed to proceed for 15 to 20 hr. The ammonia which diffuses into the acid is estimated by a ninhydrin method.—H. G. Bray.

2677

VÖGELI, H. Zur chemischen Trennung des Eiweiss- vom Nichteiweiss-stickstoff. [**Chemical separation of protein nitrogen and non-protein nitrogen.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag. Prof. Crasemann, 71–76. [Eidg. Landwirtsch. Versuchsanst., Zürich, Oerlikon.]

A comparison was made between precipitation techniques with copper hydroxide, trichloroacetic acid or tannin and extraction processes using alcohol, trichloroacetic acid or water.

PATON, J. B., ROBERTSON, G. K. and WELLBY, M. L. **Separation of proteins in biological fluids by paper electrophoresis.** *Med. J. Austral.*, 1954, i, 108–113. [Inst. Med. Vet. Sci., Adelaide.]

The separation of albumin and α_1-, α_2-, β- and γ-globulins in 25 μl. serum, on Whatman No. 3 MM paper, with the apparatus of Flynn and de Mayo (Abst. 3027, Vol. 21), veronal buffer *p*H 8·5, ionic strength 0·05 to 0·1, for 20 hr. at 135 volts or 16 hr. at 180 volts, is described. Strips were stained with bromophenol blue in ethanol saturated with mercuric chloride; the protein bands were cut out and eluted with 4 per cent. Na_2CO_3 solution in methanol, and the colour was measured photoelectrically and compared with standard curves. With the same method, alkaline phosphatase activity could be demonstrated in the α_2-globulin, and the concentration of cholesterol in the α_2-, β- and γ-globulin fractions could be measured.

Over 500 specimens of serum were examined and changes in the serum proteins during pregnancy and in some pathological conditions were studied.—M. H. Pierce.

2679

PETERSON, E. A. and SOBER, H. A. **Chromatography of proteins. 1. Cellulose ion-exchange absorbents.**

SOBER, H. A., GUTTER, F. J., WYCKOFF, M. M. and PETERSON, E. A. **2. Fractionation of serum protein on anion-exchange cellulose.** *J. Amer. Chem. Soc.*, 1956, **78**, 751–755; 756–763. [Lab. Biochem., Nat. Cancer Inst., Nat. Insts. Health, Bethesda, Md.]

1. An account is given of the preparation and physico-chemical properties of a series of new adsorbents from cellulose, containing carboxymethyl, diethylaminoethyl and phosphate groups and basic groups derived from triethanolamine bound to cellulose through reaction with epichlorohydrin. The last of these was less useful than the others for protein separation, but was valuable for the chromatography of nucleic acids. The first 3 adsorbents have high adsorptive capacities for proteins and elution can be achieved under mild conditions. Titration curves are given.

2. The use of a cellulose adsorbent containing diethylaminoethyl groups is described; *p*H and salt concentration gradients were used for elution. A loading of 170 mg. protein per g. adsorbent was practicable.—H. G. Bray.

2680

WUNDERLY, C. **Control of the staining procedure after paper electrophoresis.** *Nature*, 1956, **177**, 586. [Med. Clin., Univ. Zürich.]

A spot of polyetheneimine is applied to the paper after electrophoresis but before staining. This polymer is stained by naphthalene black and Sudan black and so can be used as a reference substance for both protein and lipoprotein staining.

H. G. Bray.

2681

MEJBAUM - KATZENELLENBOGEN, W. Turbidymetryczna mikrometoda oznaczania białek tanina. [**Turbidimetric micro-method for estimating protein by means of tannin.**] *Acta biochim. polon.*, 1955, **2**, 279–296. [Zakl. Chemii. Fizjol., Akad. Med., Wrocław.] Russian and English summaries.

For estimation of serum proteins, lysozyme and gelatine, a 10 per cent. solution of tannin in *N* HCl with 2 per cent. phenol was used. The method was turbidimetric, based on photocolorimetric measurements with a red filter. After incubation of the protein solution with the tannin reagent for 10 min. at 30° C., the degree of turbidity was stabilised with a protective colloid. The sensitivity of the tannin test depended on temperature, and its accuracy on the duration of incubation. A concentration of proteins suitable for the method should not exceed from 10 to 100 μg. in 4 ml. of the mixed sample and reagents. Within that range there was a linear relation between protein concentration and optical density. (From summary.)

2682

RIZZO, A. and GUZZETTA, F. Il metodo di Brandberg-Zaloziecki per la determinazione della protidemia totale serica. [**The method of Brandberg - Zaloziecki for estimating total serum proteins.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 381–383. [Ist. Clin. Pediat., Univ. Messina.]

The method of Brandberg-Zaloziecki with fuming HNO_3 was originally devised for measuring total protein in cerebrospinal fluid. Applied to the estimation of total protein in blood serum, it proved simple and precise. For 35 specimens of serum it gave a mean value 0·33 g. per cent. higher than that given by the Kjeldahl method, a difference attributed to the inevitable slight loss in the latter.

MÜLLER, R. and KRAMPITZ, G. Beiträge zur Aminosäurebestimmung in biologischem Material. 2. Methodisches und Vorversuche zur Chromatographie von Aminosäuren auf Ionenaustauschersäulen. [**Estimation of amino acids in biological material. 2. Technique and preliminary experiments on the chromatography of amino acids on ion-exchange columns.**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11,** 44–53. [Inst. Anat. Physiol. Haustiere, Univ. Bonn.] English summary.

For part 1 see Title 1416, Vol. 26.

2. The application of the technique of Moore and Stein (Abst. 4469, Vol. 21) is discussed and an automatic fraction collector is described.

H. G. Bray.

2695

GIRI, K. V. **Perchloric acid as reagent for tryptophan, tyrosine and hydroxyproline in paper chromatography.** *Naturwissenschaften*, 1956, **43,** 18. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

To detect tryptophan the chromatogram is run in *n*-butanol : acetic acid : water (4 : 1 : 5), dried and dipped in a mixture of 60 per cent. perchloric acid in absolute ethanol (1 : 5 v/v) and dried at 60° C. for 10 min. Tryptophan gives an intense yellow-green fluorescence in ultraviolet light : no other amino acid gives this reaction. To identify tyrosine and hydroxyproline the dried chromatogram is treated with 2 per cent. ninhydrin in acetone and dried at 60° C. for 10 min. before treatment with perchloric acid as above. Ninhydrin colours disappear or are replaced by pink or violet colours for all amino acids, except tyrosine and hydroxyproline, which give, respectively, yellow and brick-red colours in white light and brick-red and red-brown in ultraviolet light.

H. G. Bray.

2696

BARAUD, J. and GENEVOIS, L. Dosage iodométrique de la tyrosine, du tryptophan et de la méthionine dans les protéines solubles non hydrolysées. [**Iodimetric estimation of tyrosine, tryptophan and methionine in soluble non-hydrolysed proteins.**] *Bull. Soc. chim. France*, 1955, No. 11–12, 1499–1501. [Lab. Chim. Biol., Fac. Sci., Bordeaux.]

The method (Genevois and Baraud, *Chim. anal.*, 1955, 37) permits the estimation of tyrosine, tryptophan and methionine in about 2 hr. at 20° C. and was shown to be applicable to unhydrolysed soluble proteins. The results are comparable with those of other methods.—H. G. Bray.

2697

JANUS, J. W. **Determination of arginine.** *Nature*, 1956, **177,** 529. [Res. Lab., Kodak, Ltd., Wealdstone, Harrow.]

The substitution of oxines for α-naphthol in the Sakaguchi reaction as described by Macpherson (Abst. 3943, Vol. 16) is discussed.—H. G. Bray.

2698

KUK-MEIRI, S. and LICHTENSTEIN, N. **Colorimetric determination of glutamic acid in protein hydrolysates.** *Anal. chim. Acta*, 1956, **14,** 266–268. [Dept. Biol. Colloidal Chem., Hebrew Univ., Jerusalem.] French and German summaries.

Glutamic acid is removed from protein hydrolysates by adsorption on Amberlite IR–4B at *p*H 3 to 4 and elution with *N* HCl. Glutamic acid in the eluates is converted to the lactone of α-hydroxyglutaric acid, which is then converted to a hydroxamic acid by hydroxylamine. This acid is estimated colorimetrically with $FeCl_3$.

H. G. Bray.

2699

ARONSON, J. N. and ELVEHJEM, C. A. **The hydroxyproline content of animal tissues.** *Food Res.*, 1956, **21,** 109–111. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Hydroxyproline was estimated by a modification of the method of Troll and Cannan (Abst. 3854, Vol. 23). Proline and hydroxyproline react with ninhydrin in phosphate buffer to give a red pigment which is extracted with benzene. A comparison of the absorption of this solution, maximum for hydroxyproline 570 mμ., and

maximum for proline 550 mμ., allowed estimation of hydroxyproline.

Muscle from beef, veal, pork and lamb contained approximately 0·9 g. hydroxyproline per 16 g. N.

LISSITZKY, S. and LAURENT, G. Dosage de la leucine, de l'isoleucine, et de la phénylalanine de protéines par chromatographie sur papier. [**Estimation of leucine, *iso*leucine and phenylalanine in proteins by paper chromatography.**] *Bull. Soc. Chim. biol.*, 1955, **37**, 1177–1182. [Fac. Méd. Pharm., Marseilles.]

These amino acids are separated by chromatography of protein hydrolysates on paper, with *tert.*-amyl alcohol saturated with water in an atmosphere of diethylamine as solvent mixture. The spots are revealed by ninhydrin, marked, cut out and eluted as cadmium complexes and analysed by spectrophotometer.—H. G. Bray.

2701

PASIEKA, A. E. and MORGAN, J. F. **The identification of phenylalanine on paper chromatograms.** *Biochim. biophys. Acta*, 1956, **19**, 366–371. [Lab. Hyg., Dept. Nat. Health Welfare, Ottawa.] French and German summaries.

The method depends on the specific reaction of phenylalanine on paper with ninhydrin; spraying after heating with Hanks's modified Tyrode solution gives a deep blue spot.—H. G. Bray.

2702

FRIEDMAN, S., MCFARLANE, J. E., BHATTACHARYYA, P. K. and FRAENKEL, G. **Quantitative separation and identification of quaternary ammonium bases.** *Arch. Biochem. Biophys.*, 1955, **59**, 484–490. [Dept. Entomol., Univ. Illinois, Urbana.]

A resin (Dowex-50) column is used. The bases are eluted with *N* HCl and identified chromatographically, with methyl ethyl ketone : *iso*propanol : 0·1 *N* HCl (30 : 50 : 20) or *iso*propanol : pyridine : water (50 : 25 : 25) as solvent mixture, and detected by spraying with a 1 : 1 mixture of methyl orange and Congo red and then treating the paper successively with ammonia and HCl vapours. The method was applied to *dl*-carnitine and betaine hydrochlorides, creatinine and trimethylamine oxide.—H. G. Bray.

2703

THOMAS, A. J. and SHERRATT, H. S. A. **The isolation of nucleic acid fractions from plant leaves and their purine and pyrimidine composition.** *Biochem. J.*, 1956, **62**, 1–4. [Dept. Agric. Chem., Univ. Coll. N. Wales, Bangor.]

Mixed nucleic acids were extracted from leaves of sugar beet, bracken, clover, ryegrass and kale and from wheat germ. Pentose nucleic acid and deoxypentose nucleic acid fractions were separated by incubation with 0·3 *N* KOH, which made the second fraction precipitable with perchloric acid. The source of sample made little difference to the proportions of the different bases in the fractions. Deoxypentose nucleic acid had similar amounts of adenine and thymine, the most abundant bases, and a relatively high content of 5-methylcytosine.

A. Hepburn.

NICOLAJ, P. La determinazione dei grassi totali nelle feci del lattante. [**Estimation of total fats in the faeces of infants.**] *Boll. Soc. ital. Biol. sper.*, 1955, **31**, 591–592. [Clin. Pediat., Univ. Bologna.]

Gerber's milk butyrometer was used to measure fat in the faeces of infants. To 1 g. of faeces in the Gerber apparatus, 6 ml. distilled water was added, and the whole was well shaken; 1 ml. amyl alcohol and 14 ml. H_2SO_4 (density 1·82) were added and the mixture was shaken again and maintained at 37° C. for 12 hr., after which it was placed in a water-bath at from 80° to 90° C. By inversion and gentle agitation the fat was caused to rise into the narrow, graduated part of the apparatus where the amount could be read.

E. M. Hume.

2707

SAGER, O. S., SANDERS, G. P., NORMAN, G. H. and MIDDLETON, M. B. **A detergent test for the milk fat content of dairy products. 1. Milk cream and ice cream.** *J. Assoc. Off. Agric.*

Chem., 1955, **38**, 931–940. [E. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington 25, D.C.]

Fat was estimated in samples of milk, cream and ice-cream by an improved form of the BDI detergent method (Sager and Sanders, *Milk Ind. Found. Conv. Proc., Lab. Sec.*, 1952, **4**, 29). A solution containing sodium tetraphosphate, sodium bicarbonate and a detergent, either Triton X — 100 or Tergitol Dispersant NPX, is added to the sample in a Babcock bottle which is heated in boiling water with frequent shaking. After the addition of methanol, centrifuging and heating to 55° to 60° C. the column of fat is measured. Haziness of the fat column was prevented by the inclusion of bicarbonate. Fat values for milk and ice-cream agreed closely with those obtained by the Babcock and Roese Gottlieb methods and for cream were on the average about 0·75 and 1·0 per cent. higher than with those methods. The higher readings were due to a curved bottom meniscus, but if the bottles were treated with silicone the values obtained were the same as from the Babcock method and 0·25 per cent. higher than from the Roese Gottlieb method.—A. Hepburn.

2708

MECHAM, D. K. and MOHAMMAD, A. **Extraction of lipids from wheat products.** *Cereal Chem.*, 1955, **32**, 405–415. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 10, Calif.]

n-Butanol saturated with water was found effective for extracting lipids from ground whole wheat, flour, bran and gluten, though small amounts of non-lipid materials were also extracted. In contrast to other lipid solvents, butanol did not entirely destroy the cohesive properties of wheat proteins, so that glutens could be washed from extracted flours and glutens and wetted to form a "rubbery mass".—G. A. Garton.

2709

HARTMAN, L. **Analysis of technical monoglycerides with potassium periodate.** *Analyst*, 1956, **81**, 67–68. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

The sample is dissolved in a mixture of chloroform, pyridine and acetic acid and oxidised at ordinary temperature with a solution of potassium periodate in sulphuric and acetic acids. KI is added and the iodine liberated is estimated by titration with thiosulphate. Glycerol may be estimated with an aqueous solution of periodate.

FRANZKE, C. Bemerkungen über die jodometrischen Verfahren zur Bestimmung der Peroxydzahl in Nahrungsfetten. [**Iodimetric process for estimating the peroxide number of food fats.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103**, 108–112. [Inst. Lebensmittelchem., Humboldt Univ., Berlin.]

When the methods of Lea (Abst. 374, Vol. 1), Taüfel and Rothe (*Angew. Chem.*, 1949, **61**, 84), Hadorn and Jungkunz (Abst. 2749, Vol. 24) and Sully (*Analyst*, 1954, **79**, 86) were compared, those of Taüfel and Rothe and of Sully were found to be the most satisfactory. Modifications of these methods are described.—H. G. Bray.

2711

HENICK, A. S., BENCA, M. F. and MITCHELL, J. H. (Jr.). **Estimating carbonyl compounds in rancid fats and foods.** *J. Amer. Oil Chem. Soc.*, 1954, **31**, 88–91. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

The method depends on the formation of 2 : 4-dinitrophenylhydrazones of the carbonyl compounds in the presence of trichloroacetic acid as catalyst, and their colorimetric estimation in alkaline solution. The method is used to follow the artificially induced oxidation of maize oil, soya bean oil and lard.—G. A. Garton.

2712

GIBBLE, W. P., KURTZ, E. B. (Jr.) and KELLEY, A. E. **A semi-micro procedure for the separation and degradation of long-chain fatty acids.** *J. Amer. Oil Chem. Soc.*, 1956, **33**, 66–68. [Dept. Botany, Coll. Agric., Univ. Arizona, Tucson.]

The separation of radio-active fatty acids obtained from a culture of flax fruits *in vitro* in a solution containing acetate labelled with ^{14}C is described. The seeds are dried and extracted with light petroleum, the extract is saponified and the crude fatty acids are fractionated at low temperature. Unsaturated fatty acids are hydrogenated and saturated fatty acids degraded, the carboxyl group being removed and isolated as the carboxyl group of benzoic acid, which is separated by sublimation. The reaction proceeds by way of an alkyl phenyl ketone. The fatty acid containing one carbon atom less than the original is isolated and subjected to the same treatment, and so on until no more fatty acid can be recovered. Yields of from 70 to 75 per cent. fatty acid and benzoic acid can be obtained, so that at least 1 g. fatty acid is needed if 3 carbon atoms are to be degraded.—H. G. Bray.

2713

CORCORAN, G. B. **Chromatographic separation and determination of straight-chain saturated monocarboxylic acids C_1 through C_{10} and dicarboxylic acids C_{11} through C_{16}.** *Anal. Chem.*, 1956,

28, 168–171. [Res. Div., Armour and Co., Chicago 9, Ill.]

The stationary phase is 2 *M* aqueous glycine on silicic acid adjusted to the required *p*H with HCl or NaOH. The mobile phase used in gradient elution is *n*-butanol : chloroform. Three columns, *p*H 2, 8·4 and 10, are used for the separation of monocarboxylic acids from C_1 to C_{10} and two columns, *p*H 8·5 and 9, for dicarboxylic acids from C_{11} to C_{16}.—H. G. Bray.

2714

DESNUELLE, P. and BURNET, M. Comportement chromatographique des acides gras contenant une function oxygénée supplementaire dans leur chaîne. [**Chromatographic behaviour of fatty acids with an oxygen-containing group in their chain.**] *Bull. Soc. chim. France*, 1956, No. 2, 268–274. [Lab. Nat. Matières Grasses, Fac. Sci., Marseilles.]

Chromatography on silicic acid and silica gel and counter-current distribution are considered, but the method recommended is reversed-phase chromatography on rubber powder with light petroleum, b.p. 100° to 130° C., as stationary phase and 30 to 50 per cent. aqueous acetone as mobile phase. After elution the acids are estimated titrimetrically or gravimetrically. The acids studied were ricinoleic, lauric, myristic, palmitic, 12-hydroxy- and 12-keto-stearic and *trans*-9 : 10-dihydroxystearic acids.—H. G. Bray.

2715

DIETRICH, F. Zur Differenzierung der Lipoproteide des Serums mittels präparativer Elektrophoresemethoden. [**Differentiation of lipoproteins of serum by preparative electrophoresis.**] *Hoppe-Seyler's Ztschr.*, 1955, **302,** 227–235. [Med. Klin., Univ. Marburg a.d. Lahn.] English summary.

A column of alumina is used, with mixtures of light petroleum, b.p. 60° to 80° C., and ether as eluting solvents. Esterified and free cholesterol are estimated colorimetrically by means of Tschugaeff's reaction (acetyl chloride and zinc chloride) which was found to be more suitable than the Liebermann Burchard reaction.—H. G. Bray.

2716

DIECKERT, J. W. and REISER, R. **A paper chromatographic procedure for separating 1-mono-, 1, 3-di-, and triglycerides, cholesterol, and cholesteryl esters.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 123–126. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Lipids were applied singly or as mixtures to glass-fibre filter paper impregnated with silicic acid and the chromatogram was developed with 1, 2 or 3 per cent. ether in *iso*-octane as solvent. The position of lipids on the paper was located with a spray of 50 per cent. (v/v) aqueous H_2SO_4 ; the sprayed paper was warmed gently to reveal cholesterol-containing lipids as pink spots ; stronger heating revealed glycerides and sterols as brown-black spots.

In all the solvent systems the order of lipids on the chromatogram, from origin to solvent front, was : 1-monoglycerides, 1 : 3-diglycerides, cholesterol, triglycerides and cholesteryl esters. The R_F values of the glycerides were about the same whether the component fatty acids were saturated or unsaturated. Fatty acid chain-length did not affect the R_F value of the cholesteryl esters.

G. A. Garton.

SCHÖN, H. and GEY, F. Zur elutionschromatographischen Trennung des freien und veresterten Cholesterins in Organ- und Serumfetten und direkten kolorimetrischen Bestimmung. [**Chromatographic separation of free and esterified cholesterol in organ and serum fats and direct colorimetric estimation.**] *Hoppe-Seyler's Ztschr.*, 1956, **303,** 81–90. [Med. Forschungsanst., Max Planck Gesellsch., Göttingen.] English summary.

A modification of the method of Kunkel and Slater (*Proc. Soc. Exp. Biol. Med.*, 1952, **80,** 42 ; *J. Clin. Invest.*, 1952, **31,** 677), in which a starch medium is used. The procedure is applicable to 4 ml. serum. It is possible to estimate cholesterol, phospholipins and esterified fatty acids in the same extract.—H. G. Bray.

2718

RIKIMARU, M., TANAKA, Y. and HOSHINO, M. **Paper chromatography of phospholipids.** *Fukushima J. Med. Sci.*, 1955, **2,** 131–133. [Dept. Hyg., Fukushima Med. Coll.]

The separation of phospholipins by paper chromatography was investigated, with several solvent systems, *n*-butanol : dioxan (4 : 1), *n*-butanol : pyridine : water (5 : 3 : 1), *n*-butanol : acetic acid : water (4 : 1 : 2), *n*-butanol : glycerine : water (4 : 1 : 1), chloroform : ethanol : water (800 : 200 : 25), phenol : water (7 : 3), methanol, butyl acetate and acetone. The phospholipins included rice lysolecithin, egg yolk lecithin, lecithin and cephalin from human brain, commercial lecithin and the phospholipins of human placenta. The best separations were obtained with *n*-butanol : glycerine : water. Egg yolk lecithin gave 2 spots of R_F values 0·95 and 0·54 ; both reacted with phosphomolybdate but only the second with ninhydrin. Placenta phospholipins gave 4 spots of R_F values 0·91, 0·52, 0·43 and 0·37, all of which reacted with phosphomolybdate.—G. A. Garton.

2719

MARINETTI, G. V. and STOTZ, E. **Paper chromatographic separation of phospholipids.** *J. Amer. Chem. Soc.*, 1955, **77**, 6668–6670. [Dept. Biochem., Univ. Rochester, N.Y.]

The firm binding of phospholipins to paper is considered to be due to the positive charge on the nitrogen atom. This can be removed by acylation. With this technique complete chromatographic separation of phosphatidylcholines from phosphatidylethanolamines is possible in samples of 300 to 400 μg. Solvent mixtures used in ascending paper chromatography are lutidine : methanol (3 : 2), methanol : lutidine : acetic acid (4 : 16 : 1), and 2-octanol : lutidine : acetic acid (90 : 5 : 5). Phospholipins are detected by the formation of fluorescent compounds with Rhodamine B or G.

H. G. Bray.

BALIGA, B. S. and BASU, K. P. **Phospholipids in milk. 1. A method for the estimation of lecithin, cephalin and sphingomyelin in milk.** *Indian J. Dairy Sci.*, 1955, **8**, 119–128. [Indian Dairy Res. Inst., Bangalore.]

Lipids are extracted from 25 ml. milk with a 3 : 1 mixture of ethanol and ether and the solvents are removed under reduced pressure in an atmosphere of CO_2. The lipids, in solution in light petroleum, are then chromatographed on MgO (Abst. 2903, Vol. 14) in order to separate cephalins from choline-containing phospholipins. Lecithin P is then estimated after selective hydrolysis with mild alkali (Schmidt *et al.*, *J. Biol. Chem.*, 1946, **166**, 505), which does not affect sphingomyelin.

Thus total phospholipin P minus choline-containing phospholipin P gives cephalin P and the difference between choline-containing phospholipin P and lecithin P gives sphingomyelin P. The factors used to convert P content to phospholipin are: lecithin, 25·99; cephalin, 24·00; sphingomyelin, 26·83.—G. A. Garton.

2721

RADIN, N. S., LAVIN, F. B. and BROWN, J. R. **Determination of cerebrosides.** *J. Biol. Chem.*, 1955, **217**, 789–796. [Radioisotope Unit, Veterans Admin. Res. Hosp., Chicago, Ill.]

COLEMAN, D. L., WELLS, W. W. and BAUMANN, C. A. **Intestinal sterols. 2. Determination of coprostanol and certain related sterols.** *Arch. Biochem. Biophys.*, 1956, **60**, 412–418. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

For part 1 see Abst. 763, Vol. 26.

2. The mixed sterols are separated into 2 groups, (1) cholesterol, Δ^7-cholestenol, 7-dehydrocholesterol and cholestanol, (2) coprostanol and an unidentified sterol ("sterol D"), by chromatography on a silicic acid and celite column and the individual sterols are estimated by differential colorimetric analysis. Cholesterol, Δ^7-cholestenol and 7-dehydrocholesterol give colour maxima at different times with the modified Liebermann Burchard reagent. 7-Dehydrocholesterol gives an absorption maximum at 281·5 mμ. Cholestanol gives no colour and is estimated by difference, by a gravimetric digitonin method in conjunction with colorimetric analysis. The unknown component gives a red-purple colour with the reagent, which changes to blue in 3 min., and coprostanol a green colour which reaches maximum intensity in 80 min.

The average daily excretion, by adult male rats on a fat-free diet, of cholesterol, Δ^7-cholestenol, 7-dehydrocholesterol, cholestanol, "sterol D" and coprostanol was found to be 356, 538, 8·8, 164, 358 and 3210 μg., respectively.—H. G. Bray.

2723

HUMMEL, O. Zur Ergosterinbestimmung in Hefen. [**Estimation of ergosterol in yeasts.**] *Ztschr. Lebensmittel - Untersuch. Forsch.*, 1956, **103**, 190–198. [Zellstoff-fabrik Waldhof, Werk Mannheim.]

Colorimetric and gravimetric methods are discussed critically. An ultraviolet absorption method is recommended, the sterols being first precipitated as their digitonin complexes. The conditions necessary for rupturing the yeast cells vary with the strain of yeast and are discussed.—H. G. Bray.

DITTMANN, G. and CREMER, H. D. Chondroitinschwefelsäure in Knorpel, Knochen und Zähnen. [**Chondroitin sulphate in cartilage, bone and teeth.**] *Biochem. Ztschr.*, 1956, **327**, 368–376. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

A micro-method was devised for estimating chondroitin sulphate directly, instead of indirectly by way of hexosamine, by spotting the solution containing it on filter paper and developing with toluidine blue; the colour was measured by photometer and planimeter or, with greater accuracy, 1 per cent. for from 200 to 600 μg. in 0·03 ml., by colorimeter after elution of the spots. A similar method with gentian violet gave an accuracy of 3 per cent. for from 20 to 100 μg. in 0·03 ml. Agreement with the results calculated from estimation of hexosamine by a modification of the method of Einbinder and Schubert (*J. Biol. Chem.*, 1950, **185**, 725) was good for cartilage, which contained from 35 to 36 per cent. chondroitin sulphate, but not for bones and teeth, and

attempts to extract chondroitin sulphate more thoroughly from these failed. Methods for estimating inorganic and total sulphur were investigated also.—W. M. Deans.

2725

EGOROV, I. A. and BORISOVA, N. B. Razdelenie i kolichestvennoe opredelenie ketokislot v vine metodom raspredeletel'noi khromatografii na bumage. [**Separation and estimation of keto acids in wine by paper partition chromatography.**] *Dokl. Akad. Nauk SSSR*, 1955, **104**, 433–435. [Inst. Biokhim. A.N. Bakha, Akad. Nauk SSSR.]

The application of paper chromatography to wine is described. A typical chromatogram is given illustrating 2 forms of pyruvic acid, and ketoglutaric acid, which were identified by their absorption spectra. The amounts of these acids in different wines are tabulated.—D. W. Taylor.

2726

GROTT, J. V. Méthode de dosage de l'acide oxalique dans le plasma, le sérum et les globules rouges du sang. [**Estimation of oxalic acid in blood plasma, serum and red cells.**] *Acta gastro-enterol. belg.*, 1955, **18**, 772–778. [Acad. Méd., Łodz.] Flemish, English, German and Spanish summaries.

The sample is haemolysed if necessary and deproteinised with trichloroacetic acid and the oxalate is precipited as the calcium salt, which is separated by filtration. The precipitate is dissolved in HCl and the solution is treated with H_2SO_4, manganous sulphate and permanganate; the excess of the last is estimated iodimetrically.

H. G. Bray.

Inorganic Constituents

2727

SMEETS, W. T. G. M. **The determination of the concentration of calcium ions in milk ultrafiltrate.** *Nederlands Melk Zuiveltijdschr.*, 1955, **9**, 249–260. [Lab. Vet. Biochem., State Univ., Utrecht.] Dutch summary.

Four methods were investigated, namely, a method depending on the spreading of a unimolecular layer of stearic acid, a conductimetric titration method, a picrolonate method and a murexide method. The last of these was found to be most satisfactory. It consists in measuring the extinctions at 480 mμ. of the ultrafiltrate and standard solutions to which murexide has been added.

The average ionic Ca content of 40 milk ultrafiltrates was found to be 11 $\pm$ 1·6 and the total Ca 34·7 $\pm$ 4·9 mg. per cent. It is calculated that 35 per cent. of the Ca in the ultrafiltrate is ionic, 55 per cent. bound to citrate and 10 per cent. to phosphate. It is suggested that the "Utrecht abnormality" of milk, *i.e.*, a decreased stability of protein-bound Ca, so that the milk flocculates on boiling or even at ordinary temperature, may be due to an increased content of Ca ions, since it was shown that milk to which Ca ions have been added becomes unstable when the concentration exceeds 16 mg. per cent.—H. G. Bray.

2728

SMITH, A. M. and MCCALLUM, E. S. R. **The determination of calcium and magnesium in plant material with disodium ethylenediaminetetraacetate.** *Analyst*, 1956, **81**, 160–163. [Edinburgh and East of Scotland Coll. Agric., Edinburgh 8.]

The sample, 10 g., is dry-ashed and Fe, Mn and phosphate, which interfere with the estimation, are removed by precipitation. Ca and Mg are estimated together by titration with ethylenediamine tetra-acetate with Solochrome black as indicator, and Ca alone with murexide as indicator. Excess ammonium chloride affects the end-point with murexide and is removed by boiling the alkaline solution before titration.—H. G. Bray.

2729

HEMINGWAY, R. G. **The determination of calcium in plant material by flame photometry.** *Analyst*, 1956, **81**, 164–168. [Dept. Agric. Chem., Univ. Glasgow.]

Phosphates interfere with the method, which uses the EEL flame photometer, and are removed from a solution of the ash by the cation-exchange resin Amberlite IR–120 (H). Al, Fe, Mn, Mg and K in the concentrations found in plant material do not interfere. If Na is present in concentration equivalent to that of Ca its interference can be corrected for. The accuracy of the method is $\pm$ 2·2 per cent. and the results agree well with those of an oxalate method.—H. G. Bray.

2730

BÖHLER, K. Erfahrungen mit einer neuen Methode zur Bestimmung des Calciums im Serum. [**A new method for estimating serum calcium.**] *Schweiz. med. Wochenschr.*, 1956, **86**, 68–69. [Lab. Med. Abt., Stadtspital Waid, Zürich.]

Direct titration of calcium with Komplexon III, the disodium salt of ethylenediamine tetra-acetic acid, is described. The method, which depends on the formation of chelated compounds, was simpler, quicker and more accurate than titrating Ca as oxalate with permanganate.

Distribution of serum Ca values in 120 subjects showed a normal pattern with 95 per cent. of all values falling between 8·7 and 10·7 mg. per cent.

A. M. Copping.

2731

CARLSTRÖM, G. **Studies on parturient paresis in dairy cows. 2. Determination of calcium ions in bovine serum.** *Acta Agric. scand.*, 1955, **5**, 357–374. [Res. Stat. Vet. Inst., Skara, Sweden.]

For part 1, see Abst 5981, Vol. 25.

2. Serum is treated with an aqueous solution of murexide and the wavelength corresponding to maximum extinction and the *p*H are measured. The Ca content is found from a nomogram.

H. G. Bray.

RAMSAY, J. A., BROWN, R. H. J. and CROGHAN, P. C. **Electrometric titration of chloride in small volumes.** *J. Exp. Biol.*, 1955, **32**, 822–829. [Zool. Lab., Univ. Cambridge.]

Two methods applicable to biological fluids are described. The first is a titrimetric method with which 1 μg. chloride can be estimated in volumes down to 0·2 μl. In the second method silver ions are produced by passing a current through a silver electrode in series with a condenser on which a charge develops, which is a measure of the chloride titrated. This method is applicable to as little as 10^{-4} μg. chloride in volumes as small as $0{\cdot}5 \times 10^{-3}$ μl. The apparatus used is described in detail.

H. G. Bray.

CASTER, W. O., MACDONALD, R. and ARMSTRONG, W. D. **Methods for the determination of muscle chloride.** *J. Lab. Clin. Med.*, 1955, **46**, 910–913. [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

2734

KEENAN, R. G. and KOPP, J. F. **Spectrochemical determination of trace quantities of cobalt in animal tissues.** *Anal. Chem.*, 1956, **28**, 185–189. [Occupat. Health Field Headquarters, Pub. Health Serv., U.S. Dept. Health, Cincinnati, Ohio.]

Two spectrochemical methods were developed. The first is applicable to the soft tissues of animals containing at least 0·025 μg. Co per g. fresh tissue more than the normal amount. The material is ashed and Co is estimated directly. The second method is suitable for the estimation of Co in bone and in the tissues of normal animals. The tissue is ashed and Co is separated as its 1-nitroso-2-naphthol derivative; this in turn is ashed and the Co in the residue is estimated spectrographically.

H. G. Bray.

2735

KOCH, H. J. (Jr.) and SMITH, E. R. **The determination of copper and zinc in normal and pathologic human thyroid tissue.** *J. Clin. Endocrinol.*, 1956, **16**, 123–129. [Dept. Clin. Invest., Sloan-Kettering Inst., New York.]

Cu and Zn were estimated in tissue ash by a dithizone method and by arc spectrography: Zn was also estimated by neutron activation and separation on a column of Dowex-50 resin.

Values are given for the Zn and Cu content of human thyroid and other tissues.—H. G. Bray.

[**Estimation of the content of lead, tin, copper and zinc in meat and fish conserves.**] *Rocz. Państwowego Zakl. Hig.*, 1955, **6**, 277–288. Russian and English summaries.

2743

MANN, C. K. and YOE, J. H. **Spectrophotometric determination of magnesium with sodium 1-azo-2-hydroxy-3-(2, 4-dimethylcarboxanilido)-naphthalene-1′-(2-hydroxybenzene - 5 - sulfonate).** *Anal. Chem.*, 1956, **28**, 202–205. [Pratt Trace Analysis Lab., Dept. Chem., Univ. Virginia, Charlottesville.]

The test solution, made just acid to phenolphthalein and containing from 0·5 to 10 μg. Mg in up to 5 ml., is mixed with a solution of the reagent in 95 per cent. ethanol and 0·5 ml. of 0·08 *M* borax and diluted to 25 ml. with 95 per cent. ethanol. The absorption at 510 mμ. is measured after 30 min. Interference by other ions was studied.—H. G. Bray.

2744

SASSI, L. Sur le dosage du magnésium dans une eau potable. [**Estimation of magnesium in drinking water.**] *Arch. Inst. Pasteur Tunis*, 1955, **32**, 287–306. [Inst. Pasteur, Tunis.]

The difficulties of estimating Mg in drinking water when other ions are present which cause interference are discussed. Methods for eliminating these ions and precipitating Mg as the double iodide of Mg and hexamethylenetetramine are described.—E. M. Hume.

2745

STRZEMIEŃSKI, K. (with WILLIAMS, R. M.) **Total and radioactive phosphorus determination in small plant samples using the gravimetric method of Lorenz.** *N.Z. J. Sci. Technol.* [*B*], 1955, **37**, 243–257. [Soil Bur., D.S.I.R., Wellington.]

The gravimetric method used consists in the precipitation of ammonium phosphomolybdate in the presence of a large excess of reagents: this reduces interference by other constituents of soil, fertiliser and plants. The precipitate is washed with acetone, dried and weighed. Radio-activity is measured after conversion of phosphomolybdate to magnesium ammonium phosphate. In an appendix a method is given for the estimation of the technical error arising from experimental procedures as distinct from that due to random fluctuations in radio-activity.—H. G. Bray.

2746

RICKEY, G. F. and AVENS, A. W. **Photometric determination of total phosphorus in feeding stuffs and fertilizers.** *J. Assoc. Off. Agric. Chem.*, 1955, **38**, 898–903. [New York Agric. Exp. Stat., Cornell Univ., Geneva.]

Samples of feedingstuffs and fertilisers were digested with HNO_3 and perchloric acid, and total P was estimated spectrophotometrically after reaction with a vanadomolybdate mixed colour reagent. The method was accurate enough for routine analyses and took much less time than the A.O.A.C. method.—A. Hepburn.

2747

TANAKA, M. and KANAMORI, S. Une méthode de dosage colorimétrique du phosphore dans les matières organiques. [**A method for the colorimetric estimation of phosphorus in organic materials.**] *Anal. chim. Acta*, 1956, **14**, 263–265. [Lab. Chim. Anal., Inst. Chim., Fac. Sci., Nagoya Univ., Japan.] English and German summaries.

A new type of flask is described in which organic matter can be destroyed without bumping. Ferric chloride is included in the reagents used. After ashing, the digestion mixture is neutralised, the precipitate formed is dissolved in H_2SO_4 and phosphate is estimated in the solution by a molybdate method. The procedure is applicable also to natural waters.—H. G. Bray.

2748

FLASCHKA, H. and HOLASEK, A. Über die komplexometrische Bestimmung des Kaliums im Blutserum. [**Complexometric estimation of potassium in blood serum.**] *Hoppe-Seyler's Ztschr.*, 1956, **303**, 9–13. [Med. Chem. Inst., Univ. Graz.] English summary.

Potassium is precipitated from 1 ml. serum by a reagent containing sodium nitrite, cobalt nitrate and acetic acid and the precipitate is separated by centrifuge. The washed precipitate is treated with HCl and urea in a boiling-water bath, ammonia and murexide are added and the solution is titrated with disodium ethylenediaminetetra-acetate. The maximum variation of the results was found to be 0·7 mg. per cent. and the mean error 0·2 mg. per cent.—H. G. Bray.

2749

NEWFIELD, O. E. and TILSON, F. A. **The determination of sodium and potassium in the "Beckman model DU" flame spectrophotometer.** *Med. J. Austral.*, 1955, i, 751–752. [Repatriation Gen. Hosp., Heidelberg West, Victoria.]

A Beckman Model DU quartz spectrophotometer and flame attachment, supplied with an all-metal palladium-tipped injection system, gave high values for serum K and low values for serum Na when compared with results obtained by a modification of Abul-Fadl's chemical method (Abst. 1742, Vol. 19; Neufeld, Abst. 120, Vol. 22). No improvement resulted from preliminary precipitation of the serum protein, but a 1 in 50 dilution of the serum and standards with a lithium chloride solution, made from 26·617 g. lithium carbonate per 1000 ml. and diluted 1 in 250, gave excellent results at wavelength 767 mμ. and slit width 0·2 mm., the 20 mg. per 100 ml. standard being set at 50 per cent. transmission. For estimating Na the use of a standard closely approaching the concentration in the serum under study was necessary.—M. H. Pierce.

MICROBIOLOGICAL

2763

HORN, M. J. and BLUM, A. E. **A microbiological method for determination of cystine in foods.** *Cereal Chem.*, 1956, **33,** 18–28. [Human Nutrit. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington 25, D.C.]

The organism used was *Leuconostoc mesenteroides* P-60 and the basal medium contained as amino acid source an acid hydrolysate of "lanthionised" casein, *i.e.*, casein boiled with 2 per cent. sodium carbonate to convert cystine to lanthionine, plus added tryptophan and arginine. Values are given for the cystine content of 60 proteins and foodstuffs.—H. G. Bray.

2764

RUEBNER, B. **The biologic assay of L-methionine using a mutant of Bact. coli strain K-12.** *J. Lab. Clin. Med.*, 1956, **47,** 140–144. [Dept. Pathol., Postgrad. Med. Sch., London.]

L-Methionine was estimated in protein - free plasma by measuring turbidimetrically the growth of a mutant of *Bacterium coli* and comparing it with a standard curve. Methionine was essential for the mutant and could not be replaced, except by cystathionine or homocysteine. These were apparently not present in amounts sufficient to affect the assay, as similar results were obtained with another mutant which required both methionine and proline and could not utilise cystathionine or homocysteine in place of methionine.

The method was used to study abnormal methionine metabolism in patients with cirrhosis of the liver.—A. Hepburn.

DONOVAN, P. B. and TIGHE, W. J. **A quantitative modification of the "tubeless" gastric analysis.** *J. Lab. Clin. Med.*, 1955, **46,** 895–899. [Clin. Res. Lab., Rees-Stealy Clin., San Diego, Calif.]

A resin, Amberlite XE–96, in which the exchangeable hydrogen ions are replaced by quinium radicals, is swallowed and the free HCl of the gastric juice displaces the quinium ions, which form quinine hydrochloride. This is rapidly absorbed and excreted, so that the urinary excretion is a measure of the acidity of the gastric juice. In 101 patients a simple quantitative correlation was found between 2-hr. urinary excretion of quinine and the results of conventional gastric analysis.

H. G. Bray.

MCFARLANE, A. S. **Labelling of plasma proteins with radioactive iodine.** *Biochem. J.*, 1956, **62**, 135–143. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

Four methods of iodinating plasma proteins are described: (1) iodine is liberated from iodide by H_2O_2 in the presence of protein at *p*H 7; (2) free iodine in KI is mixed with the protein in a bicarbonate buffer at *p*H 9·5 to 10·0; (3) a mixture of iodide and iodate is acidified and added to an ammoniacal solution of the protein; (4) a jet injection of free iodine is made into the protein dissolved in a glycine buffer at *p*H 9·3, and excess iodine is removed by ion exchange.

The labelled proteins produced are in general eliminated more rapidly by the rabbit than ^{14}C-labelled plasma proteins, especially if 6 or more atoms of iodine per molecule of protein are present. A method is described for substituting 0·5 atom iodine per molecule so that the labelled albumin and globulin behave in the rabbit in a way comparable to that of ^{14}C-labelled protein.

H. G. Bray.

WILLEBRANDS, A. F. and GROEN, J. Verdere ervaringen met de bepaling van insuline in bloedserum met behulp van het geïsoleerde rattediafragma. [**Further studies on the estimation of insulin in blood serum with the isolated rat diaphragm.**] *Nederland. Tijdschr. Geneesk.*, 1956, **100**, 817–823. [2. Klin. Inw. Ziekten, Wilhelmina Gasthuis, Amsterdam.] English summary.

For previous work see Title 5515, Vol. 20.

For each test the diaphragms of 8 rats that have fasted for 24 hr. are used. Four flasks are set up and incubated, each with one-quarter of each of the 8 diaphragms, buffer solution and glucose alone, or with insulin in a concentration of 10^{-4} or 10^{-3} unit per ml., or with the serum to be tested. Disappearance of glucose per 100 ml. diaphragm is the measure of insulin present. The method is not sensitive but will demonstrate gross departures from normal.—I. Leitch.

2781

WELLINGTON, G. H., REID, J. T., BRATZLER, L. J. and MILLER, J. I. **Use of antipyrine in nutritional and meats studies with cattle.** *J. Animal Sci.*, 1956, **15**, 76–85. [Cornell Univ., Ithaca, N.Y.]

Holstein cattle of both sexes were fed on low, medium or high planes of nutrition from birth until slaughter at 16, 48, 64 or 80 weeks of age. Close agreement was found between values for total body water estimated by the degree of dilution of a known quantity of antipyrine injected intravenously, and by estimation of moisture in all the body tissues. For 20 animals of different ages and degrees of fatness the average difference between the methods was 0·48 per cent.; the correlation coefficient was 0·939.—T. R. Preston.

SCHAMBYE, P. **Experimental estimation of the portal vein blood flow in sheep. 1. Examination of an infusion method and results from acute experiments. 2. Chronic experiments in cannulated sheep applying infusion and injection methods.** *Nord. Vet.-Med.*, 1955, **7**, 961–973; addendum 974–975; 1001–1016. [Dept. Special Pathol. Therap., Royal Vet. Agric. Coll., Copenhagen.] German and Dutch summaries.

1. The procedure described is based on the indicator-dilution principle. Blood labelled with ^{32}P (erythrocytes) or the dye T 1824 (plasma) was infused into the peripheral branch of the portal vein and samples of carotid and portal blood were taken for estimation. The underlying theory is discussed in detail. Values are given for the average portal flow in acute experiments on sheep, calves and goats.—H. G. Bray.

2. Ewes were prepared by stitching a London cannula to the portal vein and exteriorising the left carotid artery. A polythene tube was inserted into a peripheral branch of the mesenteric vein. Cardiac output and circulating blood volume could then be estimated without anaesthesia by injection of T 1824 into the jugular vein, portal flow by injection of T 1824 into the mesenteric vein or by infusion of blood containing either T 1824 or red cells labelled with ^{32}P or both.

Values for portal flow when both indicators were used together were closely similar. The mean value for 5 sheep was 37·1 and the range 31·1 to 43·9 ml. per min. per kg. bodyweight, or about 26 per cent. more than in the acute experiments described in part 1. The mean portal flow could also be expressed as 266 ml. per min. per 100 g. liver. The portal flow made up from 26 to 40 per cent. of the total cardiac output, in one experiment 52 per cent. The results of injection experiments were more variable than those obtained by infusion, but close agreement was sometimes shown.

The mean circulation time from peripheral portal vein to carotid artery was 24 to 28 sec., and that from carotid to portal main trunk 12 sec., giving a mean circulation time from portal vein to heart to lungs to heart to aorta to portal vein of 40 sec., and a mean time for portal vein through liver to heart of 15 sec.

The value of 37 ml. per min. per kg. bodyweight for portal flow is thought to be the closest approximation so far obtained for sheep.—D. Duncan.

2783

BECKER, E. L. and JOSEPH, B. J. **Measurement of extracellular fluid volumes in normal dogs.** *Amer. J. Physiol.*, 1955, **183**, 314–316. [Dept. Int. Med., U.S. Air Force Sch. Aviation Med., Randolph Air Force Base, Tex.]

The volume of extracellular fluid was measured in 10 normal, adult, female mongrel dogs with 2 substances, inulin and thiosulphate, one metabolised slowly, the other rapidly. The volume of distribution of inulin, estimated by total recovery from urine after prolonged constant infusion, was 16 to 20 per cent. of bodyweight. The simultaneous volume of distribution of thiosulphate, calculated from plasma content extrapolated to zero time after a single intravenous injection over a 10-min. period, was 20 to 25 per cent. of the bodyweight. Similar results were obtained with both substances in repeated studies in the same dog. Fifty-three per cent. of the injected thiosulphate was excreted in the urine in the first hour, with a maximum recovery of 57 per cent. in 5 hr.

G. F. Garton.

EDWARDS, D. A. W. **Estimation of the proportion of fat in the body by measurement of skin-fold thickness.** *Amer. J. Clin. Nutrit.*, 1956, **4**, 35–36. [Med. Res. Counc., Dept. Clin. Res., University Coll. Hosp. Med. Sch., London, W.C.1.]

Accurate measurements of skin-fold thickness are needed if such thickness is to be taken as a measure of total body fat. Recommendations are made for calliper design based on the results of experiments reported fully elsewhere (Abst. 5545, Vol. 25).—F. C. Aitken.

2786

SUÁREZ, M. Valoracion radiologica de la obesidad. **[Radiological evaluation of obesity.]** *Rev. española Pediat.*, 1955, **11**, 563–570. [Cat. Pediat. Puericult., Santiago de Compostela.]

X-ray techniques were used to estimate the excess of adipose tissue in obese children. From X-ray photographs of the leg the muscular area was calculated and from it the theoretical true bodyweight; the difference between this and the actual bodyweight was taken to be excess fat. The muscle : fat index expressed the relation between the panniculus adiposus and the musculature on X-ray shadows. In infants the anterior abdominal fat thickness was estimated from X-ray photographs.

The paper includes illustrative examples and photographs.—D. Duncan.

DALDERUP, L. M. and JANSEN, B. C. P. **Evaluation of dental caries in the rat in non-decalcified sections of the molars.** *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 235–257. [Netherland Inst. Nutrit., Amsterdam.] German and French summaries.

A method, for which the criteria were accuracy and rapidity, was devised for easy evaluation of the number and extent of carious lesions and their detection at an early stage by microscopic examination at magnification × 40. As a rule 2 sections were made by a sagittal cut of the tooth without decalcification, with saw equipment which is described. The types of lesion likely to be encountered, fissure, approximal, at the cusp summit or more rarely on the smooth buccal and lingual surfaces, are described, and a system of scoring based on measurements of the average length (mesio-distal) and average thickness (occluso-cervical) of the lesion as seen in the section with an estimate of 1 or 2 for the bucco-lingual dimension according as the lesion appeared in one or both halves.

The advantages and the limitations of the technique are fully discussed.—D. Harvey.

MOSQUEDA SUÁREZ, A. Estudio de los métodos "recolección" y "oxido crómico" en la rata. Sus aplicaciones para conocer la digestibilidad de la arepa. [**The recovery and chromic oxide methods with the rat. Application to the estimation of the digestibility of "arepa".**] *Arch. venezol. Nutricion*, 1955, **6**, 71–80. [Inst. Nac. Nutrición.] English and German summaries.

For the composition and preparation of Venezuelan maize bread, arepa, see Abst. 5534, Vol. 25. The digestibility of arepa was studied in experiments with growing rats of initial weight 50 to 55 g. The arepa was dried, ground and fortified with minerals and vitamins and then given to appetite with water. Experiments lasted 14 days, and were made by a total balance method and a chromic oxide method.

Apparent digestibility of protein was 77·6 and true digestibility 95·0 per cent. Total digestibility by the recovery method was 95·0 and by the chromic oxide method 93·6 per cent. The chromic oxide method is considered to have practical advantages over the recovery method.

D. Duncan.

2798

MUELLER, W. J. **Feasibility of the chromic oxide and the lignin indicator methods for metabolism experiments with chickens.** *J. Nutrition*, 1956, **58,** 29–36. [Swiss Poultry Breeding Sch., Zollikofen-Berne.]

Percentage recovery of chromic oxide from the excreta of birds given rations ground to pass a 1-mm. sieve ranged from 95·0 ± 1·46 to 101·2 ± 1·40. Percentage recovery was only 90·6 ± 1·47 when the indicator was mixed in a coarsely ground ration. Significant differences were found between the Cr_2O_3 content of the dry matter of day and night excreta, probably because of the difference in relative amounts of indicator in the intestines and caeca, and the daily emptying of the caeca about a particular time.

Percentage recovery of dietary lignin, which was greatly affected by small alterations in concentration of the H_2SO_4 used for its estimation, ranged from 95·8 ± 1·03 to 105·0 ± 3·42. The diurnal variation in lignin content of the dry matter excreted was less pronounced than in that of Cr_2O_3.

In view of the diurnal variation found, aliquot samples of excreta voided over complete 24-hr. periods are required for accurate measurements of digestibility with indicators such as Cr_2O_3 and lignin.—J. Davidson.

LAZAREV, G. I. Modifikatziya slyunnoi kanyuli u zhvochnykh zhivotnykh. [**Modification of salivary cannula for ruminants.**] *Fiziol. Zh. SSSR Sechenova*, 1955, **41,** 582–583. [Sel'skokh. Inst., Kostroma.]

The technique of inserting a T-shaped cannula into the ruminant parotid duct, permitting sampling without continuous loss of saliva and resulting harmful effects, is described.—D. W. Taylor.

2800

KING, K. W. and SMITH, P. H. **Comparisons of two media proposed for the isolation of bacteria from the rumen.** *J. Bacteriol.*, 1955, **70,** 726–729. [Dept. Biochem. Nutrit., Virginia Agric. Exp. Stat., Blacksburg.]

The media investigated were similar to those used by Gall *et al.* (Absts. 4614, Vol. 17 ; 112, Vol. 23) and by Hungate (*J. Bacteriol.*, 1947, **53,** 631 ; *Bacteriol. Revs.*, 1950, **14,** 1) for the isolation of rumen bacteria. Medium 1 contained much organic nitrogen, with yeast and beef extract ; medium 2 contained rumen fluid. Reducing conditions and CO_2 supply, as well as the inoculation technique, were similar.

With a roll tube technique, the total number of colonies developing, and the numbers and variety of cellulolytic colonies, were greater on medium 2. The rate of cellulose digestion by isolated organisms was also greater on medium 2. This medium, therefore, appeared to be the more suitable.—J. C. Appleby.

A review and discussion of recent work.

2802

HARDISON, W. A., ENGEL, R. W., LINKOUS, W. N., SWEENEY, H. C. and GRAF, G. C. **Fecal chromic oxide concentration in 12 dairy cows as related to time and frequency of administration and to feeding schedule.** *J. Nutrition*, 1956, **58,** 11–17. [Virginia Agric. Exp. Stat., Blacksburg.]

Greater variation was found in the ratio of chromic oxide to dry faeces when Cr_2O_3 was given once daily instead of twice daily. When it was given twice daily the random error of grab samples was one-fifth to one-sixteenth of that when it was given once daily. The time when it was given was without effect. Because variation was found to be greater between cows than between successive experimental periods, it is suggested that in digestibility studies observations should be made on a large number of animals over a short period rather than on a small number over a long period.

FERLAZZO, A., LOMBARDO, G. and CUZZOCREA, G. Azione degli ultrasuoni sulle reduttasi e perossidasi del latte vaccino. [**Action of ultrasonic vibrations on the reductases and peroxidases of cow's milk.**] *Lattante*, 1955, **26**, 504–515. [Ist. Clin. Pediat., Univ. Messina.] English summary.

Five samples of cow's milk were exposed for periods of from 1 to 30 min. to ultrasonic vibrations of 1, 2 and 4 watts. For estimation of peroxidase activity, the fat was removed by centrifuging. Reductase and peroxidase activity were decreased by the treatment. High intensity of ultrasonic vibrations was more effective than long exposure. The changes are attributed to the bacterial action of the ultrasonic vibrations, and it is considered that the method could be applied to the sterilisation of milk.—E. M. Hume.

2810

RICHTER, K. and SCHILLER, K. Untersuchungen zur Bestimmung der Verdaulichkeit und der biologischen Wertigkeit des Milcheiweisses in Magermilchpulvern, die nach verschiedenen Systemen getrocknet wurden. [**Estimation of the digestibility and biological value of milk protein in skimmed milk powder dried by different processes.**] *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 32–37. [Inst. Tierernährung, Völkenrode, Brunswick.] English summary.

The quality of 22 different dried milk samples was compared in chemical tests, by bacteriological assay and in digestibility trials with rats. By chemical estimation the crude protein ranged from 34·8 to 38·7 and the true protein from 32·3 to 37·8 per cent. There was no relation between the protein content and the biological quality. Spray-dried milk was much more soluble than roller-dried. All the samples were free from pathogenic bacteria and usually had low counts of other types, though 2 samples had counts high enough to suggest inadequate pasteurisation before drying.

All the samples had good biological value, especially the spray-dried samples, which were almost as valuable as the egg powder used for comparison. Roller-dried samples processed at low temperatures, 90° and 50° to 60° C., were almost as valuable as spray-dried. Solubility in water had no relation to digestibility.

D. Duncan.

2811

LEPPER, H. A., BARTRAM, M. T. and HILLIG, F. **Authentic packs of edible and inedible frozen eggs and their organoleptic, bacteriological and chemical examination.** *J. Assoc. Off. Agric. Chem.*, 1956, **39**, 185–194. [Food Drug Admin., Dept. Health, Washington 25.]

The results of an official test by smell for edibility of frozen egg were compared with the bacterial counts and contents of formic, acetic, lactic and succinic acids in egg, good, inferior or with admixture of inedible egg, canned in St. Louis in 1941 and in Chicago in 1952 and kept hard frozen.

The findings are tabulated; they confirmed the reliability of the smell test and the conclusions of an earlier study (Abst. 937, Vol. 14), and demonstrated the detrimental effects of delay in freezing, especially with egg mixtures initially of poor quality.—W. M. Deans.

MONZINI, A. and LISSONI, A. La tachipessi applicata alla conservazione delle carni. 3. Digeribilità e modificazioni biochimiche delle carni congelate e conservate a — 25° C e — 40° C per 48 mesi. [**Quick freezing in meat conservation. 3. Digestibility and biochemical modification of meat frozen and stored at — 25° C. and — 40° C. for 48 months.**] *Ann. Sper. agrar.*, 1955, **9**, 1093–1106. [Staz. Sper. Freddo, Milan.] English summary.

3. Veal and beef stored at — 25° and — 40° C. for 10 and 48 months were compared with fresh samples. After 10 months at either temperature the meat contained detectable amounts of ammonia N, not found in fresh samples, and considerably more amino N than fresh meat. Between 10 and 48 months ammonia N rose and free amino N fell. Digestibility by pepsin and trypsin *in vitro* was not much affected by storage for 10 months, but was significantly less after 48 months. Increases in the content of minerals and phosphate extractable by water after cold storage were similar to those found after maturation of fresh meat for 7 days at 2° C. Vitamin B_1 and riboflavin contents were less in frozen than in fresh meat, but the loss of riboflavin was less than the loss during maturation. Catalase activity was reduced by cold storage.

D. Duncan.

Effect of connective tissue collagen on the proteolysis of meat.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102**, 417–426. [Chem. Phys. Inst., Bundesforschungsanst. Fleischwirtsch., Kulmbach.]

For previous parts see Abst. 105, Vol. 23; Title 65, Vol. 25.

3. Results of experiments on the proteolysis of minced muscle, minced tendons or mixtures with pepsin and HCl are presented in tables and graphs. Breakdown products of tendons inhibited the activity of pepsin more strongly than did those of muscle, and fluid taken up by tendons on swelling was less capable of dissolving protein breakdown products than free fluid. In mixtures, the presence of tendons did not affect the rate at which muscle was brought into solution but did retard the breakdown of peptides.—W. M. Deans.

COOKSON, M. A. and COPPOCK, J. B. M. **The role of lipids in baking. 3. Some breadmaking and other properties of defatted flours and of flour lipids.** *J. Sci. Food Agric.*, 1956, **7**, 72–87. [Brit. Baking Indust. Res. Assoc., Chorleywood, Herts.]

For previous parts see Title 2831, Vol. 24.

Literature on flour lipids and their role in breadmaking is reviewed.

Experiments with 80 per cent. extraction flour treated with different solvents for 20 hr. at 15° to 25° C. showed that the properties of the lipids and

of the defatted flours depended on the solvent. Flours extracted with ether or light petroleum had similar dough properties, and also flours extracted with carbon tetrachloride, ether and alcohol, or acetone ; there was little difference between them. Flour extracted with alcohol gave a dough with too low a ratio of extensibility to resistance. Breads made from the other extracted floors were superior to that from unextracted flour in texture and crumb colour, and, except for that from acetone-extracted flour, in loaf volume. The lipids removed by carbon tetrachloride, ether and light petroleum had similar physical and analytical properties ; so had those removed by ether and alcohol or alcohol alone ; those removed by acetone resembled the second group in some ways but not in others. Similar results were obtained with flours of 70 and 100 per cent. extraction.

In further work on flour treated with carbon tetrachloride it was found that defatted flour did not show the usual reduction of extensibility with ageing, and required less of potassium bromate or other improver. Addition of shortening impaired the volume and crumb softness of bread made from defatted flour.

Treatment of flours of 75 or 76 per cent. extraction with chlorine dioxide or agene reduced the amount of lipid removed by solvent, and increased the peroxide value of the lipid extracted from the bread. Bread lipid differed from flour lipid ; it had less free acid, more unsaponifiable matter, a higher peroxide value and a lower, more constant, molar N : P ratio. The ultraviolet absorption spectra of flour lipids were affected by treatment of flour with agene or chlorine dioxide, extraction rate, and baking.

It is concluded that any theory of the mechanism of oxidative improvement of flour must take account of the lipids as well as the proteins. It is suggested that the effect may be due to oxidation of a lipoprotein, not a free lipid or protein. The lipid component essential to the action of shortening is probably not the same. Further work on the fractionation of flour lipids is in progress.

VEENBAAS, A. Het gebruik van keukenzout en fosfaten bij de bereiding van erwten. [**Use of cooking salt and phosphates in the cooking of peas.**] *Voeding*, 1956, **17**, 85–92. [Centraal Inst. Landbouwk. Onderzoek, Wageningen.] English summary.

Peas were steeped and then boiled ; the experiments extend Swedish work (Abst. 3040, Vol. 17). Steeping in 2 per cent. NaCl and boiling without salt improved the physical quality of the boiled pea with 3 varieties, but not the taste, and 1 per cent. had similar effects. With 0·5 per cent. the water need not be changed. Di- and tri-sodium phosphates also made cooking easier, but impaired taste and might destroy more vitamin B_1 than is lost with NaCl.—I. Leitch.

DATE, W. B. **Antioxidant property of some legume flours.** *Science and Culture*, 1955, **21**, 106. [Central Food Technol. Res. Inst., Mysore.]

Legume flours from field bean (*Dolichos lablab*), green gram (*Phaseolus radiatus*), black gram (*P. mungo*), tur (*Cajanus indicus*), pea (*Pisum sativum*), lentil (*Lens esculenta*) and Bengal gram (*Cicer arietinum*) were used to make a sweet product by the method described by Date and Bhatia (*Bull. Central Food Technol. Res. Inst., Mysore*, 1953, **2**, 237). Samples kept in air-tight jars at 37° C. were examined after 2, 4 and 6 months. No sign of rancidity was detected after 2 months, and only in the product from Bengal gram were there traces of rancidity after 4 months. After 6 months all samples were slightly rancid, and the Bengal gram definitely so. The phospholipin content of the flours was estimated and gave similar indications of the keeping quality.—T. D. Bell.

EMILSSON, B. **Treating ware potatoes with sprout-inhibiting chemicals. Research in Sweden 1948-1954.** *Acta Agric. scand.*, 1955, **5**, 390–406. [Inst. Plant Res. Cold Storage, Nynäshamn, Sweden.]

A survey was made of the results of trials on the effect on sprout inhibition, occurrence of disease and cooking quality of potatoes of 6 chemicals : 2 : 3 : 5 : 6-tetrachloro-1-nitrobenzene (TCNB), *iso*-propyl-N-phenylcarbamate (IPC), methyl ester of α-naphthaleneacetic acid (MENA), α-methylnaphthylmethyl ether (METER), phenyl urethane (PU) and maleic hydrazide (MH). The advantages and disadvantages of each are discussed and it is concluded that TCNB and IPC are to be recommended, under Swedish conditions, for sprout inhibition. With all chemicals there was less darkening of the potatoes after cooking, as compared with untreated tubers, but the difference was most marked with TCNB, IPC and PU.—J. S. Thomson.

HURKA, W. Die Konservierung von Orangen für den Transport. [**The preservation of oranges for transport.**] *Lebensmittel u. Ernährung*, 1956, **9,** No. 2, 8–9. [Mikrobiol. Lab., Arcana KG, Lieserbrücke.]

Losses of oranges during shipment can be cut from 10 to under ½ per cent. by wrapping the fruit in paper impregnated with diphenyl; the amount of the latter in the peel of an orange of average size ranges from 2·4 mg. after 14 days to 5·6 mg. after 62 days. Although short-term experiments with rats at the National Institute for Medical Research have shown that diphenyl at the rate of 200 mg. per kg. bodyweight is not demonstrably toxic, it is considered that diphenyl and similar substances should not be used until tests lasting much longer have proved them to be harmless.—W. M. Deans.

ARROYAVE, G., PINEDA, O. and SCRIMSHAW, N. S. **The stability of potassium iodate in crude table salt.** *Bull. World Health Organiz.*, 1956, **14,** 183–185. [Div. Clin. Biochem., Inst. Nutric. Centro América y Panamá (INCAP), Guatemala.] French summary.

In many areas where goitre is endemic, the iodisation of salt by conventional methods with NaI or KI is not practical because of losses due to impurities, moisture, light and heat. The data presented show that addition of KIO_3 is easier and more reliable. A mixture of 1 part KIO_3 with 9 parts $CaCO_3$ was added to salt obtained by solar evaporation of sea water; the final product contained approximately 1 part added I per 10,000 parts of salt. To test the stability of the I a sample of 50 kg. was stored in a hemp fibre sack in an open room from January to August, a period which included 4 dry- and 4 rainy-season months when average humidities were 70 and 84 per cent., respectively. Samples for analysis were taken from the upper, middle and lower parts of the sack. Only 3·5 per cent. of the added I was lost during the whole period and there was no shift of I from one layer to another.—B. W. Simpson.

DIJKSTRA, N. D. and DAMMERS, J. Bewaringsproeven met gemoesde bieten. [**Tests in preservation of beet pulp.**] *Landbouwvoorlichting*, 1954, **11,** 377–379. [Rijkslandbouwproefstat., Hoorn.]

When fodder or sugar beet is stored for pig feeding it would be convenient to store it as pulp. Tests in which beet pulp alone, and equal quantities of beet pulp and steamed potatoes, were stored in small concrete silos gave percentage losses as follows: dry matter 27·2 and 45·8; organic matter 37·1 and 54·4; crude protein 33·3 and 27·8; N-free extract 40·6 and 60·9 and crude fibre 8·4 and 10·4. Storage as pulp is therefore not recommended.—I. Leitch.

2831

DIJKSTRA, N. D. and SPRENGER, J. J. I. Proefnemingen over de achteruitgang van de verteerbaarheid bij het kunstmatig drogen van lucerne. [**The influence of artificial drying on the**

digestibility of lucerne.] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61·11, pp. 30. [Rijkslandbouwproefstat., Hoorn.] English summary.

At one centre a single lot of lucerne was chopped and dried and analysed fresh and dried as chopped, ground and cubed. At another, lucerne was cut early, at the usual time, and late, dried in a high- and a low-temperature drier and analysed fresh and as dried and ground. Also of that cut at the normal time and dried in the high-temperature drier, samples were analysed, chopped, ground and cubed. Digestibility was estimated *in vitro* and *in vivo* at the Hoorn research station.

For earlier similar work with grass see Abst. 197, Vol. 26. Results with lucerne were similar. Digestibility fell over the growing season. High-temperature drying reduced digestibility of protein by, on the average, 9·5 per cent. Grinding and cubing further reduced it. Loss was less in the early-cut crop dried in the low-temperature drier, 4·7 per cent., and higher in the normal- and late-cut dried in the high-temperature drier, 19·8 and 10·3 per cent. Loss of digestibility of organic matter was much less; in the chopped lucerne, 1·0, in meal 2·7 and in cubes 5·1 per cent. on the average.

Digestible crude protein estimated *in vitro* was about 1·5 per cent. more than that estimated with wethers.—I. Leitch.

2832

RULIFFSON, W. S., MILNER, M. and MITCHELL, H. L. **Feedstuffs values and chemical changes in spontaneously heated alfalfa pellets.** *J. Agric. Food Chem.*, 1956, **4**, 167–170. [Kansas State Coll., Manhattan.]

Samples of alfalfa pellets at different stages of decomposition were obtained from a commercial elevator bin in which spontaneous combustion had occurred. Round the sides of the bin the pellets were normal but at the centre they had become a black congealed mass, with intermediate stages of degeneration between. Chemical analyses showed a tendency to a decrease of moisture content as deterioration progressed, a marked increase of ash, an increase of crude protein until the last stage of decomposition, a marked increase of crude fibre, with a concomitant decrease of available carbohydrate, and a gradual decrease of ether extract till near the final stage, when the decrease became very marked. Changes in amino acid N and in N.P.N. were not rapid until the final stages of deterioration. Carotene was lost rapidly but there was an apparent increase of riboflavin at the intermediate stages, followed by a rapid fall. Fluorescence rose rapidly till near the final stage, indicating a reaction between protein and sugar.

J. S. Thomson.

2833

KING, W. H., WOLFORD, L. T., THURBER, F. H., ALTSCHUL, A. M., WATTS, A. B., POPE, C. W. and CONLY, J. **Effect of *p*H during the cooking of cottonseed on the properties of meals and oils.** *J. Amer. Oil Chem. Soc.*, 1956, **33**, 71–74. [S. Reg. Res. Lab., New Orleans.]

Cottonseed meats were cooked for 30 min. with stirring in water at a temperature rising to not more than 212° F. Moisture was kept high at the beginning in order to break down the pigment glands and release gossypol. Variation of *p*H was obtained by the addition of orthophosphoric acid or NaOH. The resulting meals were high in soluble N and their nutritive values, measured by the growth rate of day-old chicks, surpassed at the optimum *p*H levels, about 5·0 and 7·0, those of meal extracted with butanone to remove gossypol. The amount of gossypol in the meals increased as *p*H rose. Free gossypol in alkali-cooked meals ranged from about 0·02 to 0·05 and in the acid-cooked meals from about 0·03 to 0·08 per cent. Total gossypol ranged from 0·4 for acid-cooked to 1·2 for alkali-cooked meals. The bleached oils from meats cooked at a low *p*H were subject to colour reversion; those cooked at a high *p*H were not.

See Absts. 5613, Vol. 21; 1739, Vol. 25.

A. Hepburn.

2834

MCDONALD, P. and PURVES, D. **Effects of the addition of molasses on the composition and digestibility of field silages.** *J. Sci. Food Agric.*, 1956, **7**, 189–196. [Edinburgh and East of Scotland Coll. Agric., 13 George Sq., Edinburgh 8.]

Silage was made from grass, chiefly perennial ryegrass, and clover sown in 1952 under oats and cut in 1954 when the grass seed heads had fully emerged. Two small concrete silos, capacity 750 kg. fresh crop, were filled in one day, with consolidation of each load. One silo had molasses diluted with about the same amount of water added at the rate of 1·34 kg. per quintal of fresh herbage. The silage was covered with paper, soil and a lid. Temperatures rose initially to 23° and 22° C. and were stabilised at approximately 14° and 15° C. at 14 days. The ordinary silage was removed after 11 and the molassed silage after 14 weeks.

Composition and digestibility by wethers of the grass as cut and of the silages are recorded in terms of the usual components, soluble sugars and fructosan. Losses were extremely small; the only proportionately substantial changes were apparent gains of ether extract and crude fibre. The ordinary silage lost 23·3, molassed silage 49·5 per cent. of soluble sugar; untreated silage lost 82·6 per cent. of fructosan; molassed silage gained 39 per cent. Total weights of lactic and acetic acids were, in kg., in ordinary silage 12·53

and 1·52 ; in molassed silage 14·07 and 2·21, and greatly outweighed the total loss of soluble carbohydrates.

There was no difference in digestibility or calculated feeding value between grass and either silage, or ordinary silage with added molasses.

I. Leitch.

2835

DE VUYST, A., VANBELLE, M., VERVACK, W. and IMBERECHTS, R. Analyse critique de la qualité des ensilages réalisés en région herbagère. [**Critical analyses of silage quality in pasture - producing regions.**] *Rev. Agric., Brussels,* 1955, **8,** 1159–1172. [Centre Recherches Zootech., Univ. Louvain.] English and German summaries.

In the Fagne pasture region of the south of Belgium silage is made usually in stacks from wilted herbage built up, a load at a time, with intervals of 1 or 2 days. To build a stack may take 15 days to a month. When complete it is covered with a layer of earth supported by a wooden frame. The sides are not protected : no preservative is used and heating is not controlled.

Samples were taken from 83 silos, 69 stack silos, 12 concrete silos and 6 tower silos of steel ; 75 had no preservative and of these 62 were stack silos; *p*H, lactic, acetic and butyric acids and total and ammonia N were estimated. The results are analysed statistically. Quality was equally bad in stack and closed silos if, as was usual, heating was not controlled ; *p*H was high, average 5·35 ; butyric acid was high and lactic acid low ; in two-thirds of the silos more than 15 per cent. of protein was lost and the ratio of ammonia to total N was above 30 per cent. The recommendation is to make " cold " silage from chopped, wilted herbage.

I. Leitch.

2836

BRATZLER, J. W., COWAN, R. L. and SWIFT, R. W. **Grass silage preservation with sodium metabisulfite.** *J. Animal Sci.,* 1956, **15,** 163–176. [Pennsylvania State Univ., University Park.]

The 1952 experiments described in the first part of the paper have been more fully reported elsewhere (*Pennsylvania Agric. Exp. Stat. Bull.* 597 (1955)) ; for preliminary reports see Absts. 3322, Vol. 25 ; 201, Vol. 26). Materials, unwilted, and additions per ton were : orchard grass, chopped, 8 lb. sodium metabisulphite or 80 lb. molasses, or nothing ; alfalfa and bromegrass, 7·5 or 10·5 lb. bisulphite or 70 lb. molasses, or nothing ; alfalfa, chopped, 9·4 or 36·4 lb. bisulphite (excessive) or nothing ; alfalfa, chopped, 8 lb. bisulphite or 5 lb. gaseous SO_2. The silages were examined and tested with sheep and cattle after 4 summer or 6 winter months. All the silages made with sodium metabisulphite, except that with the highest amount, had better colour and odour, and the first 2 kinds had more carotene, than the silages made with molasses or without addition, and losses of carbohydrate were generally at least halved, with a saving more than enough to pay for the chemical. Trials with sheep showed that total digestible nutrients exceeded those of silage made without addition, and cattle readily ate the bisulphite silages.

Further experiments were made in 1953 on alfalfa, with 8 lb. bisulphite or nothing ; red clover, with 7 lb. bisulphite, 112 lb. molasses or nothing ; and a mixture of the two with dried beet pulp, with or without 11 lb. bisulphite. The addition of bisulphite again improved silage quality and reduced losses ; molasses and dried beet pulp improved quality somewhat, but did not reduce losses.

W. M. Deans.

2837

SUTTER, A. Silierungsversuche mit einem streufähigen Sicherungszusatz. [**Silage experiments with a powder preservative.**] *Schweiz. Landwirtsch. Monatsh.,* 1956, No. 1, Sonderheft 60. Geburtstag. Prof. Crasemann, 66–71. [Chem. Fabrik Uetikon.]

In spring and autumn 1954 trials were made on 17 farms with Conservit, a powder based on salts containing SO_2 with other preservatives, added at the rate of 500 g. per 100 kg. to grass, clover-grass or other mixtures, generally fresh and unchopped. In 16 of the 24 trials similar material was ensiled with A.I.V. acid or formic acid for comparison. Samples were taken after 6 to 8 weeks and from the spring silages also in late autumn.

All but 3 of the silages were considered good ; the failures were ascribed to loose packing. The Conservit silage was greenish, darkening rapidly on exposure ; the smell was grassy rather than aromatic and not so penetrating as that of the comparison silages. It was readily eaten without ill effect. The mean *p*H was 4·6 compared with 4·0 for the comparison silages, but the usual limiting value of 4·2 does not apply to Conservit silage. The amounts of ammonia and lactic acid were about the same, but the Conservit silage had less acetic and butyric acids. Small-scale tests not reported in detail suggested that losses of nutrients would be of the same order as from A.I.V. silage, about 10 per cent. The crop can be ensiled wet or dry ; wilting is not recommended.—W. M. Deans.

2838

KEMBLE, A. R. **Studies on the nitrogen metabolism of the ensilage process.** *J. Sci. Food Agric.,* 1956, **7,** 125–130. [Dept. Chem., King's Bldgs., Univ. Edinburgh.]

With quart milk bottles as containers, bad and good silage was made from young perennial ryegrass (4·71 per cent. N in the dry matter) by adding a suspension of anaerobic bacteria, or a

suspension of lactobacilli along with glucose solution. After storage at 30° C. for 1 and 3 days and 1, 3, 8 and 21 weeks, total and soluble N, volatile base, total amide, glutamine, α-amino N, alcohol-insoluble peptide N and free amino acids were estimated by methods described earlier (Absts. 304, 305, Vol. 25). Also, young timothy from a sterile growth chamber, ensiled in a test tube, was examined after 16 days.

The results are tabulated and show a rapid rise of amino acids in the first 3 days; even in the good silage, about one-third of the protein was broken down at this stage. Later, even at *p*H 3·8 there was a slow steady rise of soluble N, so that it was possible to have a silage with the *p*H, volatile base content and odour of good silage although half the original protein had been broken down. The amounts of amino acids found, except for alanine in the bad silage, were less than those calculated from the rate of protein breakdown. Results for the silage from sterile grass indicated that the excess alanine, and the rapid initial breakdown of protein, are due to the plant enzymes, not to micro-organisms.—W. M. Deans.

2839

ANDERSON, K. J. **Microbiology of silage.** *Nature*, 1956, **177**, 96–97. [Dept. Agric. Botany, King's Coll. (Univ. Durham), Newcastle upon Tyne.]

About 40 g. mixed perennial ryegrass and white clover was packed under sterile conditions into small glass tubes. Lactobacilli were present in relatively small numbers in the fresh grass. After 7 weeks the numbers in long or chopped grass packed without addition had greatly increased. Addition of sterile water or 0·2 g. sodium metabisulphite resulted in a higher *p*H. Water increased the numbers of coliform bacilli and anaerobic spore formers. Metabisulphite considerably reduced the total bacterial count.

The best silage was from long grass without addition and the worst from wet long grass; that made with metabisulphite had a pleasant smell but an unnaturally bright green colour.

J. L. Corbett.

CULTURE OF MICRO-ORGANISMS FOR FOOD

2840

CHALLINOR, S. W. and DANIELS, N. W. R. **Fat production by inositol-deficient yeast.** *Nature*, 1955, **176**, 1267–1268. [Dept. Appl. Biochem., Univ. Birmingham.]

Yeast cells growing in a medium deficient in inositol became unhealthy in appearance and were easily ruptured to liberate fat. The yield of fatty substances from cells harvested after 5 days, dried, ground and extracted with light petroleum was 24·5 per cent., compared with only 1·6 per cent. from normal cells. When the source of N, ammonium hydrogen phosphate (0·237 per cent.), in the medium was decreased the fat was not so easily liberated and extraction was not quite complete, although the yields were not greatly different. Only about 9 per cent. less fat was obtained when grinding was omitted.—A. Hepburn.

TITUS, H. W. **Energy values of feedstuffs for poultry.** Reprinted from *The Scientific Feeding of Chickens*, Interstate Printers and Publishers, Inc., Danville, Ill., 1955, pp. 245–267, by Limestone Products Corporation of America, Newton, N.J.

Credit is given to G. S. Fraps of the Texas Agric. Exp. Stat. for most of our knowledge of *productive energy* of feeds for poultry. His definitions are discussed. Fraps ignores crude fibre in making his computations, although 10 per cent. or more of the crude fibre of many grains and 40 per cent. or more of the crude fibre of a mixed feed may be digested. His calculations of metabolisable energy are faulty in that they assume that protein and starch have the same value, 4·2 Cal. per g. and fat has 2·25 times that value. But protein has on the average a value of only 3·84 Cal. per g. and a carbohydrate such as sucrose, found in appreciable quantity in some feeds, has a value of only 3·96 Cal. per g. And again, crude fibre is ignored. Productive energy is defined as

net energy as measured by stored protein and fat. Storage can never be measured accurately, since it cannot be estimated in the same chicks, and maintenance requirements cannot be accurately distinguished. Fraps's equations involve assumptions that are not correct. Further, productive energy value differs with what is produced ; there are no data for productive energy values for eggs.

There are other reasons why Fraps's productive energy values should not be used blindly. The data he uses for composition are not always *generally* valid and hence his " factors " for computing " effective digestible nutrients " and energy value are unreliable.

Tables 15 to 19 make comparisons between data for digestibility as given in the textbook from which this chapter is reprinted, p. 14, and some of Fraps's data and the derived data for total digestible nutrients, metabolisable and productive energy; factors for computing energy values ; protein, total and digestible, T.D.N., Fraps's productive energy calculated with digestibility data from the textbook, and (textbook) metabolisable energy for a list of the common poultry feeds, and finally Fraps's productive energy as originally given for much the same list.—I. Leitch.

CARPENTER, K. J. and CLEGG, K. M. **The metabolizable energy of poultry feeding stuffs in relation to their chemical composition.** *J. Sci. Food Agric.*, 1956, **7**, 45–51. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Brown Leghorn × Light Sussex hens were used in metabolism experiments with a 13-hr. day, a temperature of 50° F. and 6-day collections. Cereals were given with Ca and P, NaCl and cod liver oil, or with these supplements and 8 per cent. casein. There was little difference between the results. Cereals studied were maize, sorghum, wheat (2 samples), barley (2), oats (3), wheat offals (3 grades) and maize gluten feed ; mixed rations were maize and fishmeal, maize and soya bean meal, barley and fishmeal, and mixed cereals. Table 2 shows the composition in terms of crude protein, ether extract, fibre, ash, nitrogen-free extract, starch and sugars ; and gross energy by bomb calorimeter, metabolisable energy as estimated from the digestion experiments by deduction of the gross energy of the excreta, and metabolisable energy as computed from the formula 53 + 38 (per cent. crude protein + 2·25 × per cent. ether extract + 1·1 × per cent. starch + per cent. sugar).

Metabolisable energy as a percentage of gross energy was least for coarse bran and greatest for maizemeal. The proportion of N-free extract from starch plus sugars varied from 27 per cent. for coarse bran to 87 per cent. for sorghum. The prediction formula underestimated metabolisable energy in 7 of the 9 cereal samples and overestimated it in wheat offal and 3 of the 4 mixed rations. Alternative formulae, including one with a correction for crude fibre, did no better. Comparisons are made with earlier data.

When requirements, *e.g.*, for protein as estimated with different rations are re-computed in relation to metabolisable energy instead of weight of ration, discrepancies disappear.—I. Leitch.

OSMOND, A. **The composition of mature human milk in southern Tasmania.** *Med. J. Austral.*, 1953, i, 811–814. [Pub. Health Dept., Tasmania.]

In child welfare centres in and around Hobart 24-hour samples of milk were collected in the late autumn and winter from 24 healthy nursing mothers, aged from under 20 to over 40 years, with infants aged between 8 and 24 weeks. All continued to feed their babies for at least 3 weeks after the sample was taken. Milk was expressed from one breast in an amount equal, if possible, to that taken by the infant from the other breast. The expressed milk was well mixed ; 1/5 of it was taken for analysis, and all the fractions were pooled and stored in the refrigerator.

The range within which 95 per cent. of the values for nutrients, in g. per 100 g., might be expected to fall was for protein (Kjeldahl) 0·94 to 1·30, fat (Gerber) 3·16 to 5·88 and carbohydrate (by difference) 6·75 to 7·55. The calculated energy value was 16·7 to 23·8 Cal. per 100 g. Ca, P and ash were estimated also.

The babies were weaned when from 15 to 40 weeks of age ; no relation existed between the duration of lactation or age of the baby and the composition of the milk at the time of sampling. The age of the mother had no influence on any constituent except fat, which was lower in mothers under 20 years of age.

From other data collected during the investigation, it was concluded that a single test feed, or the analysis of an isolated 24-hour-sample of milk from a nursing mother, is of doubtful value for any practical purpose.—M. H. Pierce.

MONTREUIL, J. Structure de deux triholosides isolés du lait de femme. [**Structure of two triholosides isolated from human milk.**] *C.R. Acad. Sci.*, 1956, **242,** 192–193.

Two trisaccharides isolated from human milk (see Abst. 250, Vol. 25) were treated with dilute Na_2CO_3 solution at 100° C. for 5 min. This procedure transformed the reducing group into a ketose (fructose), which was then degraded to leave a disaccharide. One trisaccharide so treated was shown by chromatography to yield a trisaccharide containing fucose, galactose and fructose and a disaccharide containing fucose and galactose. The structure was concluded to be α-L-fucosido-2β-D-galactosido-4-D-glucose. The other trisaccharide yielded only galactose and fucose and the structure was concluded to be β-galactoside-4 $\left.\begin{matrix}\\ \beta\text{-fucosido}\end{matrix}\right\rangle$glucose.

RAPI, G. and ROSSI, R. Ricerca degli ormoni steroidi nel latte umano ; (alcuni rilievi sulla reazione di Porter e Silber). 1. Indagini sul colostro. [**Steroid hormones of human milk, with comments on the reaction of Porter and Silber. 1. Experiments on colostrum.**] *Riv. Clin. pediat.*, 1955, **56,** 267–280. [Ist. Chim. Organ., Univ. Florence.] English and French summaries.

Steroid hormones were extracted from a pooled sample of from 500 to 600 ml. human colostrum by the method of Kuizenga and Cartland (*Endocrinology*, 1939, **24,** 526). The extract was tested for power to promote the survival of immature mice weighing from 9 to 11 g. from which the adrenal glands had been removed. The presence of adrenocortical steroids was demonstrated. Chemical tests were made on the extract of colostrum by the methods of Heard and Sobel (*J. Biol. Chem.*, 1946, **165,** 687), Porter and Silber (*J. Biol. Chem.*, 1950, **185,** 201) and Zimmerman [no reference], but failed to identify the steroids. It was found that a positive reaction in the test of Porter and Silber was given by dehydro*iso*androsterone as well.—E. M. Hume.

WAITE, R., WHITE, J. C. D. and ROBERTSON, A. **Variations in the chemical composition of milk with particular reference to the solids-not-fat. 1. The effect of stage of lactation, season of year and age of cow.**

ROBERTSON, A., WAITE, R. and WHITE, J. C. D. **2. The effect of heredity.** *J. Dairy Res.*, 1956, **23,** 65–81 ; 82–91. [Hannah Dairy Res. Inst., Kirkhill, Ayr ; Inst. Animal Genetics, Edinburgh.]

1. Between February 1950 and November 1953 over 6000 samples of milk were collected from 33 milk-recorded farms in south-west Scotland. The cows were 814 pedigree Ayrshires, 374 dams and 504 daughters ; some dams had more than 1 daughter and, in a few cases, 3 generations were represented. The samples were composite ones of proportional amounts from consecutive evening and morning milkings, and numbered 6 from each cow at intervals of about 5 weeks. Estimations were made of total solids, fat, crude protein, casein and lactose and of solids-not-fat (SNF) by difference. Feeding and management followed local practice ; nearly half the cows calved in the first 4 months of the year, and winter feeding was with hay, straw and roots for maintenance and concentrates for production ; in summer there was grazing with only very small amounts of concentrates. The data for 4988 samples of milk were analysed statistically in order to study separately the effects on milk composition of stage of lactation and of season.

With advancing lactation there was for yield and lactose content a rise to a maximum 45 days after calving and thereafter a steady fall. Values for the other constituents moved in the opposite direction to a minimum at 45 days for SNF, crude protein and casein and at 75 days for total solids and fat, and thereafter rose steadily until the end of lactation. The effects of season were both smaller and more irregular. Yield rose in the early part of the year to a maximum in May or June and then fell to a minimum in October or November. Fat was highest in October and lowest in June. The curves for crude protein and casein showed

peaks in May-June and September; their lowest levels were between January and March. Lactose varied little between January and June and after falling remained at a lower level from August to December. Both total solids and SNF were lowest in March and April, but while SNF were highest in May and June, total solids were so in October.

There was no evidence from cell counts of inflammatory disease having had any appreciable effect on the composition of the milk. In comparison with those of Tocher, "Variations in the Composition of Milk", H.M.S.O., Edinburgh, 1925, the data support the view that there has been little change in the last 30 years in the composition of milk from Ayrshire cows in Scotland (see also Davis, Abst. 1411, Vol. 23). Among the 4988 samples 782 with less than 8·5 per cent. were deficient in SNF and 97 with less than 3 per cent. were deficient in fat. The proportion of samples low in SNF increased with the number of lactations.

2. The lactation records were used to estimate heritability by the dam-daughter correlations within herds. The variation of SNF was determined largely by that of casein. The correlation between lactose and casein also was positive. There were positive and significant genetic correlations between casein and both fat and lactose; selection for fat content and yield may check a decline in SNF. Analyses for SNF are desirable where the aim is to raise the level in a herd.

SCHÄFER, K. H., BREYER, A. M., HORST, W., KARTE, H. and LENZ, W. Die Proteinbindung des Eisens in der Milch. [**Binding of iron by protein in milk.**] *Klin. Wochenschr.*, 1956, **34**, 300–304. [Kinderklin., Univ. Hamburg, Eppendorf.]

The nature of the iron complex in human and cow's milk was studied by precipitation with ammonium sulphate and sodium sulphate, by electrophoresis in solution and on paper and by ultra-centrifuging. The protein carrying the Fe was identified in the globulin component and not in the lactalbumin. The complex containing Fe showed a pale red colour in centrifuged samples and the colour was increased in milk from subjects receiving treatment with Fe. The capacity of milk protein to bind Fe was less than that of serum protein. The coloured protein-iron complex was separated by paper electrophoresis in the region which was associated with β-globulin in serum electrophoresis. The possible similarity of the proteins capable of binding Fe in milk and blood is discussed.

2854

MULDER, H. De smaak van melk. [**The taste of milk.**] *Voeding*, 1956, **17**, 45–50. [Landbouwhogesch., Wageningen.]

The true taste of milk comes from lactose, not from its protein or fat, except in late lactation when salt content rises and lactose falls, and then milk tastes salty, or watery. Secondary tastes derive from abnormalities of the cow, *e.g.*, ketosis, from feed (hay is good, silage, roots and leafy crucifers are bad), from chemical changes due to enzyme action or processing, or from contaminants. Temperature greatly affects acceptibility; flavouring has little effect.—I. Leitch.

MAURON, J., MOTTU, F., BUJARD, E. and EGLI, R. H. **The availability of lysine, methionine and tryptophan in condensed milk and milk powder. *In vitro* digestion studies.** *Arch. Biochem. Biophys.*, 1955, **59**, 433–451. [Res. Lab., Nestlé's Products, Vevey, Switzerland.]

The destruction, taken as the amount not recovered by acid hydrolysis, and the inactivation, taken as the amount liberated by this treatment but not by enzymic hydrolysis, of α-amino groups, tryptophan, tyrosine, methionine and lysine were estimated in fresh and boiled milk, spray-dried and roller-dried milk, sweetened condensed milk and evaporated milk. The inactivation was measured by a digestibility test with pepsin and pancreatin *in vitro*.

Tryptophan, tyrosine and methionine were not destroyed in any milk. The percentage destruction of lysine was spray-dried milk 3·6, sweetened condensed milk 4·8, evaporated milk 8·4, roller-dried milk 13·3, slightly scorched roller-dried milk 26·5. The inactivation of lysine in the last 3 was 11·2, 20·0 and 45·8 per cent. Six per cent.

destruction and 12·4 per cent. inactivation of α-amino groups was found in the scorched roller-dried milk. Tryptophan and tyrosine were not inactivated and methionine was slightly inactivated in roller-dried milks only.

Destruction and inactivation of lysine were closely correlated. Both were attributed to a sugar-amine condensation. The availability of lysine was calculated by deducting total deterioration, *i.e.*, destruction plus inactivation, from 100, the value given to fresh milk. The lysine availability (y) in industrial milks could be estimated from the lysine destruction (x) by means of the regression equation

$$y = 109{\cdot}58 - 3{\cdot}099\,x.$$

The phosphatase systems of sour milk cheese and their development during ripening.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103,** 14–32; 211–238. [Inst. Lebensmittelchem., Tech. Univ., Berlin-Charlottenburg.]

For references to previous parts see Abst. 171, Vol. 26.

15. For the estimation of serine and threonine in ripening Harz cheese the methods of Rees (Abst. 3812, Vol. 16) and of Neidig and Hess (Abst. 1232, Vol. 23), were tested and the former was adopted.

Nearly 20 per cent. of the serine was lost during normal ripening or ripening without added salts; much less during rapid ripening. Only about 7 per cent. of the threonine was lost during normal ripening; much more during rapid ripening or ripening without salt. In view of the biological importance of threonine, rapid ripening is not recommended. Only small amounts of the free amino acids were found in ripe cheese.

The enzymic breakdown of serine and threonine in cheese suspensions with or without added B vitamins was also studied. In the first few days of ripening pyridoxal phosphate affected serine and threonine equally, but later it increased the loss of serine much more than that of threonine. Biotin also had 3 times as great an effect on serine as on threonine. Pantothenic acid, and to a less extent folic acid, affected both equally. The breakdown products α-alanine and α-aminobutyric acid were detected by paper chromatography. In the discussion it is suggested that, though the presence of B vitamins in cheese is desirable on nutritional grounds, too great amounts may interfere with the normal ripening process and lead to breakdown of essential amino acids.

16. Phosphatase activity was measured with disodium phenyl phosphate as substrate by the method previously described (Abst. 3259, Vol. 25). Ripe cheese contained an alkaline phosphatase, *p*H optimum 9·95 to 10·2, and smaller amounts of an acid phosphatase, *p*H optimum 5·2 to 5·7. The alkaline phosphatase was not that of the milk but developed during ripening, rising to a maximum after 10 to 14 days and starting in the rind. The acid phosphatase was present in the curd and rose to a plateau after 10 or 11 days. There was also a pyrophosphatase, *p*H optimum 6·3. Their properties are described in detail. The power of the acid phosphatase to split fructose diphosphate and pyridoxal phosphate indicates that it may play an important part in cheese ripening.—W. M. Deans.

NOTTINGHAM, P. M. **The connective-tissue content and toughness of sheep muscles.** *J. Sci. Food Agric.*, 1956, **7**, 51–56. [Dominion Lab., D.S.I.R., Wellington, N.Z.]

In rectangular blocks of semimembranosus, rectus femoris, gluteus superficialis, longissimus dorsi and psoas muscle taken 24 hr. after slaughter from sheep between 1 and 2 years old, mostly Southdown × Romney crosses, shear force parallel to and across the muscle fibres was measured and connective tissue content was ascertained by extraction with cold 0·1 *N* NaOH and estimation of N in the residue.

Connective tissue ranged from 0·39 to 0·64 per cent. of wet weight and connective tissue N formed on the average from 2·14 to 3·60 per cent. of total protein N, varying with the muscle and from animal to animal. When the results from 17 muscles of 7 sheep were combined, the correlation coefficient between connective tissue content and shear force parallel to the fibres was + 0·784, but connective tissue content and shear force across the fibres were not related. As meat is usually carved across the grain, this suggests that connective tissue content is one of the factors affecting the toughness of mutton.—W. M. Deans.

Cooked hams from pigs fed on groundnuts were judged to be juicier, more tender and less salty, and had a less compact lean and a less desirable fat layer than hams from pigs fed on maize. There was little difference in chemical composition except for a higher vitamin B_1 content of the hams and a higher iodine number of the fat in the pigs fed on groundnuts.—J. S. Thomson.

2865

PRESTON, R., CHENG, E., STORY, C. D., HOMEYER, P., PAULS, J. and BURROUGHS, W. **The influence of oral administration of diethylstilbestrol upon estrogenic residues in the tissues of beef cattle.** *J. Animal Sci.*, 1956, **15**, 3–12. [Iowa Agric. Exp. Stat., Ames.]

A method capable of detecting 2 μg. stilboestrol per kg. tissue by its effect on weight of the mouse uterus showed no residue of oestrogen in tissues of beef cattle given stilboestrol.—T. R. Preston.

2866

TURNER, C. W. **Biological assay of beef steer carcasses for estrogenic activity following the feeding of diethystilbestrol at a level of 10 mg. per day in the ration.** *J. Animal Sci.*, 1956, **15**, 13–24. [Dept. Dairy Husb., Missouri Agric. Exp. Stat., Columbia.]

Samples of edible meat, glands and organs, depot fat, blood and digestive tract from 20 Hereford steers given stilboestrol and 10 controls given none, were tested for oestrogenic residues by the mouse uterine weight technique. No oestrogen was detected in any of the tissues except the kidney and lungs of treated animals, which contained 0·004 and 0·012 p.p.m. oestrogen, respectively. Tests on the feeds demonstrated the oestrogenic potency of the ration containing stilboestrol and also revealed a surprisingly high oestrogenic activity of the control diet. Faeces from dairy cattle given 10 mg. stilboestrol daily revealed oestrogenic activity comparable with that of the feed containing stilboestrol.—T. R. Preston.

2867

WOOD, T. **Some applications of paper chromatography to the examination of meat extract.** *J. Sci. Food Agric.*, 1956, **7**, 196–200. [Res. Dept., Bovril, Ltd., 148 Old St., London, E.C.1.]

Protein (12 per cent.) was removed by dialysis and inorganic salts (29 per cent.) electrolytically. The chief solvent mixture used for chromatography was butanol : acetic acid : water (60 : 15 : 25). Glutamic acid, serine, α- and β-alanines, glycine, proline, methylhistidine, carnosine, anserine, creatinine, creatine, methylguanidine, guanidine, choline, carnitine, hypoxanthine, inosine, urea and citrulline were identified: betaine and sugars were not detected.—H. G. Bray.

2868

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. **The branched-chain fatty acids of ox fat. 3. The isolation of 14-methylpentadecanoic acid (*iso*palmitic acid) from ox perinephric fat.**

Biochem. J., 1955, **61,** 547–549. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

3. From the hydrogenated ox perinephric fat used in previous studies (Absts. 245, Vol. 22; 222, Vol. 26), 14-methylpentadecanoic acid was isolated, by ester-fractionation and low-temperature crystallisation, in amount corresponding to 0·1 per cent. of the total fatty acids.—G. A. Garton.

2869

HARTMAN, L., SHORLAND, F. B. and MCDONALD, I. R. C. **The *trans*-unsaturated acid contents of fats of ruminants and non-ruminants.** *Biochem. J.*, 1955, **61,** 603–607. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

The *trans* fatty acid content of the depot fats of several species of animals was estimated by infrared spectrophotometry. The depot fats of ruminants (ox, cow, fallow deer, sambur, goat and sheep) contained from 3·5 to 11·2 per cent. of *trans*-acids, and that of non-ruminants (rat, pig, horse, rabbit and pheasant) not more than 0·9 per cent. Certain marsupials, *e.g.*, wallaby and quokka, had depot fats in which the proportion of *trans*-acids ranged from 18·1 to 21·0 per cent.

It is concluded that *trans*-acids arise by hydrogenation by bacteria of dietary unsaturated fatty acids in the rumen or in the rumen-like stomach of the marsupial.—G. A. Garton.

2870

HART, P. C. Onderzoekingen omtrent de zachtheid van bacon. 2. Spekhardheid en chemische samenstelling. [**Studies on the softness of bacon. 2. Hardness of fat and chemical composition.**] *Landbouwk. Tijdschr.*, 1956, **68,** 307–313. [Inst. Veeteeltk. Onderzoek TNO, Utrecht.] English summary.

For part 1 see Abst. 57, Vol. 26.

2. Analysis of 345 samples of lard showed that method of extraction did not affect the results, nor did the curing process alter either iodine or thiocyanate value. These increased together, with increase in percentage of linoleic acid, and were inversely related to saturated fatty acids and to oleic acid, which showed little variation. Hardness of fat as assessed by thumb pressure was closely related inversely [not directly as stated in the English summary] to linoleic acid content.

OLLEY, J. **7. Phosphate esters in the lipids of haddock and cod flesh.** *Biochem. J.*, 1956, **62,** 99–107; 107–114. [Food Invest. Organiz., D.S.I.R., Torry Res. Stat., Aberdeen.]

For previous parts see Absts. 4042, Vol. 23; 229, 1642, Vol. 24; 274, Vol. 25.

6. Solvent extracts were prepared from 43·74 kg. cod flesh and fractionated as described for haddock flesh (Abst. 4042, Vol. 23). The total lipid, about 0·6 per cent., consisted of lecithin 35, waxes and alcohols 13, free cholesterol 8, phosphatidyl ethanolamine 7, free fatty acids 6, cholesterol esters 5, inositol lipids 2 and unidentified lipids 21 per cent. The unidentified lipids contained at least 2 types of phospholipins; one type had a fatty acid : glycerol : P ratio approximating to 4 : 2 : 1 and the other had a fatty acid : P ratio of about 4 : 1; its P : glycerol ratio has not yet been determined.

7. Phospholipin fractions from haddock and cod muscle were hydrolysed with KOH. The resulting K salts of phosphate esters from these hydrolysates were fractionated by different methods, including paper chromatography, differential solubility and stability to hydrolysis. These studies revealed the presence of a series of phosphate esters based on glycerol and small amounts of H_3PO_4 in some other combination.

A micro-chromatographic method for the estimation of glycerol was developed and by its application the ethanol-soluble phospholipins were shown to contain phosphate esters with more than 1 glycerol residue per P atom, suggesting bisphosphatidic acid structures.

The acid-periodate oxidation procedure was found to be a completely non-specific method for estimating glycerophosphate in biological material.

JOSHI, S. and MAGAR, N. G. **Nutritive value of some Bombay fish. 3. Phospholipids in fish.** *J. Univ. Bombay*, 1955, **23,** No. 5, 27–33. [Dept. Biochem., Inst. Sci., Bombay.]

See Absts. 4391, Vol. 24; 3363, Vol. 25.

3. Analyses of brain and muscle tissue from 22 different varieties of Bombay fish yielded the following range of data expressed as a percentage of dry weight: total phospholipins, 17·2 to 27·5 and 4·3 to 5·7; amino phospholipins, 14·8 to 29·9 and 3·7 to 5·3; total cholesterol, 4·8 to 8·9 and 0·3 to 0·8; free cholesterol, 4·7 to 9·8 and 0·2 to 1·15; ester cholesterol, 0·1 to 0·4 and 0·11 to 0·34; lecithin, 4·5 to 9·9 and 2·3 to 3·6; cephalin, 6·4 to 13·4 and 0·9 to 2·2; sphingomyelin, 2·4 to 4·3 and 0·2 to 0·6. The water ratio, *i.e.*, wet weight : dry weight, ranged from 3·9 to 4·4 and 4·2 to 4·9.

In contrast to fish muscle, the concentration of lipids in the brain did not vary within individuals of the same species.—A. Hepburn.

SVASTI, K. **The mineral contents of *bilis*, a marine fish of Malaya.** *Philippine J. Sci.*, 1954, **83,** 365–379. [Dept. Chem., Univ. Malaya, Singapore.]

Several species of *Stolephorus* are eaten whole in Malaya under the name of *bilis*, fresh or more commonly dried. *S. pseudoheterolobus* is less than 9 cm. long; it is always on sale in the markets. The whole fish was analysed, fresh, cooked and dried. Statistical analysis of the results showed that the dried fish contained, per 100 g., moisture not less than 29·1, ash 16·6, protein 45·3, Ca 0·98 g. and Fe 8·5 mg. The contribution made to the diet by the fish was compared with different sets of standard allowances, and it was found to be a cheap and common source of protein, Ca and Fe. It contributes P also, but very little fat.—E. M. Hume.

PATHAK, S. P. and DEY, L. M. **The fatty acid composition of Indian turtle fat.** *Biochem. J.*, 1956, **62,** 448–451. [Dept. Indust. Chem., Banaras Hindu Univ., India.]

The component fatty acids of the body fat of an Indian marine turtle (*Erthmochelies imbricata*) were estimated by ester fractionation. The fat was characterised by its high content of unsaturated acids, which accounted for 66·3 per cent. of the total, made up of C_{14} 1·3, C_{16} 12·9, C_{18} 23·9, C_{20} 20·7, C_{22} 4·6 and C_{24} 2·9 per cent. The saturated acids consisted of lauric 0·1, myristic 10·2, palmitic 15·0, stearic 7·2, arachidic 1·1 and behenic 0·1 per cent. of the total acids.—G. A. Garton.

FOLKES, B. F. and YEMM, E. W. **The amino acid content of the proteins of barley grains.** *Biochem. J.*, 1956, **62,** 4–11. [Dept. Botany, Univ. Bristol.]

The 4 chief protein components of barley, albumin, globulin, hordein (prolamin) and hordenin (glutelin), were analysed quantitatively for amino acids. The globulin, and especially the albumin, had an amino-acid composition similar to that of the protoplasmic protein of young barley seedlings

(Abst.1654, Vol. 24), but hordein and hordenin contained much more amide, glutamic acid and proline and less aspartic acid, glycine, lysine and arginine.

ADRIAN, J. Les plantes alimentaires de l'Ouest Africain. 1. Les mils et les sorghos. Valeur alimentaire. Usages. [**Food plants of West Africa. 1. Millets and sorghums. Food values. Uses.**]

ADRIAN, J. and SAYERSE, C. (with OSPITAL, T.) 2. Composition des mils et sorghos du Sénégal. [**2. Composition of millets and sorghums from Senegal.**] Organisme de Recherches sur l'Alimentation et la Nutrition Africaines, Dakar, 1954, pp. 167.

1. The greater part of this monograph (121 pp.) is a review of the literature on agronomy, chemical composition, physiological value, with special reference to amino acid supplementation, and the use in human or animal nutrition of millets (*Pennisetum* spp.) and sorghum. From theoretical considerations a mixture of extracted soya bean flour, milk and yeast, 94, 3 and 3 parts, is proposed as a suitable supplement to a diet of which these cereals are the main constituents.

2. Data are given for analyses of 32 samples of these grains, 17 of sorghum and 15 of millet, of which 21 were from the Agricultural Research Station at Bambey, Senegal and 11 were grown by the local people. The results refer to physical character of the grains, total composition except for fibre content, ash constituents Ca, P, Na and K, 11 amino acids, and vitamin B_1, riboflavin, nicotinic acid and vitamin B_{12}. Cultivation under the better conditions appeared to lead to higher contents of total protein, phenylalanine and threonine, and nicotinic acid in both cereals and of vitamin B_1 in sorghum; there was some evidence that Ca also was increased in millet.

There is as an appendix a reprint of Adrian's technique for estimating amino acids; see Title 4636, Vol. 25. [Some errors have been noted in the bibliography and in the names of authors.]

ROHRLICH, M. and RASMUS, R. Versuche zur chemischen Differenzierung der Eiweiss-stoffe des Weizens und Roggens. 2. Untersuchungen über die Aminosäurezusamensetzung der Eiweiss-stoffe aus Aleuronzellen, Endosperm und Keim von Weizen und Roggen. [**Chemical differentiation of the proteins of wheat and rye. 2. Amino-acid composition of the proteins of aleurone cells, endosperm and germ of wheat and rye.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1956, **103,** 89–96. [Versuchsanst. Getreideverwertung, Berlin.]

For part 1 see Abst 34, Vol. 26.

2. Much of the protein could not be extracted from the aleurone cells of wheat or rye by water, 10 per cent. NaCl, 2 per cent. HCl or 72 per cent. alcohol at room temperature and is therefore assumed to be bound in the cells. Of the total protein of wheat and rye brans, albumin formed 21·3 and 18·1, globulin 13·7 and 16·6 and prolamin 9·8 and 17·0 per cent. Extracts and grain fractions were hydrolysed with 57 per cent. hydriodic acid and subjected to circular paper chromatography with a 4 : 1 : 5 mixture of *n*-butanol, glacial acetic acid and water as solvent and ninhydrin and other reagents for detection; several chromatograms are reproduced. Cysteine, lysine, histidine, arginine, glycine, serine, aspartic acid, glutamic acid, threonine, alanine, proline, tyrosine, valine, methionine, tryptophan, phenylalanine, leucine and *iso*leucine were always found. Germ and bran of wheat, and of rye, differed little in amino acid composition except that germ had a little more cysteine and lysine. Wheat gluten had very little lysine or arginine but was rich in glutamic acid; rye endosperm was rich in glutamic acid and also in arginine. No difference was detected between the amino acid compositions of albumin and prolamin from aleurone cells of wheat and those of rye. Since different fractions of endosperm protein of wheat or rye did not differ in amino acid composition, it was concluded that endosperm protein was an entity.—W. M. Deans.

JA[C]QUOT, R., RAULIN, J., ADRIAN, J. and RERAT, A. Composición y valor alimenticio de las Lágrimas de Job (Lágrimas de San Pedro o trigo Adlay) (*Coix Lacryma-jobi*). [**Composir tion and feeding value of Job's tears grass o- adlay** (*Coix lacryma jobi*).] *Arch. venez. Nutricion,* 1955, **6,** 3–21. [Lab. Bioch. ..., Centre Nat. Recherche Sci., Bellevue ... unc., English and German summaries.

The percentage composition of the grain of Job's tears grass (adlay) is moisture 12·49, ash 1·92, protein 14·98, lipids 7·34, assimilable carbohydrates, mainly starch, 60·40 and indigestible carbohydrates 2·95 ; it compares well with medium French wheat. The bran contains ash 18·04, P 0·097 and Ca 0·194 per cent. and 35·5 per cent. cellulose, which makes it useless for non-ruminants. The protein composition of the grain is much like that of maize ; it is rich in leucine and deficient in other essential amino acids, especially tryptophan and lysine. The vitamin content is comparable to that of other cereals.

In digestibility studies with rats a diet consisting solely of whole flour of Job's tears for 15 days allowed slow growth and positive balances of N, Ca and P. The digestibility was identical with that of wheat, but Ca and P were relatively poorly utilised, perhaps because of a high content of phytic acid. In growth experiments with rats Job's tears was less valuable than wheat, even when supplemented with lysine or methionine. The biological value of the protein was only 20, the lowest of any cereal studied.—D. Duncan.

MARAÑON, L. T., CRUZ, A. O. and TUASON, A. M. **Composition of pili pulp and pili-pulp oil from the fruit of *Canarium ovatum*.** *Philippine J. Sci.*, 1954, **83,** 359–363. [Inst. Sci. Technol., Manila.]

Canarium ovatum, Engl. (Burseraceae), is a tree which bears large nuts surrounded by pulp. The pulp was found to contain 72·8 per cent. moisture. When dried the percentage composition was protein 8·0, ether extract 33·6, crude fibre 3·4, ash 9·2 and carbohydrate by difference 45·8, and the energy value was 533 Cal. per 100 g. The composition resembled that of the flesh of the avocado pear. The amount of extract with different fat solvents was about the same. Physical and chemical constants for the purified oil were established. The iodine number was 72·2. To the glycerides of fatty acids, oleic contributed 56·7 per cent. and linoleic 13·5 ; the rest were saturated.

BABAKHODZHAEV, N. K. Usvoyaemost pishchevogo khlopkovogo masla. [**Digestibility of edible cottonseed oil.**] *Vop. Pitan.*, 1956, **15,** 43–44. [2. Med. Inst. I.V. Stalina, Moscow.]

Cottonseed oil is an important item of human diet in the Central Asian republics. A sample of bottled refined oil from Tashkent had sp. gr. 0·9192, viscosity 48·5, refractive index 1·4728, iodine number 105·1, acid number 0·216 and saponification number 194·3. The organoleptic properties after heating were good.

The digestibility of the oil, in 3-day tests with 3 healthy men, was 95·88 per cent., compared with butterfat, 95·31 per cent. The high digestibility may be due to the high content of unsaturated fatty acids.—D. Duncan.

Other Types

2894

MABROUK, A. F. and BROWN, J. B. **The *trans* fatty acids of margarines and shortenings.** *J. Amer. Oil Chem. Soc.*, 1956, **33**, 98–102. [Dept. Agric. Biochem., Ohio State Univ., Columbus.]

The *trans* fatty acid content of 6 samples of margarine and 5 samples of shortenings was estimated by infrared spectrophotometry. Calculated as trielaidin, the margarines contained from 32·9 to 4·17 per cent. of *trans*-components and the shortenings, with 1 exception, from 22·7 to 36·6 per cent. The exception was a blend of meat and vegetable fats (" Swift'ning ") the *trans*-glyceride content of which was 0·4 per cent.; unlike other fats examined, this blend had not been subjected to hydrogenation.

Methyl esters prepared from 1 sample of shortening and 1 sample of margarine were distilled *in vacuo* and the fractions were analysed by ultraviolet and infrared spectrophotometry. All the fractions contained *trans*-acids, though the largest amounts were present in the C_{18} group of acids; low-temperature crystallisation of the combined C_{18} esters from the margarine sample yielded a fraction containing 90 per cent. of *trans*-acids.

It is concluded that the unsaturated fatty acids of most commercial margarines and shortenings (prepared by hydrogenation of vegetable oils, especially cottonseed and soya bean oils) are an extremely complex mixture of many of the theoretically possible geometric and positional isomers of oleic and linoleic acids. It is estimated that the consumption by the population of the United States is about 1 billion [American] pounds of *trans*-acids per year; preliminary studies on human body fat have shown the presence of *trans* fatty acids.—G. A. Garton.

Pasture, Hay and Silage

2895

BROUGHAM, R. W. **A study in rate of pasture growth.** *Austral. J. Agric. Res.*, 1955, **6**, 804–812. [Grasslands Div., D.S.I.R., Palmerston North, N.Z.]

The experimental design permitted mathematical separation of irregular weather effects from main growth effects. A short-rotation sward of ryegrass and clover was studied during a 9-week period in spring 1953. Growth curves were sigmoid, and during 5 weeks when rate of growth was constant, dry matter production approached 150 lb. per acre daily.—J. L. Corbett.

2896

JOHNS, A. T. **Pasture quality and ruminant digestion. 1. Seasonal change in botanical and chemical composition of pasture.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37**, 301–311. [Grasslands Div., D.S.I.R., Palmerston North, N.Z.]

1. A short-rotation pasture of ryegrass and clover was sampled and then grazed intensively by sheep at short intervals over a 17-month period. Total N, N.P.N., free and bound amino N and soluble carbohydrate in both ryegrass and clovers were estimated. Concentrations of individual amino acids varied widely but bore no relation to season. Similar analyses were also made on a sample of ryegrass to determine variations in composition at different heights from the ground. Estimates of the standard error of the sampling procedure and of chemical estimations are given.—J. L. Corbett.

2897

TODD, J. R. **Investigations into the chemical composition and nutritive value of certain forage plants at medium altitudes in the tropics. 1. Seasonal variation in the chemical composition of the grasses *Bothriochloa insculpta*, *Chloris gayana* and *Brachiaria dictyoneura*, under rotational light grazing, with a note on the persistence of the grasses. 2. The digestibility and nutritive value of three grasses at different stages of growth.** *J. Agric. Sci.*, 1956, **47**, 29–34; 35–39. [East African Vet. Res. Organiz.]

1. Samples were collected at intervals over a year from 3 pairs of plots, each pair carrying, at the beginning of the experiment, a pure stand of one species. The pairs of plots were grazed alternately for 2 weeks by sheep. In 2 cases the stands remained pure; the pair with *Chloris gayana* were invaded by a " couch " grass, *Digitaria scalarum*, about halfway through the period. Crude and true protein, ether extract, fibre, total and acid-soluble ash, Ca, P and K were estimated and, except for Ca and P, the data are tabulated along with the previous month's rainfall.

Protein and P contents were closely associated with rainfall. Fibre remained relatively high even in the vegetative phase. The content of insoluble ash was high and that of P low.

2. Digestibility data from 9 trials with s[illegible]2, are presented. In 5 *Bothriochloa insc*[illegible]dnc.,

different stages of growth was studied, in 2 Rhodes grass (*Chloris gayana*) in early flowering and early dry season stages and in 2 Kikuyu grass (*Pennisetum clandestinum*) in the young vegetative 3-in. stage and in a later 9- to 12-in. vegetative stage.

Bothriochloa insculpta and Rhodes grass were relatively poor in digestive protein. Kikuyu grass had a high digestible protein content in the early stage and maintained it in the later vegetative stage. It resembled British pasture grasses in providing a surplus of protein over starch equivalent for milk production.—D. Harvey.

2898

CURASSON, M. G. Études sur les pâturages tropicaux et subtropicaux. [**Studies of tropical and subtropical pastures..**] *Rev. Élevage méd. vét. Pays trop.*, 1955, **8**, 357–391.

A review. For previous instalments see Title 4301, Vol. 24; *Rev. Élevage méd. vét. Pays trop.*, 1954, **7**, 37; Abst. 294, Titles 2842, 5776, Vol. 25.

2899

HASLER, A. and ZUBER, R. Beitrag zur Kenntnis des Kobaltgehaltes im schweizerischen Wiesenfutter. [**Cobalt content of Swiss pasture.**] *Schweiz. Landwirtsch. Monatsh.*, 1955, No. 5, pp. 11. [Eidg. Agrikulturchem. Versuchsanst., Liebefeld-Berne.]

Cobalt was estimated by a modification of the method of Arthur *et al.* (Abst. 2685, Vol. 23) in 161 samples, mainly of first and second-cut hay of the years 1949, 1950 and 1951, from over 30 farms in the Institute's area. The results are discussed in conjunction with the literature. The Co content ranged from 0·07 to 0·42 p.p.m. of the dry matter, mean 0·16; the results were in good agreement with those from other countries. There was little difference between cuts or between years but considerable difference between farms. Some of the values were low enough to suggest a risk of Co deficiency in livestock, but none was found. In preliminary studies on the plants of an old sown pasture and a poor alpine pasture, grass was found to contain less Co and other minerals than clover and clover less than other pasture plants, and on poor acid soil all had more Co and Mn than on a richer soil. In pot trials with cocksfoot, Fe and Mn were decreased by additional P, but Co was unaffected.—W. M. Deans.

2900

HUNGERBÜHLER, K. and SCHÜRCH, A. Der Einfluss der Düngung auf den Nährstoffertrag einer Magerwiese. [**Effect of manuring on the yield of nutrients from a poor pasture.**] *Schweiz. Landwirtsch. Ztschr. "Die Grüne"*, 1955, No. 17, pp. 3. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

Of 6 plots, each of 0·01 hectare, on a poor pasture on sandy calcareous loam at an altitude of 600 m., 2 were treated in spring with basic slag, potash and 3 kg. ammonium sulphate, 2 had an additional 3 kg. ammonium sulphate, and 2 had nothing at all. The yields some 2 months later in kg. were: dry matter 35, 52, 57; crude protein 3·8, 6·4, 8·8; true protein 3·0, 5·3, 7·1. Grass from the manured plots contained more moisture, but the protein content of the dry matter was higher, 12·5 and 15·5 per cent. crude protein compared with 10·9 for the unmanured plots.—W. M. Deans.

2901

FABRIS, A. and ALBONICO, F. Indagine preliminare sulla composizione chimica dei foraggi dell'Italia meridionale. [**Preliminary study on the chemical composition of forages of southern Italy.**] *Ann. Sper. agrar.*, 1955, **9**, 1115–1130. [Ist. Indust. Agrar. Univ. Naples, Portici.] English summary.

The 38 samples of hay were obtained in 1952 from the provinces of Avellino, Campobasso, Chieti, Teramo, Catanzaro and Pescara. Their botanical composition varied considerably. The range of percentage composition, on dry matter basis [taken from the tables] was ash 6·01 to 14·42, crude protein 7·27 to 17·42, digestible protein 4·16 to 12·89, crude fat 0·73 to 1·75, crude fibre 20·74 to 33·88, N-free extract 43·12 to 55·58, pentosans 11·7 to 22·4, CaO 0·64 to 3·49, MgO 0·17 to 0·80, P_2O_5 0·15 to 0·81 and alkaline earth alkalescence according to Wellmann (Abst. 890, Vol. 1) [the name is given incorrectly] + 19·5 to + 129·5 m. equiv. Lignin was estimated by several methods (see Abst. 2674, Vol. 26).

It was concluded that most of the samples were deficient in protein and P and contained excessive proportions of fibre and lignin. These are ascribed to poverty of the soil, insufficient manuring, washing out of the hay by rain, and late mowing.

D. Duncan.

2902

NEALES, T. F. **Components of the total magnesium content within the leaves of white clover and perennial ryegrass.** *Nature*, 1956, **177**, 388–389. [Dept. Biol. Sci., Wye Coll. (Univ. London), Ashford, Kent.]

Chlorophyll, which was extracted by acetone and estimated spectrophotometrically, was present as 1·13 and 1·18 per cent. on a dry weight basis, 0·219 and 0·199 on a fresh weight basis, in the leaves of white clover and perennial ryegrass. The ratios of chlorophyll a to chorophyll b were 2·88 : 1 and 3·07 : 1. The Mg as chlorophyll, calculated from these ratios and the formulae of the chlorophylls, was 12·86 and 17·75 per cent. of the total Mg in the leaves; in the fibrous material left after extraction it was 62·47 and 53·29 per cent.—A. Hepburn.

[**Relation between losses of dry matter and total butyric acid of ensiled brewer's grains.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag. Prof. Crasemann, 13–16. [Eidg. Landwirtsch. Versuchsanst., Liebefeld, Berne.]

Brewer's grains were ensiled in round concrete silos, 4 each of capacity 5 and 0·8 c.m., and kept for from 4 to 8 months. The losses of weight were from 7·04 to 20·9 per cent. and the butyric acid contents from 0·18 to 0·91 per cent. There was a positive linear relation between loss of weight and total butyric acid content,

$$y = 3{\cdot}01 + 17{\cdot}79\,x,$$

where x was the mean percentage of butyric acid and y the percentage loss of dry matter during ensilage. It was estimated that the loss of dry matter in silage without butyric acid is about 3 per cent.—D. Duncan.

DIJKSTRA, N. D. Over de verteerbaarheid en voederwaarde van verse en geënsileerde zoete lupine. [**Digestibility and feeding value of fresh and ensiled sweet lupins.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.16, pp. 22. [Rijkslandbouwproefstat., Hoorn.] English summary.

Since data were last reviewed (Abst. 5735, Vol. 7) further work has been done abroad and in the Netherlands. Here the assembled results are tabulated and discussed with special reference to the relation of feeding value to chemical composition. In Holland, silage was made at two centres without addition or with 5 per cent. dried ground sugar beet at one and with A.I.V. fluid at the other. That without addition was of relatively poor quality; with sugar beet the quality was excellent, p_H 3·96, no butyric acid, 1·70 per cent. lactic acid, and relatively little loss of crude protein, 19 as against 33 per cent. without addition. The lupin crop from which the sugar-beet silage was made had much less protein than that from which the A.I.V. silage was made and its digestibility was less.

Regression formulae and graphs give the relation of crude to digestible crude protein, and the inverse relation of digestible organic matter to crude fibre. With these, starch equivalent can be computed.

I. Leitch.

3. VITAMINS

GENERAL

2905

LACOURT, A., DELANDE, N. and DEPADUWA, G. Identification spécifique des acides aminés et des vitamines par l'indice de réfraction et la température eutectique. Application à la chromatographie sur papier et au contrôle. [**Specific identification of amino acids and vitamins by refractive index and eutectic temperature. Application to paper chromatography and to identification.**] *Anal. chim. Acta*, 1956, **14**, 100–108. [Serv. Microchim., Univ. Brussels.] English and German summaries.

Values are given for the refractive index of 38 amino acids and 14 vitamins and for the melting-point of a large number of eutectic mixtures. It is considered that sublimation at from 100° to 200° C. in a moist chamber is preferable to elution for the removal of amino acids from paper chromatograms.

[**2. Attempts at prophylaxis by giving different groups of vitamins and organisms of the enteric group.**] *Bol. Ist. sieroterap. milan.*, 1955, **34**, 408–417 ; 418–424. [Ist. Igiene, Univ. Modena.] English summaries.

1. Aureomycin was highly toxic to rabbits. Of 4 weighing 1400 g. and given a daily oral dose of 14 mg. aureomycin per kg. bodyweight, all died between the 14th and the 15th day with great congestion of the organs.

Seven similar rabbits were given aureomycin daily in the same way, and from 3 to 7 days later they were inoculated intravenously with a culture of *Candida albicans*. The result did not differ from that obtained with aureomycin alone. Six similar rabbits, inoculated with the fungus only, lived from 20 to 45 days. They had diarrhoea but no congestion of the organs. Histological examination was made of organs and tissues from all 3 groups.

2. Four rabbits were given aureomycin as just described but only for 3 days, after which the inoculation with *C. albicans* was given. At the same time daily oral administration was started of vitamin B_1 20 mg., riboflavin 0·004 mg., vitamin B_6 0·04 mg., Ca pantothenate 0·08 mg. and extract of liver and yeast 0·8 mg. until the rabbits died from 6 to 16 days after the inoculation with *C. albicans*. They showed severe visceral congestion. Another 4 rabbits were treated in the same way with, in addition, biotin, nicotinamide and vitamins A, D, E, K and C, but the result was not affected. Substitution of a culture of organisms of the enteric group for the vitamins was equally without effect.—E. M. Hume.

SYURINA, N. A. Bor'ba s avitaminozom serebristo-chernykh lisitz v usloviyakh Krainego Severa. [**The control of avitaminosis affecting silver foxes under conditions in the Far North.**] *Karakul. i Zver.*, 1955, **8**, No. 3, 41–42.

Some of the fox farms in the Far North had for 3 to 5 years failed to reach the required standards of production. On the farm studied the ration in 1952 provided 600 to 650 Cal. daily, with half the energy value supplied by deer meat and the rest from groats, fish, milk and supplements of fish oil and sprouted oats to provide vitamin A and vitamins of the B complex.

In 1954 the foxes intended for breeding were given in December supplements of 10 g. hydrolysed yeast, 4 g. vitaminised fish oil and cranberries. When the breeding season began male foxes were given liver, egg powder and vitamin E. Pregnant vixens received 700 to 750 Cal. and supplements of 50 g. deer liver, 12 g. hydrolysed yeast and 4 g. fish oil. Any weak cubs received special care and were given ascorbic acid.

The number of cubs obtained from each vixen rose from 1·4 in 1951 to 4·28 in 1954, and losses of young foxes were reduced.—D. Duncan.

JOYNER, L. P. and DAVIES, S. F. M. **Sulphaquinoxaline poisoning in chickens.** *J. Comp. Pathol.*, 1956, **66**, 39–48. [Vet. Lab., Minist. Agric., Weybridge.]

The effect of age and state of nutrition on the reaction of chickens given sodium sulphaquinoxaline in drinking water as a treatment for coccidiosis was studied. Absorption and excretion of the drug followed different patterns in old and young birds; signs of toxicity were most severe in

birds between 4 and 8 weeks old. In all the birds that died there was fluid in the body cavity, haemorrhages in the muscles, and lesions of the spleen. Clotting was delayed in all the birds receiving the drug and was restored to normal with vitamin K or its analogues. Vitamin K did not prevent other manifestations of toxicity, and dietary supplements or injections of ascorbic acid, vitamin B_1, riboflavin, pyridoxine, pantothenic acid or vitamin A or D did not decrease the incidence of the lesions.—A. M. Copping.

2917

MEKHANIK, F. Ya. O znachenii vitaminov dlya ryb. [**The significance of vitamins for fish.**] *Priroda*, 1955, No. 10, 102–104.

When young rainbow trout were fed on a diet containing 1 part fishmeal, 1 part meat-and-bone meal and 2 parts wheat bran they made only 56 per cent. of the growth of trout fry normally fed on fresh fish. Addition of 20 ml. liver extract and 5 g. baker's yeast per kg. basal diet slightly improved growth, and liver extract and fish liver oil, or yeast and fish liver oil, gave 74 per cent. of normal growth, but all 3 additions were required for full normal growth. The vitamin requirements of fish are not well understood.—D. Duncan.

EHEART, J. F., YOUNG, R. W., MASSEY, P. H. (Jr.) and HAVIS, J. R. **Crop, light intensity, soil pH, and minor element effects on the yield and vitamin content of turnip greens.** *Food Res.*, 1955, **20,** 575–581. [Virginia Agric. Exp. Stat., Blacksburg.]

Yield, dry matter and ascorbic acid content were estimated for turnip greens of a single variety grown on the same ground in the spring and autumn of 1950 and the autumn of 1952; in the last crop, carotene, vitamin B_1 and riboflavin also were estimated. The methods were those of the Southern Cooperative Group ("Studies of sampling techniques and chemical analyses of vegetables", *Southern Coop. Series, Bull.* No. 10, 1951, p. 129). The experiment was of split factorial design, with 72 plots in each year including replications. The conditions studied were: low soil *p*H, 4·8 to 5·1, and high soil *p*H, 6·6 to 6·9, achieved by applying lime; shading and no shading; and application of trace elements (Mn, Cu, Zn, Fe, Mg, Ca and B) by spraying the leaves 2 weeks before harvesting, or as a soil dressing after thinning, or no application of trace elements. Results which were statistically significant are tabulated.

There were considerable variations between the 3 crops, greater than those due to difference in conditions. Yield was favoured by high soil *p*H, dry matter by absence of shading. Contrary to numerous reports in the literature, ascorbic acid content was not significantly affected by light. It was greater in the spring crop than in either of the autumn crops. Carotene content was favoured by shading, vitamin B_1 by trace elements applied to the soil and by a combination of low soil *p*H and no shading, and riboflavin by absence of shading, especially when trace elements were applied to the soil. The mean values found, per g. on a dry basis, were for carotene 665·30 μg., vitamin B_1 14·40 μg., riboflavin 37·45 μg. and ascorbic acid 11·58 mg.; they did not agree with those in the tables of Watt and Merrill (Abst. 4782, Vol. 20), the first 2 in the present study being much higher and the last 2 lower.—W. M. Deans.

2921

BANERJEE, S., ROHATGI, K., BANERJEE, M., CHATTOPADHYAY, D. and CHATTOPADHYAY, H. **Pyridoxine, inositol and vitamin K contents of germinated pulses.** *Food Res.*, 1955, **20,** 545–547. [Dept. Physiol., Presidency Coll., Calcutta.]

In the same 7 pulses as before (see Abst. 3000, Vol. 24), vitamin B_6 and inositol were estimated microbiologically with *Saccharomyces carlsbergensis* (see Abst. 1099, Vol. 13) and vitamin K by the colorimetric oxidation-reduction method of Scudi and Buhs (Abst. 2910, Vol. 11) before and after germination for 2 or 4 days.

The tabulated results, in mg. per 100 g., showed that vitamin B_6 in ungerminated pulses ranged from 0·14 in *Pisum sativum* to 0·65 in *Lathyrus sativus*, and increased on germination considerably in some and to some extent in all but *L. sativus*. Inositol ranged from 70 in *Phaseolus radiatus* to 240 in *Cicer arietinum* and increased on germination in all. Vitamin K ranged from 0·13 in *Phaseolus mungo* to 0·30 in *P. radiatus* and *Cicer arietinum*, and it too increased on germination in all.

W. M. Deans.

BRÆKKAN, O. R. (with HANSEN, K. and SKOGLAND, T.) Vitaminer i norsk fisk. 2. Vitaminer i forskjellige organer fra makrellstørje (*Thunnus thynnus*) fanget utenfor Norges vestkyst. [**Vitamins in Norwegian fish. 2. Vitamins in**

some organs of tunny (*Thunnus thynnus*) caught off the west coast of Norway.] *Fiskeridirektoratets Skr. Ser. Teknol. Undersøk.*, 1955, **3**, No. 3, pp. 18. English summary.

For part 1 see Abst. 4313, Vol. 24.

Literature is reviewed. The samples of organs were taken at gutting from about 100 fish, and of muscle as the fish were prepared for freezing experiments, from 4 or 5 fish, except for neck muscle. Nicotinic acid, riboflavin, pantothenic acid and vitamin B_{12} were estimated by microbiological methods, vitamin B_1 by the thiochrome method, vitamin A by spectrophotometry with conversion factor 1900, dry matter by oven drying, fat as Soxhlet ether extract, ash by incineration, and N by macro-Kjeldahl. There were 3 series of samples from fish of different sizes. The tables give means for the series separately and together, for muscle, liver, pyloric caeca, stomach, intestine, spleen, kidneys, heart (auricle and ventricle separately), gills, roe and milt (both immature).

Dry matter varied with fat both when organs and when series of fish were compared. Vitamin contents in μg. per g. for muscle and liver, respectively, were for pantothenic acid 4·4 and 25·4, nicotinic acid 84·4 and 88·0, riboflavin 1·0 and 44·8, vitamin B_{12} 0·037 and 3·53, vitamin B_1 2·10 and 4·17. Vitamin A in I.U. per g. was in liver from 6700 to 22,500, mean 13,400, and in neck muscle 10, pale fillet 30 and dark fillet 35. The vitamin A value for muscle and the vitamin B_{12} value for liver were outstandingly high.—I. Leitch.

VITAMIN A

2923

DUBOULOZ, P. and MARTINET, H. Sur le dosage biologique de la vitamine A au moyen du poussin. 1. Recherches préliminaires. [**Biological estimation of vitamin A with chicks. 1. Preliminary research.**] *Ann. Zootech.*, 1955, **4**, 201–213. [Lab. Phys., Fac. Méd., Marseilles.]

Day-old Rhode × Sussex chicks were given a diet deficient in vitamin A. Curves were constructed of the growth response by groups of male birds to graded prophylactic doses of the vitamin. In general, weight increase reflected increase of the dose; the average weight of groups of 10 birds after 45 days was 338 g. with 10 I.U., 424 g. with 20 I.U. and 459 g. with 40 I.U. Tests in which therapeutic doses were given to birds deprived of vitamin A were unsatisfactory because of the high mortality, which was not reduced by giving penicillin. A tentative method is described for estimating vitamin A activity in feeds. Results were not entirely satisfactory because of the lack of uniformity among the animals normally available. It is hoped to produce an improved method.

SCHOCH, H. Über die Methodik der Karotinbestimmung. [**Technique for estimating carotene.**] *Schweiz. Landwirtsch. Monatsh.*, 1956, No. 1, Sonderheft 60. Geburtstag. Prof. Crasemann, 85–88. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

Carotene was extracted from materials having a low fat content, with a cold mixture of ether and light petroleum. Aluminium oxide standardised by Brockmann's method, a mixture of magnesium oxide and diatomaceous earth, and a mixture of aluminium oxide with sodium sulphate were tested as adsorbents. The first was preferred, with a 1 : 1 mixture of benzene and light petroleum as developing solvent. It was necessary that the moisture content of the aluminium oxide should not exceed 2 per cent. It is considered that the different biological activities of the *cis*- and *trans*-forms of β-carotene might make it advisable to estimate only the *trans*-form.—V. H. Booth.

2926

KALER, H. A. **Determination of carotene in dehydrated alfalfa meal treated with *N*, *N'*-diphenyl-*p*-phenylenediamine.** *J. Agric. Food Chem.*, 1956, **4**, 70–71. [National Alfalfa Dehydrating and Milling Co., Lamar, Colo.]

For extraction and chromatography the A.O.A.C. method was followed for estimating carotene in alfalfa meal. Five ml. of stannous chloride reagent were added to the eluate which was then made up to 100 ml. in the standard manner, and the density was read within an hour on the spectrophotometer. The reagent was freshly prepared each day by dissolving 0·1 g. $SnCl_2 . 2H_2O$ in 50 ml. ethanol.

Solutions of carotene eluates, with and without *N*, *N'*-diphenyl-*p*-phenylenediamine, and stannous chloride had closely similar spectral absorption curves, which showed that the reagent had no effect on carotene, but destroyed all the pigment

formed by reaction between the diamine and the magnesia used for chromatography in the A.O.A.C. method.—V. H. Booth.

2927

MOFFITT, R. A. and MEHL, J. W. **Comparison of the phasic and chromatographic methods for analysis of carotene in dehydrated alfalfa.** *J. Assoc. Off. Agric. Chem.*, 1956, **39,** 255–259. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles 7.]

When " carotene " from alfalfa is estimated by the phasic and by the chromatographic method, the results may be up to 25 per cent. higher by the phasic method. The nature of the pigments included as " carotene " by the former method, but excluded by the latter, was studied. An extract from dehydrated alfalfa was purified by the phasic method and then chromatographed on MgO. The β-carotene was removed with 3 per cent. acetone, after which the remaining pigments had separated into 4 zones. The column was extruded and dissected, and the 4 coloured zones were eluted separately into carbon disulphide. The pigment from the 4 zones was compared spectrophotometrically and chemically with known pigments and identified from the top of the chromatogram downwards as " xanthophylls " that had not been removed by the phasic separation, zeaxanthol or a similar pigment or pigments, *neo*-β-carotene B, and *neo*-β-carotene U. When the experiment was repeated with an extract from fresh alfalfa, the 2 lowest zones of pigment did not appear, and it is supposed that those 2 pigments had been formed by isomerisation during dehydration of the alfalfa.—V. H. Booth.

The synthesis of 3: 4: 3′: 4′-bisdehydro-β-carotene and 3: 4-monodehydro-β-carotene.**] *Helv. chim. Acta*, 1956, **39,** 249–259; 259–273; 274–282. [Lab. F. Hoffmann-La Roche and Co., Basle.] English summaries.

1. The commercial synthesis of β-carotene is described.

The synthetic β-carotene was compared with natural β-carotene for melting-point, elementary analysis, shape of crystals, and other characteristics. Each chemical and physical constant studied was the same for both compounds; the biological values also were the same. Very large doses of the synthetic carotene had no toxic effect on rats or rabbits. Absorption curves in infrared light for β-carotene and some related compounds are given and photomicrographs of their crystals are shown in colour.

2. Detailed methods are given for the preparation of C_{19}-aldehydes that could be used for the synthesis of new carotenoids.

3. Synthesis of two new dehydrocarotenes and some related compounds is described. Absorption curves in visible light and in the infrared region, melting-points, and other characteristics of the two carotenes are given. In growth tests with vitamin-A-depleted rats, the bisdehydrocarotene had 38 per cent., and the monodehydrocarotene 75 per cent., of the activity of β-carotene.—V. H. Booth.

FRANK, S. **Carotenoids.** *Sci. Amer.*, 1956, **194,** 80–86. [Washington Square Coll. Arts Sci., Univ. New York.]

An illustrated, semi-popular article discusses the theory that the function of carotenoids in green leaves is to provide the phytol moiety for the biosynthesis of chlorophyll.

The spectral absorption maxima of protochlorophyll, a precursor of chlorophyll, were at the same wavelengths as those most effective in reducing the content of carotenoids in leaves and in promoting synthesis of chlorophyll. When seedlings were germinated and grown in the dark, no chlorophylls were produced but carotenoids increased. When green plants were removed to the dark, the chlorophylls soon disappeared but there was no increase in carotenoids. It is suggested, therefore, that the biosynthesis is not reversible, carotenoids not being produced by the degradation of chlorophyll.—V. H. Booth.

2931

CURL, A. L. and BAILEY, G. F. **Orange carotenoids. 1. Comparison of carotenoids of Valencia orange peel and pulp. 2. Carotenoids of aged canned Valencia orange juice.** *J. Agric. Food Chem.*, 1956, **4,** 156–159; 159–162. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 10, Calif.]

1. The pulp and peel of California Valencia oranges obtained in May were separately extracted with acetone and the pigments were transferred to light petroleum. Pulp and peel yielded total carotenoids approximately equivalent to 24 and 98 p.p.m., respectively, on the basis of colorimetric equivalence with β-carotene. The peel, after storage for 4 months at 6° C., yielded 34 p.p.m., a retention of 35 per cent. The carotenoids in each solution were examined in detail by counter-current distribution between light petroleum and 99 per cent. methanol, by chromatography on magnesia, and by spectrophotometry.

The 24 pigments from pulp and peel are identified or described as "like" a known carotenoid. The pigments in pulp and peel were qualitatively similar though quantitatively different. Phytofluene, luteoxanthins, auroxanthin and cryptoxanthin together made up nearly half the total carotenoids in pulp. Violaxanthin accounted for nearly half the carotenoids in fresh peel, with luteoxanthins making a considerable contribution. Carotenes, including α- and β-, were present in small amounts in both pulp and peel. One constituent found in early-season (May) pulp and peel, but not found in late-season (autumn) orange juice, was cryptoxanthin furanoxide.

2. Carotenoids from canned juice which had been stored for 3 years at room temperature were similarly examined for comparison with those from fresh juice. Twenty-seven carotenoids are listed. Zeaxanthin and mutatoxanthins made up nearly half the total. Epoxides had disappeared, the diether diol fraction was reduced, and furanoxides had increased. There had been no significant hydrolysis of esters during storage. There was no evidence of more than a small degree of isomerisation to *cis*-forms.—V. H. Booth.

GRANGAUD, R. and MASSONET, R. Recherches sur la biogénèse de la vitamine A des poissons. 1. L'astaxanthine, provitamine A pour *Gambusia holbrooki* Grd. **[Biogenesis of vitamin A in fishes. 1. Astaxanthin, provitamin A for *Gambusia holbrooki*, Grd.]** *Arch. Sci. physiol.*, 1955, **9**, 245–256. [Lab. Chim. Biol., Fac. Méd., Algiers.]

The advantages of the tiny carnivorous fish *Gambusia holbrooki*, Grd., as experimental animal for feeding studies are detailed. A group of the fishes was maintained on a vitamin-A-deficient diet of potato flour or white breadcrumbs, casein, yeast, and vitamin D. After 35 days, when some were killed, no vitamin A could be detected in the whole fish or in the organs including the eyes. The food of the others was then supplemented with tissues from *Aristeus antennatus*, devoid of vitamin A and carotene, or with astaxanthin prepared from those crustaceans and dissolved in oil. After 26 days the fishes were killed, and vitamin A was found, by the Carr Price test, almost entirely in the eyes. Similar results were obtained in several other experiments.

It was concluded that astaxanthin is a provitamin A for *Gambusia*. The possibility that vitamin A_2 is produced from the enolic form of astaxanthin is discussed.—V. H. Booth.

2933

GRANGAUD, R. and MASSONET, R. Conversion de l'astaxanthine en vitamine A chez *Gambusia holbrooki* Grd. **[Conversion of astaxanthin to vitamin A in *Gambusia holbrooki*, Grd.]** *C.R. Acad. Sci.*, 1955, **241**, 1087–1089.

GANGULY, J., KRINSKY, N. I. and PINCKARD, J. H. **Isolation and nature of echinenone, a provitamin A.** *Arch. Biochem. Biophys.*, 1956, **60**, 345–351. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

The pigment obtained from 4000 sea urchins, *Strongylocentrotus purpuratus* and *S. franciscanus*, was purified by repeated column chromatography followed by crystallisation, to yield orange-red crystals of m.p. 179° to 181° C. Absorption maxima were at 458 mμ. in light petroleum, 490 to 496 mμ. in carbon disulphide and 472 to 478 mμ. in chloroform. The values agreed closely with those published for echinenone by Goodwin and Taha (Abst. 3326, Vol. 20), who obtained it from limpets, *Patella vulgata* and *P. degressa*. The oxime of echinenone had an absorption maximum at 455 mμ. in light petroleum. Reduction with aluminium *iso*propoxide and lithium aluminium hydride yielded the corresponding alcohol, *iso*-cryptoxanthin. An authentic sample of *iso*-cryptoxanthin was converted by the Oppenauer oxidation to echinenone; it had properties identical with those of the pigment isolated.

FISHER, L. R., KON, S. K. and THOMPSON, S. Y. **Vitamin A and carotenoids in certain invertebrates. 4. Mollusca: Loricata, Lamellibranchiata, and Gastropoda. 5. Cephalopoda.** *J. Marine Biol. Assoc. U.K.*, 1956, **35**, 41–61; 63–80. [Nat. Inst. Res. Dairying, Univ. Reading.]

For previous parts see Absts. 308, Vol. 24; 1660, Vol. 26.

4. Vitamin A, total carotenoids and β-carotene were estimated in 18 species of gastropods, 9 of lamellibranchs and 1 of loricates. Specimens were preserved by immersion in boiling sea-water for 2 min. and then in absolute alcohol. Later, in

the laboratory, they were saponified and extracts were purified chromatographically. Interference by xanthophylls, when vitamin A was estimated by the $SbCl_3$ reaction, was reduced by passing the extract in *n*-hexane through an alumina column treated with 8 per cent. ethanol in hexane before passing it through a column of untreated alumina. The vitamin A value in μg. per g. whole body was for *Mytilus edulis* 0·51, *Ostrea edulis* 0·26, *Gryphaea angulata* 0·16, *Cardium edule* 0·16, *Mya arenaria* 0·02, *Patella vulgata* 0·19, and *Aplysia depilans* 0·11. No vitamin A was found in *Chlamys septemradiatus*, *Pecten maximus*, *Scrobicularia plana*, *Buccinum undatum*, *Clione limacina*, *Astrea undosa*, *Helix aspersa*, *Littorina littoralis*, *L. littorea*, *L. rudis* or *Murex trunculus*. Ten specimens of a loricate, *Stenoplax conspicua*, gave average values in μg. per g. for vitamin A 0·044, carotenoids 5·1 and β-carotene 0·41.

Species containing vitamin A were further examined, and the vitamin was found mainly in the digestive glands or viscera. In *Patella vulgata* the concentration of vitamin A and carotenoids was higher in the testis, 0·67 and 112 μg. per g., respectively, than in the ovary, 0·11 and 19. In *Patella* evidence was obtained that vitamin A is produced by the conversion of carotenoid precursors in the algal diet. Possible functions of vitamin A in the different species are discussed.

5. Vitamin A, fat and carotenoids were estimated in 10 species of cephalopod including 4 squids, 5 cuttlefish and 1 octopus. Specimens were preserved in alcohol until analysis, when they were saponified and the extracts purified chromatographically. Most tissue extracts were rich in sterols which had to be removed. The extract in light petroleum was evaporated to dryness, dissolved in methanol and kept at — 20° C. for 1 hr., when most of the sterols were precipitated. Vitamin A was found in all the species examined; carotenoids also occurred, but generally only in small amounts. Cuttlefish and octopus were richer in carotenoids than squids. The eyes of *Alloteuthis media* had 0·61 μg. vitamin A per g. and the ovaries 0·71. Eyes of *Loligo forbesi* had from 0·06 to 0·43 μg. vitamin A per g. Livers from the same species had from 0·96 to 16 μg. vitamin A per g. Livers of *Ommastrephes pteropus* had per g. 6·6 and 15 μg. vitamin A and 13 and 42 μg. carotenoids. Other species found to contain vitamin A were *Todaropsis eblanae*, *Sepia officinalis*, *Parasepia elegans*, *Rossia macrosoma*, *Sepietta oweniana*, *Sepiola* sp. and *Eledone cirrosa*.

The form of the vitamin also was investigated in a number of instances. The vitamin was present mainly as the ester, especially in the liver. The reserves of females were depleted by development of eggs, which were found to be rich in vitamin A alcohol. In 2 species, *Loligo forbesi* and *Ommastrephes pteropus*, retinene was isolated from the eyes, which suggests a visual cycle resembling biochemically that of vertebrates.—I. M. Sharman.

HIGH, E. G. **Further antioxidant studies concerned with the metabolism of carotene and vitamin A.** *Arch. Biochem. Biophys.*, 1956, **60**, 456–462. [Dept. Biochem., Meharry Med. Coll., Nashville, Tenn.]

Rats were given a basal diet deficient in vitamin A and daily supplements of 34 μg. carotene or 13 μg. vitamin A with or without one of certain anti-oxidants. The supplements were given for 21 days and faeces were collected for estimation of carotene, after which the rats were killed and vitamin A was estimated in the liver and kidneys. A daily supplement of 10 mg. 2 : 6-di*tert.*butyl-4-methylphenol significantly decreased the deposition of vitamin A from carotene in the liver from an average of 86 to 26 μg., but increased deposition in the kidneys from an average of 2·5 to 7·2 μg. There was no significant difference in growth rate. N, N′-diphenyl-*p*-phenylenediamine had little effect on carotene utilisation but *d*-α-tocopherol decreased deposition of vitamin A in the liver from 80 to 33 μg. and increased it in the kidneys from 4·7 to 7·0 μg. The Wistar strain of rats appeared to excrete less carotene than the Holtzman strain. None of the anti-oxidants had a significant effect on carotene excretion.—R. J. Ward.

2937

IRVING, J. T. and RICHARDS, M. B. **The protective action of vitamin A upon various tissues in the avitaminotic rat, and the sensitivity of these tissues to vitamin A deficiency.** *Brit. J. Nutrition*, 1956, **10**, 7–14. [Joint Dent. Res. Unit, Counc. Sci. Indust. Res., Johannesburg.]

Rats were restricted from a week before weaning to a diet deficient in vitamin A with or without small doses of the vitamin. After periods of up to 250 days they were killed and histological studies were made on the nasolachrymal duct, medulla oblongata, incisor teeth and maxillary fundic alveolar bone.

When no vitamin had been given, degenerative changes were found after 28 days in the medulla oblongata and in the epithelium of the nasolachrymal duct, but not in the two hard structures. When doses of from 0·33 to 3 I.U. daily were given for 50 days, the medulla oblongata, fundic bone and incisor teeth were protected by 1 I.U., but 3 I.U. were required to protect the nasolachrymal duct. In experiments lasting for up to 250 days 2 I.U. daily protected the medulla oblongata and fundic bone; 4 I.U. were needed to protect the nasolachrymal duct. The incisor teeth were not protected by 2 I.U., were partly protected by 4

I.U., but not completely even by 16 I.U. It appears that the requirement of vitamin A is not a function of bodyweight, but should be based on protection of the tissue which is most sensitive to deprivation of vitamin A. The relative sensitivity of the tissues to deficiency depends upon age.

LEUTZKIĬ, K. M. and LYUBOVICH, E. N. Narusheniya v obmene kholesterina pri nedostatochnosti vitamina A. [**Breakdown of cholesterol metabolism in vitamin A deficiency.**] *Dokl. Akad. Nauk SSSR*, 1955, **104,** 280–282. [Chernovitzk. Gosud. Univ.]

White rats initially weighing about 50 g. were given a synthetic diet without vitamin A for from 2½ to 3 months, or for 4 months to produce severe deficiency. Total cholesterol was estimated in the brain, liver, kidneys, adrenal glands, urine and faeces. The cholesterol content of the brain, adrenal glands and kidneys was appreciably less in deprived than in non-deprived animals. The latter excreted significantly less cholesterol in the faeces. More *p*-aminobenzoic acid was acetylated by deprived than by non-deprived rats.

AVDEEV, I. M. and VOROB'EV, A. E. Zabolevanie glaz u telyat na pochve avitaminoza. [**Ophthalmia in calves due to vitamin deficiency.**] *Veterinariya*, 1955, **32,** No. 2, 73–74. [Bzyansk Intersovkhoz Vetbaklab.]

Ophthalmia in calves was found to be caused by deficiency of vitamin A. All the calves were given vitaminised fish oil and separated milk, and the sick ones were given whole milk as well. As a result all the sick calves recovered and ophthalmia disappeared.—H. Scherbatoff.

2940

O'DONOGHUE, J. G. **Vitamin A deficiency in beef cattle.** *Canad. J. Comp. Med.*, 1955, **19,** 367–372. [Vet. Serv. Branch, Alberta Dept. Agric.]

Vitamin A deficiency in cattle, as seen by the author in Alberta, appeared in 3 forms. The first was in young weak calves, which suffered from scouring and sometimes from secondary infections. The second appeared in older animals with damage to the peripheral nervous system which gave rise to inco-ordination. The third affected yearling beef animals which, without inco-ordination, suddenly became blind through injury to the optic nerve.

LUCAS, A., QUINCHON, C., FEUGEAS, C., HENRY, M., GOURDON, J. M., GOURDON, R. and TOUCAS, L. Kérato-conjonctivite, manifestation d'avitaminose A dans un troupeau de moutons. [**Kerato-conjunctivitis, a manifestation of vitamin A deficiency in a flock of sheep.**] *Rec. Méd. vét.*, 1955, **131,** 665–669. [Lab. Central Recherches Vét., Alfort.]

In a flock of 100 sheep, about 50 suddenly, within the space of 3 weeks, showed bilateral corneal opacity with other ocular signs of vitamin A deficiency. They appeared to be blind. The sheep had been kept in stall for about 10 weeks with a diet of beet, fine straw, legume meal of poor quality and a little grain. Specimens from the eyes showed no rickettsiae, and the condition was not infectious. The sheep were given good lucerne hay and, daily for 5 days, 2 ml. oil containing 3000 I.U. vitamin A per ml. The eyes quickly became clear and the sheep could see again. The previous dietary history was not known.

HARVEY, J. D., PARRISH, D. B. and SANFORD, P. E. **The application of deutectomy for reducing initial vitamin A reserves in newly hatched chicks, and some observations on the apparent consumption of these reserves.** *Poultry Sci.*, 1955, **34,** 1314–1321. [Dept. Chem., Kansas Agric. Exp. Stat., Manhattan.]

White Leghorn hens were given a diet low in carotenoids and adequate or inadequate in vitamin A. The progeny were maintained for 8 weeks on a basal diet lacking or supplemented with vitamin A. As judged by survival time, initial vitamin A stores in deutectomised chicks, *i.e.*, chicks from which the yolk sac had been removed, were about 3/4 of those in intact birds when the maternal diet had been adequate in vitamin A. Deutectomy therefore increased the sensitivity of chicks to subsequent treatment in experiments with vitamin A. The effect of removing the yolk sac was less marked when the maternal diet had been low in vitamin A. Variation between individuals in initial vitamin A reserves was reduced to a greater extent by the operation than by restriction of vitamin A intake by the parent hen. Transfer of vitamin A from the yolk to the body was rapid; only 10 per cent. of its initial value was present in the yolk 7 days after hatching. The liver reserves of vitamin A decreased considerably, particularly in deutectomised chicks, during the first 2 weeks after hatching, in spite of a dietary intake of from 1000 to 2000 I.U. vitamin A per lb. feed. On the same diet liver storage was resumed after 2 weeks, in both intact and treated birds.

2944

HARVEY, J. D., PARRISH, D. B., SANFORD, P. E. and HUGHES, J. S. **The utilization of carotene and vitamin A by chicks during the first week after hatching.** *Poultry Sci.*, 1955, **34**, 1348–1357. [Dept. Chem., Kansas Agric. Exp. Stat., Manhattan.]

When carotene was given in aqueous or oily medium, or as alfalfa, to newly hatched chicks from which the yolk sac had been removed, from 65 to 100 per cent. of it appeared to have been absorbed, though some destruction may have occurred in the alimentary tract. Aqueous preparations were better utilised for liver storage and for survival than oily preparations. Pre-formed vitamin A was more effective than carotene when given in similar preparations. Carotene or vitamin A given in oil or in aqueous dispersion or as alfalfa, during periods terminated 6 and 12 hr. after hatching, increased the liver reserves of vitamin A, estimated at 4 days of age, and prolonged the survival of chicks on a diet without vitamin A. Carotene and vitamin A injected into the residual yolks of newly hatched chicks disappeared rapidly; about 35 per cent. of it appeared in the liver. The survival of the chicks also was prolonged. It is tentatively suggested that conversion of carotene to vitamin A may have occurred in the yolk sac. The results showed that the chick converted carotene to vitamin A within 24 hr. after hatching, and that dietary vitamin A was used to support physiological functions involving vitamin A at least by the 5th day and probably earlier.

E. M. Cruickshank.

2945

LAUGHLAND, D. H. and PHILLIPS, W. E. J. **The utilization of vitamin A by normal and deuterectomized chicks.** *Poultry Sci.*, 1955, **34**, 1359–1362. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

Day-old chicks were given a basal diet lacking vitamin A, alone or supplemented with vitamin A acetate or β-carotene. The vitamin A content of the liver was estimated at weekly intervals from 8 to 29 days of age. In chicks having the basal diet alone, the vitamin A content of the liver decreased from 74 I.U. after 8 days to 7·1 I.U. after 29 days. When the diet was supplemented with vitamin A acetate, the content, compared with that of the liver of birds given no supplement, was significantly greater, 232 I.U. after 8 days and 2130 I.U. after 29 days. In chicks given β-carotene, no significant storage occurred within 15 days, but after 29 days there was a rise to 398 I.U. Similar results were obtained with chicks from which the yolk sac had been removed, though storage was less. There was no significant difference between the weight gain of chicks having the basal ration alone and of those receiving supplements. It is concluded that absorption of vitamin A and conversion of β-carotene to vitamin A can occur in chicks less than 2 weeks old.—E. M. Cruickshank.

2946

BRÜGGEMANN, J. and TIEWS, J. Zur Prüfung des Resorptionsumfanges von Vitamin A aus stabilisierten Vitamin A-Konzentraten mit Hilfe des Vitamin A-Leberspeicherungstestes. **[Absorption of vitamin A from stabilised concentrates of vitamin A estimated by measuring storage of vitamin A in the liver.]** *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 20–32. [Inst. Physiol. Ernährung Tiere, Univ. Munich.] English summary.

Rats deprived of vitamin A were given single oral doses of from 450 to 8000 I.U. of commercial preparations of vitamin A; they were killed 96 hr. later and the vitamin A stored in the liver was estimated. The amount stored divided by the quantity given, *Resorptionsindex*, was taken as the measure of utilisation for a preparation. Fourteen preparations were examined with alleged potencies ranging from 450 to 325,000 I.U. per g. Average values for the *Resorptionsindex*, based on estimations with three different intakes, usually 1000, 2000 and 3000 or 4000 I.U., ranged from 20·1 to 59·3. Powdered concentrates were superior to an oily standard preparation though none of them reached the value for the vitamin A emulsion A-Mulsin.—I. M. Sharman.

2947

KRISHNAMURTHY, S. and GANGULY, J. **Effect of blocking the reticulo-endothelial system on the storage of vitamin A ester and alcohol in the liver of the rat.** *Nature*, 1956, **177**, 575–576. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Male rats, fed on a diet low in vitamin A, were divided into 3 groups each of 6 animals weighing between 75 and 100 g. One group remained on the diet alone, and another was given intraperitoneal injections of 1 ml. normal saline daily for 7 days and a single oral dose of 3000 μg. vitamin A in oil on the last day of the injections. The third group was treated like the second except that 1 ml. of a 20 per cent. suspension of Indian ink in normal saline was used instead of saline alone. The rats were fasted for 24 hr. after their last injection and then bled to death by puncture of the heart. The deprived rats were killed in the same way, and vitamin A alcohol and ester were estimated in the plasma and liver of all the animals.

Average values for total vitamin A ester and alcohol in the liver were 2238 and 56 μg. for those given vitamin A without Indian ink, and 1168

and 54 μg. for vitamin A with Indian ink. Corresponding values for the blood in μg. per ml. were 1·9 and 1·2 and 5·1 and 1·9. The low concentration of the ester in the liver and the high value in the blood of the rats treated with Indian ink compared with those given saline alone showed that blocking the Kupffer cells interfered with storage of the ester in the liver. Values for vitamin A alcohol in the liver were scarcely affected, which suggested that there are different mechanisms for storing the two forms of the vitamin.—I. M. Sharman.

2948

EAYRS, J. T. **The effect of vitamin A on the development of hypothyroid rats.** *J. Neuropathol. Exp. Neurol.*, 1956, **15**, 93–102. [Dept. Anat., Univ. Birmingham.]

Of 92 rats in 3 approximately equal groups, 2 groups were made hypothyroid by injection of methyl thiouracil daily from the day of birth, and one of them was given 100 I.U. vitamin A daily. The third group was kept as normal control. During the first 24 days mortality was high among the hypothyroid animals and vitamin A did not reduce it, but the bodyweight and size of the brain of survivors were greater in those given vitamin A than in those not given it. On the 24th day intracranial pressure in the surviving rats was measured; a steady mean pressure of 7·2 mm. Hg was recorded for the normal rats, 5·6 mm. for the untreated hypothyroid animals and 7·0 for the hypothyroid animals given vitamin A. The hypothyroid rats given vitamin A also had a greater axon network density than the untreated hypothyroid animals, and the mean length of the dendrites was 63·8 μ. for the animals given vitamin A, 47 for those without vitamin A and 77·1 for the normal animals. The age when the placing reflex appeared, which is usually retarded in hypothyroidism, was advanced by vitamin A, but not significantly.—I. M. Sharman.

2949

SERFATY, A. and OLIVEREAU, M. Avitaminose A, thyroïde, hypophyse et croissance pondérale chez le rat blanc male. [**Vitamin A deficiency, thyroid, anterior pituitary and growth in weight in the male white rat.**] *J. Physiol., Paris*, 1955, **47**, 829–834. [Lab. Physiol. Gén., Fac. Sci., Toulouse.]

Young male rats were kept on a diet deficient in vitamin A until depletion was indicated by loss of weight and xerophthalmia. They were then killed, and histological studies were made of their thyroid and pituitary glands. The beta cells of the pituitary were found to have degenerated, and the thyroid was atrophied.—T. Moore.

FELL, H. B. **Recent research on vitamins. Effect of excess vitamin A on organized tissues cultivated in vitro.** *Brit. Med. Bull.*, 1956, **12**, 35–36; 37. [Strangeways Res. Lab., Cambridge.]

2951

HERBERTSON, M. A. **The reversibility of the effect of hypervitaminosis A on embryonic limb bones cultivated *in vitro*.** *J. Embryol. Exp. Morphol.*, 1955, **3**, 355–365. [Strangeways Res. Lab., Cambridge.]

Rudiments of limb bone from 6- to 7-day-old chick embryos were cultivated first in a medium which included fowl plasma containing added vitamin A, and subsequently in the same medium but with normal fowl plasma. The fortified plasma contained from 2000 to 4000 I.U. vitamin A per 100 ml., and the normal plasma from 200 to 300 I.U. The excess of vitamin A stopped growth of the explants, and caused the cartilage matrix to shrink and lose its basophilia and metachromasia; the extent of the damage depended on the length of exposure, the stage in development of the rudiment when explanted, and the particular rudiment treated. In the medium containing normal fowl plasma, the degree of recovery decreased with the severity of the injuries which had been sustained. In the shaft the abnormal changes were arrested, but lost matrix was not restored. The cells appeared healthy but resembled osteoblasts more than normal hypertrophic chondroblasts. The epiphyses also recovered partially and began to enlarge again, with a mitotic rate higher than in normal controls.

2952

MCDOWELL, A. K. R. **Variations in the carotene and vitamin A contents of herd butterfats throughout lactation.** *J. Dairy Res.*, 1956, **23**, 111–119. [Dairy Res. Inst. (N.Z.), Palmerston North.]

Samples of butterfat were prepared by melting and decantation from butter made specially on the institute farm and from factory butter. Carotene and vitamin A were estimated in the butterfat so obtained, and the results were studied in relation to the feed of the cow and the period of lactation. The average carotene content of butterfat from 8 Friesian cows which had calved in the New Zealand autumn, April or May, rose from 7·7 μg. per g. in June to 11·2 in August, after which it fell fairly regularly to 7·1 in February. For 16 Jersey cows the corresponding values were 9·8 in June, 12·3 in August and 9·0 in January. Vitamin A values in the groups did not vary much, ranging from 10·3 to 12·4 for the Friesians and from 7·5 to 8·5 for the Jerseys. The carotene content of

butterfat from cows calving in spring followed a similar pattern in each of the seasons investigated, being generally at a maximum in spring and declining to low values in summer. Individual results, considered in relation to the carotene available in the diet, showed that the carotene content of the butterfat was influenced more by the diet than by the stage of lactation. Changes in vitamin A content were relatively small throughout lactation. In some instances a small increase attributed to season occurred in autumn. The content of carotene and vitamin A in butterfat made from milk during the first 12 days after parturition was generally higher than subsequently.—I. M. Sharman.

2953

SCOTT, W. G. and TAYLOR, R. J. **The vitamin-A and carotene potency of national (household) butter determined by a chromatographic-ultraviolet spectrophotometric method of assay.** *Analyst*, 1956, **81**, 117–121. [Govt. Lab., Clements Inn Passage, London, E.C.2.]

Carotene and vitamin A were estimated in 106 samples of imported butter and 10 samples of English butter by the chromatographic method of Boldingh and Drost (*J. Amer. Oil Chem. Soc.*, 1951, **28**, 480) for the analysis of margarine. A sample of 10 g. was saponified, the unsaponifiable matter was dissolved in light petroleum and the solution was chromatographed. The extinction of the carotene fraction, which was eluted before the vitamin A, was measured at wavelengths near 446 mμ. The vitamin A fraction was examined subsequently by measuring the extinction at wavelengths near 324 mμ. From the extinction values the biological potencies were calculated. The tests were made at two different laboratories and there was, in general, good agreement between their results. For the imported butter the vitamin A value ranged from 11·5 to 33·3 I.U. per g., mean 23·9, and the carotene value from 3·5 to 15·2 I.U. per g., mean 9·8. Corresponding values for English butter ranged from 17·7 to 23·4, mean 21·2, and from 4·0 to 9·4, mean 7·2.—I. M. Sharman.

2954

PRADHAN, S. K. and MAGAR, N. G. **Vitamin A_1, A_2 and neo-vitamin A in shark-liver oils.** *Indian J. Med. Res.*, 1956, **44**, 11–20. [Dept. Biochem., Inst. Sci., Bombay 1.]

Oil was extracted from the livers of 6 species of shark; vitamin A and iodine number were estimated. Extracts were purified by chromatography and their spectra were measured in pure *cyclo*hexane and ethanol with a Beckman spectrophotometer; measurements were made also in the product of the $SbCl_3$ reaction. Vitamin A_1 was estimated with the 3-point geometrical correction of Morton (see Absts. 4695, Vol. 21; 2824, Vol. 23). Values for vitamin A_2 were calculated from the observed spectrographic data at 693 mμ. in the product of the $SbCl_3$ reaction. Vitamin A values in I.U. per g., were for Waghbeer (*Galeocerdo tigrinus*) 2751, Win (*Pristis microdon*) 6242, Kanat (*Sphyrna blochii*) 8821, Khada (*Carcharinus malenopterus*) 12,147, Pisori (*Carcharinus limbatus*) 23,415, and Boot (*Sphyrna zygaena*) [not *Sphyrnazy gaena* as in Table 1] 82,667. Values for vitamin A_2 ranged from 250 I.U. per g. for a species of Kanat to 6500 for one of Boot, and the percentage of *neo*vitamin A from 19·9 for Win to 32·5 for Boot; iodine values ranged from 74·5 for Waghbeer to 139·0 for Kanat. The free fatty acid content of all the oils examined varied between 0·1 and 0·2 per cent.—I. M. Sharman.

2955

SCHARRER, K. and RÄKER, K. O. Der Carotingehalt von Futter- und Gemüsepflanzen sowie von natürlich und künstlich getrocknetem Pflanzenmaterial. **[Carotene content of fodder plants and vegetables and of naturally and artificially dried plant material.]** *Ztschr. Tierernährung Futtermittelk.*, 1956, **11**, 37–44. [Agrikulturchem. Inst., Justus-Liebig Hochsch., Univ. Giessen.] English summary.

Moisture and α- and β-carotene were estimated in 12 fresh fodder plants, 13 fresh vegetables, 4 types of silage, 5 types of hay, and several types of artificially dried forage. Certain of the dried materials were analysed also after 6 months' storage. The carotene values were highest in *Daucus carota*, *Medicago sativa*, *Brassica oleracea bullata*, *Helianthus annuus* and *Spinacea oleracea*, α-Carotene was present in all materials, and made up, on the average, about 4·5 per cent. of the total carotene. Carotene loss was high during haymaking and low in artificial drying.—V. H. Booth.

2956

SHMANENKOV, N. A. and GALICHNIKOVA, L. A. Znachenie dlya zhivotnykh i metodika opredeleniya vitamina A i karotina v kormakh. **[Significance for animals of, and method of estimating, vitamin A and carotene in the feed.]** *Veterinariya*, 1955, **32**, No. 9, 75–78. [Vses. Nauch.-Issled. Inst. Konevodstva.]

The loss of carotene from hay stacked for 9 months amounted to from 50 to 90 per cent.; fodder should be ensiled to reduce the loss. The average content in mg. per kg. of different types of fodder is shown and carotene requirements of domestic animals, pregnant and non-pregnant, are given.

To control the vitamin A intake of livestock it is recommended that carotene in fodder, especially hay, should be estimated by the method of Nasterovoi (Minist. Sovkhoz., 1951), by which a

representative sample of from 100 to 200 g. is finely divided, and 3 g. are powdered with sand or ground glass. The powdered hay is placed in a funnel blocked with cottonwool and covered with a 2-cm. layer of adsorbent such as aluminium oxide or calcium oxide. Carotene and chlorophyll are extracted with benzene, the carotene in solution passing through the adsorbent. The total amount of benzene used should be 60 ml. The carotene solution is matched against standard 10-ml. tubes, containing a mixture of alcohol with 1·01, 2·13, 3·19 or 4·25 ml. nitrobenzene. The respective colours are equivalent to carotene contents of 10, 20, 30 and 40 mg. per kg. hay. The standard tubes should be closed with rubber corks and kept in a dark room.—F. Billewicz.

2957

BOOTH, V. H. **The loss of carotene from dried green crop during storage. The gradient of loss through a stack.** *J. Sci. Food Agric.*, 1956, **7**, 114–119. [Dunn Nutrit. Lab., Milton Rd., Cambridge.]

Carotene was estimated in samples from 14 sacks from the middle, and 14 from the outside corners, of a stack of 10 tons of lucerne meal which contained 400 sacks. From the sacks in the centre 55 per cent. of carotene was lost against only 40·6 per cent. from the corner sacks. In a second experiment lucerne meal with a moisture content of 5 per cent. and a carotene content of 270 p.p.m. was put into 13 paper sacks and 9 polythene bags, which were sealed. Extra water was sprayed on to another portion to bring the water content to 10 per cent. and the moistened meal was filled into 2 paper sacks and 9 polythene bags. The 15 paper sacks and 18 polythene bags were distributed in the 2 middle courses of a large stack on a definite plan. The average difference in temperature between the inside and outside of the stack was 6·8° C. Moistened meal from the centre and outside, respectively, of the stack lost 13·2 and 7·5 per cent. of carotene; the corresponding dry meal lost 37·6 and 26·0 per cent. The differences between centre and outside for the same kind of sample gave a rough estimate of the effect of the difference of 6·8° C. in temperature. The protective effect of moisture was more important. In order to study further the effect of moisture, meal of 3 per cent. moisture content was filled into a tube 2·5 metres by 4 cm., closed at one end. After 28 weeks the tube was cut and moisture and carotene were estimated in the sections. In the first 8 cm. the moisture content had risen to an average of 10·5 per cent. and the carotene loss was 37·4 per cent. In the next 16 cm. the average moisture content was 4·9 per cent. and the carotene loss 42·8 per cent. The meal in the rest of the tube still had a moisture content of 3 per cent. and the average carotene loss was 54·2 per cent.

VITAMIN D

2958

RAOUL, Y., LE BOULCH, N., GUERILLOT-VINET, A., DULOU, R. and BARON, C. Structure stéroïde à noyau B ouvert et oxygéné du produit antirachitique obtenu par action d'une argile activée sur le cholestérol. [**Steroid structure, with B ring open and oxidised, of the antirachitic product obtained by the action of an activated clay on cholesterol.**] *C.R. Acad. Sci.*, 1955, **241**, 1882–1884.

A structural formula based on its chemical reactions is proposed for an antirachitic substance previously described (Absts. 346, 2948, Vol. 24; 1875, 3436, Vol. 25). The substance differs from other antirachitic substances in being an $\alpha\beta$-ethylenic ketone linked to a tertiary alcohol. It is biologically very active and is present in certain natural products.—E. M. Hume.

2959

LOUW, D. F., STRATING, J. and BACKER, H. J. **Δ^5-Steroids and provitamins D with branched side-chains. 4. The conversion of some Δ^5-steroids into provitamins D.** *Rec. Trav. chim. Pays-Bas*, 1955, **74**, 1540–1554. [Lab. Org. Chem., Univ. Groningen.]

The conversion of some new Δ^5-steroids into provitamins D is described. A provitamin D was prepared with a side-chain ending in a tertiary amine function. Four new provitamins D were prepared and samples of at least 90 per cent. purity were tested for antirachitic activity after irradiation with ultraviolet light. The purified esters were used for spectrophotometric investigation. The antirachitic activity was lessened when a methylene group was introduced into the aliphatic side-chain, and introduction of a second methylene group lessened it still further. There was an increase of antirachitic activity when a dimethylamide group was reduced to the physiologically active dimethylamine group.

YODER, L. and THOMAS, B. H. **Sulfonation and inactivation of vitamin D_2 by aqueous sulfite and aeration.** *Arch. Biochem. Biophys.*, 1956,

60, 392–397. [Chem. Labs., Iowa Agric. Exp. Stat., Ames.]

Small amounts of atmospheric oxygen were admitted to a flask filled with hydrogen, in which was a solution of crystalline vitamin D_2 in a mixture of pyridine and water, containing SO_2 with or without maize oil. The air was stirred continuously into the flask for $13\frac{1}{2}$ hr. The degree of sulphonation was measured. Samples were withdrawn after $1\frac{1}{2}$ and 6 hr. Presence of maize oil did not prevent sulphonation. Tested biologically, the sulphonated vitamin was without antirachitic potency.—E. M. Hume.

CARLSSON, A. and LINDQUIST, B. **Comparison of intestinal and skeletal effects of vitamin D in relation to dosage.** *Acta physiol. scand.*, 1955, **35,** 53–55. [Dept. Pharmacol., Univ. Lund.]

Rats 25 days old were fed on a modification of Steenbock and Black's diet with a Ca content of only 0·04 per cent. After 21 days a single dose of 10 or 100 or 1000 I.U. vitamin D_2 was given orally, or none. Four days later 20 mg. Ca as the lactate, containing ^{45}Ca, was given, and after 18 hr. the rats were killed. The increase in absorption of ^{45}Ca caused by giving vitamin D was no greater with 100 or 1000 I.U. than with 10. The serum Ca value was progressively greater, the greater the dose of vitamin D. In the given conditions the serum Ca value is held to reflect the extent of bone resorption, which with large (pharmacological) doses of vitamin D is much greater than, but not in quality different from, that with small (physiological) doses. The process of bone accretion, representing the antirachitic effect of vitamin D, is present in both cases, but with large doses bone resorption far exceeds what is necessary for bone accretion, so that the blood and soft tissues become overloaded with bone minerals. Meanwhile intestinal absorption of Ca proceeds regardless of the large size of the dose of vitamin D, and the effect of absorption is far outweighed by the effect of resorption.—E. M. Hume.

2962

CARLSSON, A. and LINDQUIST, B. **A comparative study on the mode of action of dihydrotachysterol and vitamin D on the calcium metabolism.** *Acta paediat.*, 1955, **44,** 548–558. [Dept. Pharmacol., Univ. Lund.] French, German and Spanish summaries.

Small groups of rats 25 days old were given a diet containing, per cent., Ca 1·48 and P 0·25, or Ca 0·04 and P 0·48. After 21 days they were given vitamin D_2 or dihydrotachysterol; from 6 hr. to 6 days, but usually 4 days, later labelled Ca, 20 mg., as the lactate was given by mouth and the rats were killed 18 hr. afterwards. Radioactivity was estimated in certain tissues and Ca was estimated in the serum.

In the first experiment the rats received the high-Ca diet and were given 300 μg. dihydrotachysterol. Six rats received the labelled Ca immediately and 2 after 6, 12 and 24 hr., and 2, 4 and 6 days. Radio-activity in the femur increased progressively, the effect being fully developed after a few days. The effect was like that of vitamin D.

In the second experiment, groups of from 2 to 4 rats were given the diet high or low in Ca with dihydrotachysterol in doses, in μg., of 0·03, 0·3, 3, 30, 300 or 3000 or none. All those having 3000 μg. died. With doses above 3 μg. there was only a small increase in the rate of uptake of radioactivity in the femur, and the behaviour with doses of from 3 to 30 μg. corresponded with that with a dose of 10 I.U. vitamin D.

In the third experiment, groups of from 4 to 10 rats were given the low-Ca diet with doses of 30, 300 or 3000 μg. dihydrotachysterol or of 10, 100 or 1000 I.U. vitamin D or none. Again all the rats given 3000 μg. dihydrotachysterol died or were very sick. The effect of 10 I.U. vitamin D and of 30 μg. dihydrotachysterol was about the same on the serum Ca value, the percentage of radioactivity absorbed, and the ratio-activity in the femur and tibia as percentage of the dose.

In the fourth experiment intact rats fed on the low-Ca diet and parathyroidectomised rats fed on the high-Ca diet were given 30 μg. dihydrotachysterol or 100 I.U. vitamin D or no dose. There was no difference in the effect of the two substances in presence or absence of the parathyroid glands.

It is, therefore, concluded that the effects of the two substances are the same but that vitamin D_2 is more active and the therapeutic range of dihydrotachysterol is smaller, toxic effects being relatively more easily produced.—E. M. Hume.

PILEGGI, V. J., DE LUCA, H. F., CRAMER, J. W. and STEENBOCK, H. **Citrate in the prevention of rickets in rats.**

CRAMER, J. W., PORRATA-DORIA, E. I. and STEENBOCK, H. **A rachitogenic and growth-promoting effect of citrate.** *Arch. Biochem. Biophys.*, 1956, **60,** 52–57; 58–63. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

(*a*) Young male rats weighing about 70 g. were given for 21 days a non-cereal basal diet low in Ca and P. Ca was added as $CaCO_3$ to make the Ca content 0·5 per cent., P as an equimolar mixture of KH_2PO_4 and K_2HPO_4, phytate P as Ca phytate,

and citric acid as a mixture of 0·02 mole citric acid with 0·02 mole Na citrate per 100 g. diet. When vitamin D was given it was as 75 I.U. vitamin D_2 every 3 days.

Addition to the basal diet of vitamin D or citrate or both promoted weight gain, increased bone ash and plasma inorganic P and decreased the width of the uncalcified layer of cartilage between the epiphysis and diaphysis. Citrate was more effective than vitamin D alone; both together were more effective than either alone. Citrate increased the proportion of dietary phytate hydrolysed much more than vitamin D did, and addition of vitamin D to citrate increased it only slightly. Unlike vitamin D, citrate decreased the activity of faecal and intestinal phytase and alkaline phosphatase. It is concluded that the effect of citrate lay in its Ca-complexing effect. With phytate-free diets, citrate had no antirachitic effect when the percentage of P was 0·015 and of Ca was 0·5, or when the percentage of P was 1·2 and of Ca 0·02, but when the percentage of P was 0·2 and of Ca 1·0, citrate had about the same degree of antirachitic effect as vitamin D.

(*b*) To the same non-cereal diet with 0·02 per cent. P, $CaCO_3$ was added to make the Ca content 0·5 per cent. Vitamin D was given and citrate incorporated in the diet as just described. Food intake of some rats was restricted to 20 g. to last 3 days, and others had food to appetite. The rats weighed from 76 to 80 g. Urine and faeces were collected every 3 days for 9 days from groups of from 5 to 7 rats. Calculi occurred when citrate was given; Ca content was added to that of the urine.

When citrate was given the faecal excretion of Ca was greatly increased; the effect was relatively less when the absorption of Ca was greater under the influence of vitamin D. The Ca balance was negative whether vitamin D was given or not, but it was less so when vitamin D was given. The P balance was negative and citrate had no effect on it unless vitamin D was given, when citrate increased the loss of P. It is concluded that in the circumstances described citrate had a rachitogenic effect.

The effect of citrate in reducing the power of vitamin D to depress the growth of rats given a diet adequate in Ca and low in P is attributed to its action in promoting withdrawal of Ca and P from the skeleton and thereby making more P available for growth.—E. M. Hume.

2964

LARON, Z., CANLAS, B. D. (Jr.) and CRAWFORD, J. D. **The action of cortisone on the teeth of rachitic rats.** *Arch. Pathol.*, 1956, **61**, 177–180. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Thirty rats weighing from 45 to 50 g. were given a rachitogenic diet low in Ca without vitamin D. After 17 days groups were given daily for 3 days 100 " units " vitamin D, or 80 mg. Ca as Ca lactate, or 2 or 5 mg. cortisone acetate, or combinations of 2 or 3 of the supplements, or no addition. At the end of 3 days blood was taken for analysis and the rats were killed. A portion of the upper maxilla with the two median incisors was taken for histological examination.

The value for serum inorganic P did not vary and the mean for all groups was 13·6 mg. per 100 ml. Serum alkaline phosphatase was lower when cortisone was given. The mean for all rats not given cortisone was 84 Bodansky units per 100 ml., and for rats given cortisone it was 73; the difference was barely significant. Serum Ca values were little increased by vitamin D or Ca, being between 4 and 5 mg. per 100 ml. whether either of them was given or not, but when both were given the mean value was 8·8. The mean values were always higher with cortisone, being with vitamin D 6·0, with Ca 6·8 and with both 9·2. In the incisor teeth, rats having the rachitogenic diet alone showed marked widening of the predentine, and other irregularities. When vitamin D or Ca was given, the predentine was narrower, and cortisone added to either of them had no further effect. When both were given, the predentine was reduced to a thin layer, which was not so thin when cortisone was given as well.

2965

STEENBOCK, H. and HERTING, D. C. **Vitamin D and growth.** *J. Nutrition*, 1955, **57**, 449–468. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats weighing from 70 to 80 g., usually male, were given a basal diet of, per cent., glucose 67, steamed egg white 18, cottonseed oil 10, roughage 3, salt mixture without Ca or P 2, and a mixture of water-soluble vitamins. Vitamins A, E and K were given in oil 3 times a week. Ca was added as $CaCO_3$ and P as a neutral equimolar mixture of KH_2PO_4 and K_2HPO_4. When very large amounts of Ca were required P was added as $Ca_3(PO_4)_2$. Before the experiment 9 representative normally fed rats of mean weight 73 g. were analysed to obtain mean values for serum Ca and inorganic P and for certain characteristics of the femur. When vitamin D was given it was as 75 I.U. vitamin D_2 on the first and every third day. The experiments usually lasted 21 days.

With a diet containing only 0·018 per cent. Ca and P ranging from 0·016 to 1·168 per cent. the rats lived for many weeks, but growth was more strongly inhibited the greater the content of P. Addition of vitamin D overcame the inhibition and

growth continued for a further 7 weeks at all levels of P intake. Without vitamin D half the rats died within 9 weeks; the value for serum P was excessively high and for serum Ca excessively low; vitamin D corrected both.

With a diet containing 0·3 per cent. P and from 0·21 to 2·63 per cent. Ca, the addition of Ca increased growth to some extent but not as much as addition of vitamin D. With vitamin D addition of Ca had only a small effect, and the largest amounts of Ca inhibited growth. Addition of Ca was less beneficial to bone than addition of vitamin D. The width of metaphyseal cartilage was normal except in rats given much Ca and no vitamin D, in which there was a rachitic widening. Whether the salt supplying Ca was highly basic or not made no difference.

With a diet containing adequate Ca, 0·45 per cent., and increasing amounts of P, the effect of vitamin D was not as great as when the Ca content was low. The difference seemed to be due to the higher value for serum Ca maintained by the higher intake.

Further experiments were made in which rats were started on diets with and without vitamin D. When the weight of those with vitamin D exceeded that of those without by about 10 g., the amount of Ca or P or both was raised or lowered. No change was as effective in increasing growth as administration of vitamin D. Consumption on alternate days of the diet containing either added Ca or added P again failed to give a growth performance as good as that with vitamin D.

From the fact that, with diets low in Ca and high in P, addition of Ca was less effective in promoting growth than addition of vitamin D, it was concluded that the action of vitamin D is not limited to the absorption and deposition of bone salts, but that the vitamin has a more widespread effect on organic tissue metabolism, of which increased growth is one manifestation.

E. M. Hume.

2966

Herting, D. C. and Steenbock, H. **Vitamin D and gastric secretion.** *J. Nutrition*, 1955, **57**, 469–482. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats weighing from 70 to 95 g. were given a stock diet or a rachitogenic diet low in P with maize and wheat gluten, or a semi-synthetic rachitogenic diet (see preceding Abst.) to which NH_4Cl, $NaHCO_3$ and Ca and P and vitamin D were added as described above. The experiments lasted 21 days. After from 16 to 24 hours' starvation, or less if there was a risk of tetany from low-Ca diets, the pyloric sphincter was tied and gastric secretion was collected 6 hr. later, no water having been given.

The addition of vitamin D increased the volume of gastric secretion and reduced the *p*H, but the values were never beyond those obtained with a stock diet. The effect of vitamin D was to restore the normal state. The difference in *p*H with and without vitamin D was greatest with diets low in P or in available P. With diets high in P or normal diets there was no effect. The Ca content of the diet had no influence except on the availability of P. The changes in the volume of secretion usually reflected those in *p*H, being increased by vitamin D, but not invariably, so that the mechanisms governing the two functions might not be the same. The effect of vitamin D was not modified by altering the acid base balance in the diet or by injecting histamine. Serum P increased when vitamin D exercised its effect on gastric *p*H, but it might increase without that effect being present.

No obvious correlation was found between water content of the body, volume of urine and gastric secretion. Ulcers in the stomach tended to be produced with diets high in Ca, and the tendency was greater when vitamin D was added.

Navazio, F. Cromatografia su carta dell'alfa-tocoferolo-fostato (alfa-tph). [**Paper chromatography of α-tocopheryl phosphate.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 550–551. [Ist. Chim. Biol., Univ. Rome.]

The mixture of solvents used was pyridine, *iso*butanol, distilled water and concentrated acetic acid, in the proportions 20 : 30 : 50 : 5, at *p*H 6. The spots were developed by spraying the paper with 1 per cent. $FeCl_3 . 6H_2O$ in 80 per cent. alcohol. The spot for α-tocopheryl phosphate was light yellow on a dark orange ground. The method distinguished it from adenosine triphosphate, cocarboxylase and glucose-1- and glucose-6-phosphate. The amount of α-tocopheryl phosphate in the spot could be estimated by measuring the amount of P.—E. M. Hume.

Green, J. and Marcinkiewicz, S. **η-Tocopherol (7-methyltocol): a new tocopherol in rice.** *Nature*, 1956, **177**, 86–87. [Walton Oaks Exp. Stat., Res. Labs., Vitamins, Ltd., Dorking Rd., Tadworth, Surrey.]

The lipoid fraction of whole Japanese rice was

saponified with alkali and the vitamin E complex was purified by treatment with Floridin earth. Two-dimensional chromatography as previously described by the authors (Abst. 4814, Vol. 25) showed that at least 3 tocopherols were present which moved to the positions of α-, ζ- and ε-tocopherol; γ- and δ-tocopherols were absent. The spot in the ε-position gave a strong positive reaction with diazotised *O*-dianisidine which is given only by tocopherols with the 5-position free. By methods not described ε-tocopherol was proved to be absent. The new spot was considered to be 7-monomethyltocol and was named η-tocopherol. Rice contained α-, ζ- and η-tocopherols in the proportion 47 : 26 : 27. η-Tocopherol had an absorption maximum at 293 mμ.; $E\ ^{1\ per\ cent.}_{1\ cm.} = 78$. It gave a yellow nitroso derivative with nitrous acid, and on oxidation with nitric acid gave a red *O*-quinone with absorption maximum at 477 mμ., and $E\ ^{1\ per\ cent.}_{1\ cm.} = 56$.—R. J. Ward.

NAVAZIO, F. and FIORETTI, P. Effetto dell'alfa-tocoferolo-fosfato sul tasso plasmatico dei caroteni. [**Effect of α-tocopheryl phosphate on the plasma value for carotenes.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 552–554. [Ist. Chim. Biol., Univ. Rome.]

Vitamin A and carotene were estimated by the Carr Price method in the blood plasma of normally fed male dogs weighing about 12 kg. before and 8 hr. after administration by mouth or by intramuscular injection of 100, 150 or 200 mg. α-tocopheryl phosphate. In 9 experiments the vitamin A value was not changed but the carotene value was always increased. When an ethereal extract of the plasma was treated with methanol and passed through a column of $Ca(OH)_2$ to free it from xanthophylls, the amount of the residual α-, β- and *neo*-β-carotenes still remained greater after administration of tocopheryl phosphate than before it.—E. M. Hume.

CHRISTENSEN, F., DAM, H., GORTNER, R. A. (Jr.) and SØNDERGAARD, E. **"In vitro" hemolysis of erythrocytes from vitamin E deficient rats and chicks.** *Acta physiol. scand.*, 1956, **35,** 215–224. [Dept. Biochem. Nutrit., Polytec. Inst., Copenhagen.]

White female rats were given a basal diet without fat or tocopherol for 62 days followed by the same diet or one containing 2 or 20 per cent. lard. Some of the animals were given 0·02 per cent. α-tocopheryl acetate or 0·126 per cent. methylene blue. Tests for haemolysis were made on the erythrocytes by a slight modification of the method of György and Rose with dialuric acid. Of 72 rats given the fat-free diet for 62 days, 45 showed complete haemolysis in 4 hr. Vitamin E gave complete and methylene blue partial protection. The inclusion of lard in the diet did not affect haemolysis. When physiological saline was substituted for the dialuric acid and buffer solutions in the test, haemolysis occurred in the erythrocytes from deficient rats, the preparations being kept at 37° C. for 2 or 4 hr. Haemolysis was complete in 1 hr. when the temperature was 47° C. Dietary methylene blue gave partial, and dietary vitamin E complete, protection against the occurrence of such haemolysis. Spontaneous haemolysis did not occur when purified nitrogen was bubbled through the suspension of erythrocytes.

The erythrocytes of deficient chicks were more resistant to haemolysis than those of rats and only faint haemolysis occurred within 4 hr., even when dialuric acid was added.—R. J. Ward.

2974

MORGULIS, S., KAREL, J. L. and WILDER, V. M. Dystrophie musculaire nutritionnelle et "le quotient de créatine". [**Nutritional muscular**

dystrophy and the creatine quotient.] *Bull. Soc. Chim. biol.*, 1955, **37**, 851–856. [Dept. Biochem., Coll. Med., Univ. Nebraska, Omaha.]

Young rabbits weighing from 400 to 500 g. were fed as described earlier (Abst. 2903, Vol. 11), with or without α-tocopherol. The tocopherol-free diet produced dystrophy. In both groups the creatine quotient, QC,

$$\frac{\text{total creatinine} - \text{pre-formed creatinine}}{\text{total creatinine}} \times 100$$

in urine was estimated.

In 32 urine samples from normal rabbits the value of the QC was from 9·7 to 23·7, mean 15·4 ± 3·7, and individual variations during 2 or 3 weeks were slight. In the deprived rabbits the value began to rise before signs of dystrophy appeared; it continued to rise and the animals usually died with clinically severe dystrophy when it exceeded 80. Individual variations from day to day were very large. In rabbits with advanced dystrophy and QC between 70 and 80, treatment with α-tocopherol was followed by very rapid fall of the QC to normal in from 2 to 4 days. Recovery of normal muscular structure and function followed more slowly.—D. Duncan.

2975

DINNING, J. S. **The influence of vitamin E deficiency on the incorporation of various radioactive precursors into urinary creatinine by the rabbit.** *Arch. Biochem. Biophys.*, 1956, **60**, 501–502. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

White male New Zealand rabbits were given a diet without vitamin E, with or without supplements of 10 mg. α-tocopheryl acetate twice a week. When the deprived animals showed signs of muscular dystrophy, both groups were given intraperitoneal injections of 10 μC. per 100 g. bodyweight of sodium formate-^{14}C, glycine-1-^{14}C or glycine-2-^{14}C. The animals were killed 4 hr. after injection and the specific activity of urinary creatinine was estimated. When sodium formate was injected the specific activity for the normal animals was 56 counts per min. per μ*M* and for the deficient animals 855. With glycine-1-^{14}C the corresponding values were 46 and 664, and with glycine-2-^{14}C 59 and 266.—R. J. Ward.

2976

RUMERY, R. E., MAUER, S. I. and MASON, K. E. **Muscle protein fractions in late-lactation paralysis of vitamin E deficient rats.** *J. Exp. Zool.*, 1955, **129**, 495–503. [Dept. Anat., Sch. Med. Dent., Univ. Rochester, N.Y.]

Gastrocnemius muscle was taken from rats at ages from 5 to 30 days for estimation of insoluble protein, actomysin and soluble protein. Some of the young rats had been reared by mothers which had received a stock diet, but the mothers of others had been transferred to a diet deficient in vitamin E immediately before mating. Young from the mothers deprived of vitamin E became paretic between the ages of 18 and 25 days, and in that period there was a rapid fall of actomysin and a sharp rise in the insoluble protein in muscle. Spontaneous recovery, which occurred before the 30th day in those animals which did not die, was accompanied by a compensatory rise of actomysin. In the animals on stock diet actomysin increased steadily and insoluble protein decreased throughout the period between the 18th and 30th days.

TARJÁN, R. and KRAMER, M. (with SZÁNTÓ, M. and TÓTH, A.). Veränderungen im Vitamin-E-Gehalt der Organe und Gewebe junger Ratten bei Verabreichung von Diäten mit verschiedenem Vitamin-E-Gehalt. [**Changes in the vitamin E content of organs and tissues in young rats given diets with different contents of vitamin E.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 220–225. [Inst. Ernährungswiss., Budapest.] English and French summaries.

Young rats were given for 10 weeks a diet deficient in vitamin E with 0·9, 4·6 or 9·5 mg. vitamin E per 100 g. diet, after which they were killed and the vitamin E content of some organs was estimated. The vitamin E content of the liver did not significantly increase with increasing intake; the values were 6·6, 7·0 and 7·3 mg. per 100 g. Vitamin E in the serum rose from about 0·1 mg. per 100 ml. with the lowest intake to 0·4, and to 0·9 with the highest. The greatest increase was in the adrenal glands with values of 3·4, 6·3 and 22·5 mg. per 100 g. for the respective intakes.

CHERNICK, S. S., MOE, J. G., RODNAN, G. P. and SCHWARZ, K. **A metabolic lesion in dietary necrotic liver degeneration.**

ROSECAN, M., RODNAN, G. P., CHERNICK, S. S. and SCHWARZ, K. **Acetate-2-C^{14} utilization in dietary necrotic liver degeneration.** *J. Biol. Chem.*, 1955, **217**, 829–843; 967–976. [Nat. Inst. Arthritis Metabol. Dis., Nat. Insts. Health, Bethesda, Md.]

(*a*) Rats 18 to 20 days old were given a basal diet containing, per cent., torula yeast 30, sucrose 59, vitamin-E-free lard 5, salts 5 and vitamin mixture in lactose 1. Mean survival of rats on this diet is 45 days and all develop liver necrosis. After 18 to 22 days some of the rats received supplements of vitamin E, 0·5 or 1 per cent. L-cystine, 1 per cent. L-cysteine, 1·23 per cent. DL-methionine or a source of factor 3 (Abst. 1037,

Vol. 22); the rest continued on the basal diet. After from 21 to 200 days from weaning rats were killed; oxygen consumption was studied with slices of liver and other tissues and liver homogenates.

Liver slices showing gross necrosis consumed oxygen very slowly. Histologically normal slices from rats on the basal diet showed normal oxygen consumption for 30 min. and then a rapid decline. This was prevented by the supplement of vitamin E and did not occur in slices from rats on stock diet. Slices of kidney or diaphragm from rats on the basal diet had normal oxygen consumption, even when the liver showed gross necrotic change. The value of amino acids and factor 3 preparations in preventing respiratory decline was proportional to their value in preventing necrosis.

Liver homogenates from rats on the basal diet, with additions of $MgSO_4$, cytochrome *c*, adenosine triphosphate, diphosphopyridine nucleotide, nicotinamide, fructose diphosphate and pyruvate in different combinations, showed no metabolic difference from normal liver homogenates.

Liver damage produced by a high-fat, low-protein diet, 5 per cent. cystine or 0·5 per cent. ethionine did not reproduce the same metabolic defect.

(*b*) Liver tissue from rats fed as described above and free from evidence of disease was incubated in Warburg vessels at *p*H 7·4 and 37·2° C. in Krebs's phosphate buffer with sodium acetate-2-^{14}C. Recoveries of ^{14}C were measured in acetoacetic acid, lipids and CO_2 for up to 2 hr. Metabolism of acetate was found to decline rapidly in tissue from rats on the basal diet, but continued for the whole experiment in tissue from rats fed on stock diet or given vitamin E.

In rats on basal diet the fasting blood ketone value was lower than that of rats given vitamin E.

Metabolic activity in liver slices was restored 1 hr. after intraperitoneal injection of vitamin E emulsion into fasting rats previously fed on the basal diet.—D. Duncan.

2979

PROSPERI, P. and BORSELLI, L. Studio istologico sulla ipervitaminosi E nella cavia. [**Histological study of vitamin E excess in the guinea-pig.**] *Riv. Clin. pediat.*, 1955, **56,** 378–391. [Ist. Clin. Pediat., Univ. Florence.] English and French summaries.

Of 18 guineapigs [total number stated to be 30 but no account given of 12], weighing from 250 to 300 g., all having the same [presumably complete] diet, 6 were given 100 mg. vitamin E daily for 10 days, 6 had 300 mg. daily for 10 days, 2 had a single dose of 600 mg., 2 of 900 mg. and 2 of 1200 mg. The last 6 were all killed 4 days later. The vitamin was given by intramuscular injection. All the animals appeared perfectly well except those given 1200 mg., which seemed dull with a staring coat. Those in the two first groups gained weight; the weight of the other 6 remained unchanged. Histological examination of tissues and organs showed no change in the group given 100 mg. In the other groups there were changes, of severity increasing gradually with increasing dose, though only very marked with the largest dose. There were degenerative changes in the liver, and oedema in the myocardium and brain. In the endocrine glands there were signs of overstimulation in the pancreas, pituitary gland, testes and ovaries.

The results suggested that on a bodyweight basis there was no reason for apprehension about the size of the doses of vitamin E commonly given to human beings.—E. M. Hume.

2980

TAYLOR, D. W. **The effects of vitamin E and of methylene blue on the manifestations of oxygen poisoning in the rat.** *J. Physiol.*, 1956, **131,** 200–206. [Dept. Physiol., Univ. Aberdeen.]

Weanling hooded rats given a diet with supplements of other vitamins but without vitamin E were divided into 4 groups each of 4 males and 4 females. Group E received a supplement of 5 mg. α-tocopheryl acetate twice weekly; group M received 0·15 per cent. methylene blue in the diet, and group ME received both. Group O had no supplement. When aged from 180 to 200 days all the animals were exposed to oxygen at a pressure raised from 1 to 5 atmospheres at the rate of 10 lb. per sq. in. per min. Signs of oxygen poisoning appeared successively as twitching and jerking of the ears, head and limbs, then violent shivering and convulsions which were quickly followed by prostration and death. The time from the initial rise of oxygen pressure to the appearance of convulsions and prostration was measured in each group. Blood samples for the dialuric acid haemolysis test were taken immediately after decompression.

Methylene blue prevented pigmentation of the uterus and loss of weight by the testes. The total testicular tissue for group O was on the average 1·21 g. per rat, and for groups E, M and ME it was 2·76, 2·45 and 2·54 g. The mean time to onset of oxygen poisoning was 33 min. in group O, 36 in group ME, 44 in group M and 56 in group E. Tocopherol and methylene blue given separately provided a significant ($P < 0·01$) degree of protection but given together did not alter appreciably the time to onset of poisoning. The difference between groups M and E suggests a failure of methylene blue to replace vitamin E fully. When blood from the test rats without vitamin E was centrifuged for the haemolysis test the supernatant liquid was already so deeply coloured by

haemolysis, whether the animals received methylene blue or not, that it was impossible to make the test.—I. M. Sharman.

2981

SACCO, T. Sull' azione masteoplastica della vitamina E. [**Effect of vitamin E on the mammary glands.**] *Riv. Zootec.*, 1955, **28,** 347–349. [Ist. Fisiol. Animali Domest., Bologna.]

See Absts. 1534, 4108, Vol. 23, in which it was shown by Piana that vitamin E promoted mammary development in female guineapigs.

Three groups of 10 male guineapigs received a mixed diet with fresh green food and 15 mg. ascorbic acid daily. One group consisted of 5 entire males and 5 castrates. In the second group of 10 entire males, and the third of 10 castrates, each animal received daily by mouth 20 mg. α-tocopherol in oil; treatment began 3 weeks after castration and continued for just over 3 months.

The guineapigs given α-tocopherol developed slightly greasy coats. When they were killed their mammary glands were slightly larger than those of the group not given tocopherol, but there was no histological difference except for the presence of more fat and a greater development of sebaceous glands. It is considered possible that the oil in which the α-tocopherol was dissolved was responsible for the difference.

It is concluded that the effect of α-tocopherol is not comparable with that of folliculin, at least for the male guineapig.—D. Duncan.

2982

LUDOVICY, R. Influence de l'α-tocophérol sur la sensibilisation au potassium. [**The effect of α-tocopherol on potassium sensitivity.**] *Arch. internat. Pharmacodyn.*, 1955–56, **104,** 196–203. [Lab. Physiol., Inst. Léon Frédéricq, Univ. Liège.]

The injection of *dl*-α-tocopheryl disodium phosphate into the lymphatic sacs of frogs from 5 to 24 hr. before dissection decreased by 50 per cent. the sensitivity to potassium, induced by sodium thiocyanate, of the isolated rectus abdominis muscle. Tocopherol also decreased by 40 per cent. the sensitivity to K induced by caffeine, but that induced by veratrin was not affected.—T. Moore.

2983

DARLINGTON, F. G. and CHASSELS, J. B. **A study on the breeding and racing of thoroughbred horses given large doses of alpha tocopherol. 1. Breeding experiments. 2. Racing experiment.** *The Summary*, 1956, **8,** 1–10; 10–20. [Nat. Stud Farm, Oshawa, Canada.]

1. The 34 brood mares studied included 17 barren and maiden mares and 4 most difficult to get in foal; 7 had an average age of 17 years. All were given from 600 to 1000 I.U. α-tocopheryl succinate daily from April 1955. Apart from the maiden mares, the proportion of the mares which had had foals in the 5 preceding years was 15 out of 17, 15 out of 24, 15 out of 24, 17 out of 26 and 17 out of 28; in 1956, 30 were in foal and only 4 barren. Of the 4 barren mares 1 had cystic ovaries, 2 gave haemolytic streptococci in cervical swabs and 1 had been barren 4 times in 6 years. Of 27 other mares not given α-tocopherol, 19 were in foal in 1956.

A decline in fertility of maiden mares is attributed to "the indiscriminate use of hormone products during their racing career". Of 6 such treated with tocopherol, all conceived.

The 5 stallions studied had an average age of 11 years and in the 5 years before experiment had a record of 178 foals from 270 mares; in 1955 they received α-tocopherol and 76 out of 86 mares served were found to be in foal. Two younger stallions also improved in performance. In an old gelding teaser given testosterone for 12 years the implanted testosterone had a more lasting effect when α-tocopherol was given.

2. A group of 15 racehorses received α-tocopherol in the 1955 season, usually 2000 I.U. daily. The horses appeared less nervous, ate better, and were more successful in racing performance than in the previous season.—D. Duncan.

2986

SWINGLE, K. F., SAFFORD, J. W. and MCROBERTS, D. E. **Tocopherol levels of the early milks of semirange cattle.** *Amer. J. Vet. Res.*, 1956, **17**, 28–35. [Montana Vet. Res. Lab., Bozeman.]

Samples of colostrum were taken on the first 4 days after parturition and of milk (7 samples in all) every 4 days, commencing at the eighth day, from 53 semi-range Hereford cows originating from 5 different herds, 3 of which, comprising 46 cows, had a previous history of white muscle disease, and from the cows of one dairy herd. The average tocopherol content in μg. per 100 ml. in the colostrum of individual beef cows ranged from 18 to 1357. The average for each herd ranged from 59 to 696. The average for the colostrum from the dairy herd was 283. Similarly, the average tocopherol values for the milk samples ranged from 16 to 501 μg. per 100 ml., with the averages for the herds ranging from 40 to 275. The average value for the milk from the dairy herd was 79. The lowest values were obtained from a herd which had previously suffered losses from white muscle disease, but the disease could not be definitely attributed to lack of tocopherol in the diet.

2987

KRUISHEER, C. I. **The total tocopherol (vitamin E) content of Dutch butter. (With reference to the carotene and vitamin A contents.)** *Nederlands Melk Zuiveltijdschr.*, 1955, **9**, 275–290. [Govt. Dairy Stat., Leyden.] Dutch summary.

Samples of butter from 18 creameries in different parts of the country were examined every month. Half of each sample was stored at — 20° C. for from 8 to 12 months (Abst. 1525, Vol. 26). Vitamin E was estimated by the $\alpha\alpha^1$-dipyridyl method after vitamin A and carotene had been removed by adsorption with Floridin XS. Vitamin A and carotene were estimated as previously described (Kruisheer and Den Herder, Absts. 275, 4151, Vol. 23). The butters were tested for flavour, particularly off-flavour of a fatty, fishy or fish-oil nature. The individual results are tabulated.

The mean tocopherol content in μg. per g. butter was for the whole year 20 with range 8 to 34, for the pasture period June to September 24 with range 20 to 34, and for the period in stall from December to April 15 with range 8 to 21. The corresponding values in μg. per 100 g. for whole milk as delivered to the factories were 88, 105 and 67, and for " drinking " milk standardised to 2·5 per cent. fat content the values were about two-thirds of those. For vitamin A and carotene the values were like those previously found (Absts. 275, 4151, Vol. 23).

Statistical examination of the results for the different months showed a significant correlation between carotene content and vitamin A content except in May and June. Between tocopherol content and carotene content there was no correlation from May to August, but for the other months there was a positive correlation with fair significance. Between tocopherol content and vitamin A content there was a positive correlation of varying significance. The findings gave some confirmation to the hypothesis that tocopherol promotes the assimilation and formation or stability of vitamin A and the stability of carotene. There was little or no correlation between tocopherol content and liability to develop off-flavour on storage, which seemed to be greater in the pasture period, and it was concluded that tocopherol in butter has no anti-oxidant activity of any importance. Tocopherol sometimes remained stable during storage and sometimes decreased, but the results were irregular and could not be correlated with such other variables as Cu content or intensity of oxidation defect.—E. M. Hume.

VITAMIN K

2988

SATHE, V., DAVE, J. B. and RAMAKRISHNAN, C. V. **Spectrophotometric method for the estimation of vitamin K_3.** *Nature*, 1956, **177**, 276. [Dept. Biochem., Fac. Sci., M.S. Univ. Baroda.]

When a solution of vitamin K_3 was shaken with ethanol, and 2 : 4-dinitrophenylhydrazine in 2*N* HCl and then Na_2CO_3 was added, a stable green colour developed, which could be removed through its solubility in amyl alcohol and used for spectrophotometric measurement of vitamin K_3. The method was suitable for micro-estimation of from 2 to 30 μg. vitamin K_3.—A. M. Copping.

2989

REBER, E. F., MORRILL, C. C., NORTON, H. W. and RHOADES, H. E. **Studies of the effects of chlortetracycline, vitamin E and vitamin K in the nutrition of the rat. 1. Growth.** *J. Nutrition*, 1956, **58**, 19–28. [Dept. Vet. Physiol., Coll. Vet. Med., Univ. Illinois, Urbana.]

Rats were given a basal diet without vitamins E and K, alone or with addition of vitamins E and K and aureomycin hydrochloride (chlortetracycline) in amounts of 0·02 or 0·03 per cent. singly or in their possible combinations. The experiment

was based on a factorial design. The addition of vitamin E or aureomycin increased growth significantly. Degeneration of the testes occurred in the rats fed on the basal diet alone, but not in those receiving any of the supplements. Vitamin E or aureomycin but not vitamin K increased the concentration of vitamin A in the liver from an average of 260 I.U. per g. to 1039 and 942 I.U. per g., respectively. In the colon, aureomycin reduced the number of coliform and lactic acid bacteria, and vitamin K reduced the number of coliform bacteria. Aureomycin or vitamin K increased the growth of yeasts in the colon.

MASONI, S., ZULIANI, F. and NEPPI LEVI, P. Potere antifungino e antibatterico delle associazioni vitamina K_5 (2-metil-4-amino-1-naftolo-cloridrato)-antibiotici. 1. Antagonismo e sinergismo nei riguardi dello *Staphylococcus pyogenes aureus*, del *B. coli*, del *B. pyocianeum* e della *Candida albicans*. [**Antifungal and antibacterial activity of associations of vitamin K_5 (2-methyl-4-amino-1-naphthol hydrochloride) and antibiotics. 1. Antagonism and synergism with regard to *Staphylococcus pyogenes*. *Bact. coli*, *B. pyocyaneum* and *Candida albicans*.**] 2. Antagonismo e sinergismo nei riguardi delle infezioni miste schizomiceti-fungo: *Staphylococcus pyogenes aureus*, *B. coli*, *B. pyocianeum* e *Candida albicans*. [**2. Antagonism and synergism with regard to mixed infections by schizomycetes and fungi: *Staphylococcus pyogenes aureus*, *Bact. coli*, *B. pyocyaneum* and *Candida albicans*.** *Arch. Sci. biol.*, *Bologna*, 1956, **40**, 38–46; 47–57. [Ist. Igiene, Univ. Modena.]

1. The antibacterial effect of penicillin, streptomycin, oxytetracycline, chlorotetracycline, chloramphenicol, subtilin and polymyxin, alone and combined with vitamin K_5, was investigated *in vitro* with several micro-organisms. The effect of the antibiotic substances on *Staphylococcus pyogenes aureus* was enhanced *in vitro* by vitamin K_5. With *Bact. coli* and *B. pyocyaneum* the effect of oxytetracycline and streptomycin was increased but there seemed to be antagonism between other antibiotics and vitamin K_5. Antagonism between vitamin K_5 and penicillin, oxytetracycline and polymyxin was shown with *Candida albicans*, but vitamin K_5 had no effect on the action of streptomycin and it increased the effect of other antibiotics.

2. Further studies were made with the same antibiotics and vitamin K_5 on mixed cultures of bacteria and the mould *Candida albicans*. The presence of vitamin K_5 did not appear to alter the effect of antibiotics on the mould in mixed cultures and the antibacterial effects were generally enhanced, with the exception of mixed cultures containing *B. pyocyaneum*, where greater doses of antibiotic were required to obtain a minimum effect.—A. M. Copping.

2991

ZULIANI, F. and MASONI, S. Su un eventuale potenziamento nell'attività antibatterica e antifungina dell'associazione di alcuni chemioterapici con la vitamina K_5 (2-metil-4-amino-1-naftolo-cloridrato). [**Potentiation of antibacterial and antifungal activity of some drugs by association with vitamin K_5 (2-methyl-4-amino-1-naphthol hydrochloride).**] *Arch. Sci. biol.*, *Bologna*, 1956, **40**, 58–65. [Ist. Igiene, Univ. Modena.]

The effect of combining vitamin K_5 with 8-hydroxyquinoline, *furazina* [? Furacin], chloramine, undecylenic acid or tyrothricin was investigated with *Staphylococcus pyogenes aureus*, *Bacterium coli* and *Candida albicans*, separately and in mixed cultures. The results suggested a synergic effect between vitamin and chemotherapeutic agent, especially in reactions against *Candida*. The possible use of vitamin K_5 as an aid to chemotherapy in clinical practice is suggested.

A. M. Copping.

GREEN, J. P., SØNDERGAARD, E. and DAM, H. **Intracellular distribution of vitamin K in beef liver.** *Biochim. biophys. Acta*, 1956, **19**, 182–183. [Dept. Biochem. Nutrit., Polytech. Inst., Copenhagen.]

Beef liver was homogenised and centrifuged to yield 3 fractions representing the nuclei, mitochondria and supernatant fluid. The fractions were tested biologically on chicks for vitamin K, and their activity appeared to be associated chiefly with the mitochondria.—A. M. Copping.

VITAMIN B COMPLEX: GENERAL

2993

LOY, H. W. (Jr.), PARRISH, W. P. and SCHIAFFINO, S. S. **The use of turbidity measurements in microbiological methods for vitamins.** *J. Assoc. Off. Agric. Chem.*, 1956, **39**, 172–179. [Food Drug Admin., Dept. Health, Educat. Welfare, Washington 25, D.C.]

The use of turbidity as criterion was investigated in microbiological methods for estimating folic acid, nicotinic acid, pantothenic acid, riboflavin

and vitamin B_{12}. With proper precautions measurement of turbidity gave results equal in validity to those of titrimetric methods. Certain changes are recommended in preparing the inoculum and concentrating the standard.—A. M. Copping.

2994

SCHIAFFINO, S. S., LOY, H. W. (Jr.), KLINE, O. L. and HARROW, L. S. **Application of the variable reference technique for the spectrophotometric determination of vitamins.** *J. Assoc. Off. Agric. Chem.*, 1956, **39**, 180–185. [Food Drug Admin., Dept. Health, Educat. Welfare, Washington 25, D.C.]

The use of a recording double-beam spectrophotometer for measuring concentrations of several components in a mixture containing vitamins of the B complex is reported. The method depended on the selection of suitable wavelengths characteristic of each component and on the absence of interfering substances. For concentrates in tablets and capsules and other pharmaceutical preparations the results showed accuracy similar to that obtained with other methods, and much time was saved.

A. M. Copping.

RERAT, A., LE BARS, H. and JACQUOT, R. Essai de localisation du lieu d'absorption des vitamines B dans le tube digestif du mouton. [**Attempt to locate the site of absorption of B vitamins in the digestive tract of the sheep.**] *C.R. Acad. Sci.*, 1956, **242**, 679–681.

The absorption of B vitamins was studied in 3 sheep by an indirect method in which chromic oxide as tracer was given with the diet of oats and lucerne hay, and the concentration of the insoluble tracer and of vitamins of the B complex was estimated in the rumen, reticulum, omasum, abomasum, small intestine, caecum, colon and rectum. From the results it seemed that absorption of the vitamins was at a maximum in the omasum and the small intestine. The observation was confirmed by direct measurement of vitamin B_1, riboflavin, nicotinic acid, pantothenic acid and vitamin B_{12} in venous blood obtained from the different sections of the gut and by comparison of the amounts with the amount of B vitamins in blood from the jugular vein.—A. M. Copping.

2997

BALAKRISHNAN, S., RAJAGOPALAN, R. and GIRI, K. V. **The present state of knowledge regarding biosynthesis of B-complex vitamins.** *Indian Med. Gaz.*, 1955, **90**, 7–19. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

MANNINO, N. and PIPITONE, V. Il problema della vitaminosintesi batterica nel quadro della resistenza agli antibiotici: ricerche con E. coli. [**Bacterial synthesis of vitamins and resistance to antibiotics. Researches on *E. coli*.**] *Bol. Ist. sieroterap. milan.*, 1955, **34**, 374–381. [Ist. Clin. Med., Univ. Bari.] English summary.

A strain of *Bacterium coli* was subcultured repeatedly in a synthetic medium without water-soluble vitamins, in presence of penicillin, aureomycin, terramycin, chloramphenicol or streptomycin. Growth was measured turbidimetrically. Vitamin B_{12}, folic acid, vitamin B_6 and nicotinamide were estimated microbiologically after 8 and 24 hr. in cultures of the strains rendered resistant to the different antibiotics and of the original, non-resistant strain, and in the medium itself. Synthesis of any of the vitamins was much less by strains resistant to any of the antibiotics.

E. M. Hume.

2999

MONDOLFO, H. and MONDOLFO HOUNIE, E. Sull'antagonismo esistente tra l'aureomicina e alcuni fattori metabolici (vitamine del gruppo B, guanina, adenina, ecc.). [**Antagonism between aureomycin and some metabolic factors (vitamins of the B complex, guanine, adenine, etc.)**] *Boll. Ist. sieroterap. milan.*, 1955, **34**, 536–540. [Buenos Aires.] English summary.

Strains of *Staphylococcus aureus*, *Bacterium coli* and *Lactobacillus arabinosus* were grown in a broth medium. The maximum concentration of vitamin B_1, riboflavin, pyridoxine, nicotinamide, Ca pantothenate, adenine, guanine, uracil and biotin which would not adversely affect the growth of the organisms was estimated. With that concentration of each of the substances singly, the growth of the organism was tested in the presence of graded concentrations of aureomycin. Nicotinamide and guanine had some power to counteract the effect of aureomycin for all 3 organisms, and for *Staph. aureus* Ca pantothenate and adenine also had some effect. Leucine and valine increased the toxicity of aureomycin. The other substances had little or no bacteriostatic effect.

With a synthetic medium also, nicotinamide and guanine partly counteracted the effect of aureomycin on *Bact. coli* and *Staph. aureus*. Combinations of substances were more effective than single ones, but the effect was not equal to the sum of the separate effects. There was no tendency for aureomycin-resistant mutants to appear.

Experiments with acromycin duplicated those with aureomycin.—E. M. Hume.

3000

PELLETT, P. L. and PLATT, B. S. **A dietary defect in maize developed during treatment with lime.** *Nature*, 1956, **177**, 422–424. [Human Nutrit. Res. Unit, Med. Res. Counc. Labs., Hampstead, London, N.W.3.]

When rats were given diets consisting mainly of maize cooked in lime water without supplements of vitamins of the B complex, their growth rate was significantly less than that of rats given untreated maize. Growth was improved by a supplement of aureomycin or of a mixture of B vitamins but not of nicotinic acid or tryptophan. Riboflavin produced a much greater growth improvement than vitamin B_1 and acted as well as the vitamin B complex. Analysis of the treated maize by chemical and microbiological methods showed a great decrease in content of vitamin B_1, riboflavin and total nicotinic acid. The remaining nicotinic acid might be available to a greater extent than in raw maize but the loss of vitamin B_1 and riboflavin in the process was considered to be a great disadvantage.—A. M. Copping.

3001

FARRER, K. T. H. **The nutritive value of yeast extract.** *Med. J. Austral.*, 1954, i, 67–71. [Res. Labs., Kraft Foods, Ltd., Melbourne.]

The nutritive value of yeast is reviewed. Tables are given setting out the composition, including the content of 5 B vitamins, the percentage distribution of the N between insoluble, proteose, peptone, sub-peptone and amino acid N, and the content of essential amino acids in comparison with that of meat, casein and white flour. Yeast extract provides a balanced mixture of the B vitamins and contributes especially lysine to supplement the low concentration of lysine in bread.

E. M. Hume.

3002

MONZINI, A. and CRISTALLO, G. Contenuto in vitamina B_1 e B_2 dei formaggi italiani e sue variazioni durante il processo di maturazione. [**Content of vitamins B_1 and B_2 in Italian cheeses and their variations during ripening.**] *Ann. Sper. agrar.*, 1956, **10**, 253–267. [Staz. Sper. Freddo, Milan.] English summary.

The vitamin B_1 and riboflavin contents of 11 types of Italian cheese are tabulated. Gorgonzola was the richest in both vitamins, with 68 and 432 μg. per 100 g. fresh cheese, respectively. Mascarpone, rich in fat and coagulated with acid, was a poor source of both. Bel Paese and Robiolina made with fresh milk contained about twice as much of each vitamin as when the milk was pasteurised. The vitamin contents fell slightly and then rose during the process of ripening in the last 2 cheeses, but different types of cheese varied in the behaviour of their vitamin content. Lactic acid bacteria and *Penicillium weidemannii* were shown to produce both vitamins.—D. Duncan.

3003

ALMON, L., GIEGER, M. and ANDERSON, W. S. **Effect of varied soil nitrogen on B vitamins in collards.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1235–1237. [Mississippi Agric. Exp. Stat., State College.]

Collards were grown in plots which received applications of 20, 120 or 200 lb. N per acre. Mean values are tabulated from 5 replications for yield, moisture, N, vitamin B_1, riboflavin and nicotinic acid content at the 3 levels of N application. Yield and moisture content did not significantly differ. Percentage N and vitamin content, on a dry basis, were significantly higher in collards from plots which received the medium and high applications of N compared with collards from plots which received the low application of N.—F. C. Aitken.

VITAMIN B_1 (ANEURIN, THIAMINE)

3004

DOHERTY, J. J., CANE, N. and WOKES, F. **The estimation of vitamin B_1 in pharmaceutical products.** *J. Pharm.*, 1955, **7**, 1053–1062. [Ovaltine Res. Labs., King's Langley, Herts.]

In the spectroscopic study of vitamin B_1 with changing *p*H, an isosbestic point at which there was no change in the spectral absorption over the *p*H range from 1 to 9 was found at about 273 mμ. The existence of such an isosbestic point could be used to check the production or destruction of irrelevant absorption when the *p*H was reduced from 7 to 1. Reduction of the *p*H produced a rise in the E value at 245 mμ. which for anhydrous vitamin B_1 was about 0·1 for 5 μg. per ml. Details of a method of estimation based on the finding are given.—K. H. Coward.

3005

KLOTZSCHE, C. Mikrobiologische Untersuchungen mit Aneurin-1-5-naphthalindisulfonat. [**Microbiological studies with aneurin-1-5-naphthalenedisulphonate.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102**, 429–432. [Bundesgesundheitsamt, Berlin-Dahlem.]

The 1 : 5-naphthalenedisulphonate of vitamin

B_1 is used as a stable source of the vitamin for fortifying food products. In a series of standard tests with *Phycomyces blakesleeanus*, stimulation of growth was variable in comparison with that caused by vitamin B_1 hydrochloride. Satisfactory response to the naphthalenedisulphonate was obtained only with a highly purified and washed preparation. It was suggested that some impurity might be inhibiting growth of *Phycomyces* and that the naphthalenedisulphonate should be highly purified in order to obtain its full effect as a source of vitamin B_1. Tests with lactobacilli gave irregular responses which could not be used as a measure of potency of the disulphonate.

KOEDAM, J. C., STEYN-PARVÉ, E. P. and VAN RHEENEN, D. L. **Thiamine deficiency after feeding pyrithiamine.** *Biochim. biophys. Acta*, 1956, **19,** 181–182. [Lab. Physiol. Chem., Univ. Utrecht.]

In pigeons given vitamin B_1, alone or with pyrithiamine, the inhibitor produced a highly significant decrease of vitamin B_1 pyrophosphate in the brain, liver, muscle and kidneys, and of pyruvic decarboxylase in the breast muscle. The effect of the inhibitor was biochemically like simple vitamin B_1 deficiency.—A. M. Copping.

3009

MAMEESH, M. S., SCHENDEL, H. E., NORTON, H. W. and JOHNSON, B. C. **The effect of penicillin on the thiamine requirement of the rat.** *Brit. J. Nutrition*, 1956, **10,** 23–27. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Groups of rats were given a basal diet lacking vitamin B_1, alone or with graded doses of 0·5 to 5·0 μg. vitamin B_1 per g. diet, with and without 50 mg. crystalline sodium penicillin G per kg. diet. With low intakes of vitamin B_1 growth was improved by penicillin but with larger amounts penicillin had no effect. It was calculated that for maximum growth without penicillin the rat required $1{\cdot}00 \pm 0{\cdot}03$ μg. vitamin B_1 per g. diet, and with penicillin $0{\cdot}98 \pm 0{\cdot}14$. The findings are briefly discussed with reference to theories about the effect of antibiotics on the requirements of vitamins of the B complex.—A. M. Copping.

GHELARDI PRIMAVORI, G. Contributo allo studio farmacologico dell'acido glicerofosforico. 2. Differenza di azione biologica fra i due isomeri alfa e beta associati alla tiamina od alla cocarbossilasi. [**Pharmacological study of glycerophosphoric acid. 2. Difference in biological action between the two isomers, α- and β-, associated with vitamin B_1 or cocarboxylase.**] *Arch. internat. Pharmacodyn.*, 1955–56, **104,** 228–243. [Ist. Farmacol., Univ. Pisa.]

In 8 groups of adult rabbits the excretion of phosphorus in the urine and faeces was measured after oral or parenteral administration of vitamin B_1 or cocarboxylase, and Na α- or β-glycerophosphate. When α-glycerophosphate was given with vitamin B_1 or cocarboxylase there was always a tendency to increased loss of P by excretion ; with β-glycerophosphate there was increased retention of P. When the glycerophosphates were given alone, their behaviour was reversed.

CARDOSO, M. R. Action de l'aneurine et de l'acétylcholine sur le coeur de la tortue. [**Action of vitamin B_1 and acetylcholine on the heart of the tortoise.**] *Exp. Med. Surg.*, 1955, **13,** 270–278. [Inst. Rocha Cabral, Lisbon.]

In the isolated heart of the tortoise *Clemmys leprosa*, perfused with Ringer solution, addition of a small amount of acetylcholine to the perfusion fluid caused a diminution in the frequency and amplitude of the contractions. After washing of the heart repetition of the experiment had the same effect. If, however, just before the addition of acetylcholine, vitamin B_1 was added, the effect of acetylcholine was much weaker, and further addition of acetylcholine had no effect. Such perfusion fluid tested on another heart inhibited its response to acetylcholine. Even when the first heart was washed several times after exposure to acetylcholine and vitamin B_1, perfusion fluid from it still had power to protect the second heart against acetylcholine. To produce the effect on the first heart it was necessary that vitamin B_1 and acetylcholine should act together and not in sequence, and that the temperature should be maintained at about 35° C., but it was not necessary for the second heart to be kept warm. It is concluded that a tortoise heart, made insensitive to acetylcholine by the action of vitamin B_1 and acetylcholine, liberates a substance capable of rendering a second heart insensitive.—E. M. Hume.

GIACALONE, O. Azione della aneurina sui limiti di resistenza all'ipoalimentazione e sulla perdita percentuale giornaliera di peso corporeo. [**Action of vitamin B_1 on the limits of resistance to undernutrition and on the daily percentage loss of bodyweight.**] *Arch. Fisiol.*, 1955, **55**, 68–72. [Ist. Fisiol., Univ. Palermo.]

In the same way as was done with vitamin B_{12} (Abst. 3076, Vol. 26), 2 groups of 5 adult rats were maintained on a complete diet inadequate in quantity, 0·215 Cal. per g. bodyweight being given daily. One group received 5 mg. vitamin B_1 by subcutaneous injection every other day. The rats given vitamin B_1 died after an average of 50·2 days with an average loss of 49·1 per cent. of bodyweight; the corresponding values for those not given vitamin B_1 were 54·4 and 47·4. The differences were significant.—E. M. Hume.

3013

PANDOLFO, L. and SERIO, S. Azione del blocco dei gruppi NH_2 con chetene sull' attività della tiaminasi estratta dalla *Venerupis decussata*. [**Effect of blocking the NH_2 groups with ketenes on the activity of thiaminase extracted from *Venerupis decussata*.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 541–543. [Ist. Chim. Biol., Univ. Palermo.]

Thiaminase prepared from *Venerupis decussata* was treated with ketenes prepared by heating acetone vapour. The amount of amino N in the thiaminase extract was sometimes increased and sometimes decreased by the treatment, but the thiaminase activity was in no way affected.

E. M. Hume.

HARRIS, D. L. **Interaction of thiamine and pyridoxine in *Neurospora*. 2. Competition between pyridoxine and the pyrimidine precursor of thiamine.** *Arch. Biochem. Biophys.*, 1956, **60**, 35–43. [Dept. Physiol., Univ. Chicago, Ill.]

In extension of previous studies (Abst. 2926, Vol. 23) it was found that pyridoxine inhibited the synthesis of thiamine by thiamine-less mutants of *Neurospora*. The inhibition was not readily overcome by addition of thiazole but was prevented by an increase in concentration of pyrimidine. No inhibition occurred if thiamine was present. Utilisation of pyrimidine could be inhibited by 4-deoxypyridoxine. It is suggested that pyridoxine may inhibit synthesis of thiamine by acting as a competitive substrate for the enzyme which couples pyrimidine to thiazole.—A. M. Copping.

RIBOFLAVIN

3016

FORKER, B. R. and MORGAN, A. F. **Cause of pituitary-adrenal failure in the riboflavin-deficient rat.** *J. Biol. Chem.*, 1955, **217**, 659–667. [Dept. Home Econ., Univ. California, Berkeley.]

Groups of about 8 weanling rats, given a complete diet with or without riboflavin or the complete diet restricted to give the same bodyweight as the deprived group, were exposed for $2\frac{1}{2}$ hr. to an oxygen tension equivalent to an altitude of 20,000 ft. at different ages after from 1 to 11 weeks on the diet (see Abst. 430, Vol. 25).

The ascorbic acid content of the adrenal glands generally increased progressively with lapse of time, particularly in the deprived rats; in the rats on the restricted diet it increased greatly at first but not progressively later. Rats exposed to anoxia had less ascorbic acid than corresponding unexposed rats whatever the rest of the treatment. In deprived rats the difference decreased and disappeared after 11 weeks, but it increased with time in the rats fed on the restricted diet.

The adrenal glands of normal and deprived rats were enucleated after 7 weeks on the experimental diets. The cortex was soon regenerated, as was proved by the maintenance of blood glucose values during a fast of from 4 to 7 days.

Male rats were hypophysectomised at weaning and then given riboflavin-deficient or normal diets. When signs of deficiency appeared adrenocorticotropic hormone was given and the animals were killed after some hours' fast. The fall in the eosinophil count of the blood and the rise in the glycogen content of the liver in response to the hormone were similar in deprived and normal rats but administration of adrenaline caused no eosinopenia in the deficient animals. It appeared probable that the adrenal cortex of rats deprived of riboflavin had not lost the ability to respond normally to adrenocorticotropic hormone, but that the defect might lie in failure of the process by which the pituitary is stimulated to release adrenocorticotropic hormone.—A. M. Copping.

KOTAKE, Y. and MORI, T. **Research on xanthurenic acid. 12. On the excretion of**

xanthurenic acid and the diabetic symptoms appeared in albino rats caused by vitamin B_2 deficiency. *Proc. Japan Acad.*, 1955, **31**, 247–251. [Dept. Biochem., Wakayama Med. Coll.]

For previous parts see Absts. 4903, 5617, Vol. 25.

12. Groups of 5 male rats weighing about 150 g. were given a complete purified diet or one deficient in riboflavin or in vitamin B_6. When signs of deficiency appeared, xanthurenic acid was estimated in the urine after a single oral dose of 0·1 g. tryptophan. The mean total excretion, in μg., was for non-deprived rats 1358, for those deprived of vitamin B_6 10,900, and for those deprived of riboflavin 4893. The rats deprived of riboflavin were given 10 mg. tryptophan every other day for a month. The blood sugar value rose steadily, though less steeply than with deprivation of vitamin B_6. There was some degree of degeneration in the beta cells of the pancreas, but it too was less than in rats deprived of vitamin B_6. When the deprived rats were given a single oral dose of 0·1 g. tryptophan, the blood sugar value fluctuated widely and reached a high level after 72 hr. If 1 mg. 5-hydroxyanthranilic acid was injected when the oral dose of tryptophan was given, the maximum value attained by the blood sugar was much lower.—E. M. Hume.

NELSON, M. M., BAIRD, C. D. C., WRIGHT, H. V. and EVANS, H. M. **Multiple congenital abnormalities in the rat resulting from riboflavin deficiency induced by the antimetabolite galactoflavin.** *J. Nutrition*, 1956, **58**, 125–134. [Inst. Exp. Biol., Univ. California, Berkeley.]

Simple deprivation of riboflavin during gestation did not affect foetal development in rats. When galactoflavin was added to a diet lacking riboflavin the incidence of foetal death and abnormalities was high. The effect of the antimetabolite was present with amounts per kg. diet of from 5 to 25 mg. and was severe with 50 mg. or more. Inclusion of 200 mg. in the diet for from 4 to 6 days between the seventh and thirteenth days of gestation produced abnormalities in the skeleton and cardiovascular system of the young. When galactoflavin was given throughout gestation, severe abnormalities of the skeletal and soft tissue occurred. Inclusion of 20 mg. riboflavin per kg. diet completely controlled the effect of the antimetabolite.—A. M. Copping.

EPSHTEĬN, I. B. and CHAGOVETZ, R. V. Izmeneniya soderzhaniya i raspredeleniya riboflavina v myshtzakh krolika pri rabote i narkoze. [**Changes in the total content and distribution of riboflavin in rabbit muscle during work and narcosis.**] *Dokl. Akad. Nauk SSSR*, 1955, **105**, 319–322. [Inst. Biokhim., Akad. Nauk SSSR.]

Total riboflavin and labile and tightly-bound fractions were estimated in rabbit thigh muscle fatigued with an electric stimulator for 1 hr., and, in addition, in animals narcotised with barbiturate, after stimulation until an equivalent degree of fatigue had been reached. Throughout the experiments, values for total riboflavin and for the fractions estimated were higher in fatigued than in comparable unexercised muscle. There was no difference between values in narcotised and normal animals not exercised, but values for fatigued muscle were somewhat less in narcotised than in normal muscle.—D. W. Taylor.

SCHOU, S. A. Kobberindholdet i galenica. 3. Kobberafgift fra apparatur. [**The copper content of galenicals. 3. The release of copper from apparatus.**] *Dansk. Tidsskr. Farm.*, 1955, **29**, 243–258. [Rigshosp. Apotek, Copenhagen.] English summary.

Solutions of nicotinic acid, nicotinamide, niketh-amide and theophyllamine prepared for injection were found to attack the copper and brass of apparatus for filling ampoules and syringes to an extent which could affect the stability of the preparations and could even exceed the amount known to give unpleasant effects on injection. (From summary.)—K. H. Coward.

3026

KODICEK, E., BRAUDE, R., KON, S. K. and MITCHELL, K. G. **The effect of alkaline hydrolysis of maize on the availability of its nicotinic acid to the pig.** *Brit. J. Nutrition*, 1956, **10**, 51–67. [Dunn Nutrit. Lab., Univ. Cambridge.]

Nicotinic acid, tryptophan, riboflavin, vitamin B_1 and pantothenic acid were estimated by microbiological, chemical and chromatographic methods in diets and dietary constituents given to weanling pigs. The greater part of the nicotinic acid in maize was in the milling fractions termed hominy meal and bran, where it was almost entirely in the bound form. Hydrolysis of the milling fractions with 0·5 *N* NaOH liberated nicotinic acid from its bound form, as was shown by the behaviour on a paper chromatogram. When signs of nicotinic acid deprivation appeared in pigs receiving a diet based on whole maize, recovery was induced by replacing the whole maize with maize reconstituted from milling fractions, including hominy meal and bran treated by alkaline hydrolysis. Reconstituted maize with hominy meal and bran untreated by alkali did not promote recovery. Treatment with nicotinic acid cured the lesions. Alkaline hydrolysis of maizemeal and bran is recommended as a useful method of making the vitamin available to pigs.—A. M. Copping.

3027

GERSHBEIN, L. L. **Effect of nicotinic acid and derivatives on rat liver regeneration.** *Amer. J. Physiol.*, 1956, **184**, 47–51. [Biochem. Res. Lab., Dept. Biol., Illinois Inst. Technol., Chicago.]

In rats with part of the liver removed, regeneration of liver tissue was less if the diets included 0·25 or 0·35 per cent. nicotinic acid or nicotinamide. Similar amounts of *iso*nicotinic acid hydrazide or kynurenic acid had no apparent effect, and coramine increased the rate of new tissue formation. When the nicotinic acid or amide was given in a single large daily dose by mouth or injection the rate of liver regeneration was not affected. Inclusion of 0·35 per cent. choline in the diet with 0·35 per cent. nicotinamide prevented the inhibition of liver regeneration by the nicotinamide.—A. M. Copping.

3028

SEN, S. C. and SEN, S. **Niacin and coagulability of blood.** *Indian J. Med. Res.*, 1956, **44**, 67–70. [Dept. Physiol., Presidency Coll., Calcutta.]

In 12 rabbits, after the intramuscular injection of 100 mg. nicotinic acid per kg. bodyweight, which had previously been shown to produce a big rise in blood sugar, there was an increase in the coagulability of the blood during the first 60 min. followed by a return to normal in 120 min. The ionisable calcium rose and fell correspondingly. There was no significant change in the prothrombin or fibrinogen value, but there was an increase in platelet count.—L. Wills.

DAUM, M. G. La niacina en el café y su importancia nutricional en Venezuela. [**Nicotinic acid in coffee and its nutritional importance in Venezuela.**] *Arch. venezol. Nutricion*, 1955, **6,** 61–70. [Inst. Nac. Nutrición.] English and German summaries.

Nicotinic acid was estimated microbiologically with *Lactobacillus arabinosus* in fresh and roasted coffee beans and in infusions and extracts of coffee. The nicotinic acid content increased during roasting and an average of 33·9 mg. per 100 g. roasted, ground coffee was obtained from 15 samples. More than 80 per cent. of the nicotinic acid was present in extracts and infusions and less than 20 per cent. was retained in the grounds. From the results of the study and from the known high consumption of coffee in Venezuela it was calculated that coffee supplied an average daily intake of 1·58 mg. nicotinic acid.

VITAMIN B_6 (PYRIDOXINE, ADERMIN)

3031

PARRISH, W. P., LOY, H. W. (Jr.) and KLINE, O. L. **Further studies on the yeast method for vitamin B_6.** *J. Assoc. Off. Agric. Chem.*, 1956, **39,** 157–166. [Div. Nutrit., Food Drug Admin., Dept. Health, Educat. Welfare, Washington 25, D.C.]

The use of *Saccharomyces carlsbergensis* to estimate pyridoxine, pyridoxal and pyridoxamine was investigated in relation to the *p*H and amino acid and L-cystine content of the medium. The critical *p*H for optimum growth was in the range from 3·5 to 4·5 with inorganic nitrogen supplied by 10 mg. $(NH_4)_2HPO_4$ per tube or as $(NH_4)_2SO_4$. Of 18 amino acids in a casein hydrolysate, 10 increased yeast growth and of these 5, *iso*leucine, histidine, methionine, tryptophan and valine, were essential. A high concentration of cystine tended to depress growth response to pyridoxamine. In order to obtain uniformity of response it is suggested that pyridoxamine should be converted to pyridoxine by treatment with nitrous acid.

A. M. Copping.

3032

SAKURAGI, T. and KUMMEROW, F. A. **The synthesis of long chain fatty acid derivatives of the vitamin B_6 group.** *J. Amer. Chem. Soc.*, 1956, **78,** 839–842. [Dept. Food Technol., Univ. Illinois, Urbana.]

The synthesis is described of the tripalmitate, trilinoleate, trioctanoate and tridecanoate of pyridoxine, pyridoxal dipalmitate, pyridoxamine tripalmitate and other palmitate derivatives of pyridoxine and deoxypyridoxine. All the long-chain fatty acid derivatives in ether as solvent had their maximum ultraviolet absorption in the region of 265 to 270 mμ.—A. M. Copping.

3033

SAKURAGI, T. and KUMMEROW, F. A. **Solubility and heat stability of fat-soluble derivatives of vitamin B_6.** *J. Amer. Oil Chem. Soc.*, 1956, **33,** 116–118. [Dept. Food Technol., Univ. Illinois, Urbana.]

Pyridoxine trilinoleate and tripalmitate were soluble in olive oil at 3° C. Solubility was increased by mixed esterification with palmityl and acetyl groups. Esters with C_6, C_8 or C_{10} fatty acids also were fat-soluble. The esters were stable to heat in oily solution when a palmitoyl group was present or when pyridoxine was fully esterified with a saturated fatty acid of chain length C_{10} or longer.—A. M. Copping.

3034

TULPULE, P. G. and WILLIAMS, J. N. (Jr.) **Relationship of dietary protein and food intake to pyridoxine nutrition in the rat.** *J. Nutrition*, 1955, **57,** 529–539. [Dept. Biochem., Univ. Wisconsin, Madison.]

Changes in bodyweight, vitamin B_6 activity and concentration of riboflavin in the liver, kidneys and intestines were studied in rats receiving a purified diet containing 20 per cent. casein with or without pyridoxine or diets without pyridoxine and containing 60 per cent. casein or no casein. Without pyridoxine, the high protein diet permitted slightly better weight gain than the 20 per cent. casein diet, but the loss of vitamin B_6 and riboflavin from the tissues was similar on the two diets. Restriction of food intake on the diet with 20 per cent. casein and devoid of pyridoxine caused loss of vitamin B_6 from the tissues similar to that on the unrestricted diet. When the diet contained no protein the loss of vitamin B_6 was less and that of riboflavin greater than with diets containing 20

or 60 per cent. casein. After 4 weeks some animals in the groups deprived of pyridoxine were given the complete purified diet and the vitamin B_6 activity of their tissues rose to normal within 2 weeks.—A. M. Copping.

3035

AGNEW, L. R. C. **Cardiac, renal and hepatic hypertrophy in pyridoxine-deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 452–453. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The heart and kidneys from rats receiving for 55 days a purified diet lacking pyridoxine had significantly greater weights, both wet and dry, than those from rats having the same diet supplemented with pyridoxine, whether the food intake was unrestricted or restricted to give bodyweights equal to those of the deprived rats. The livers of the deprived rats were significantly heavier than those of the non-deprived with restricted intake, but were not significantly different from those of the non-deprived with unrestricted intake. The increase in weight of the heart, liver and kidneys was therefore considered to be a true hypertrophy. A. M. Copping.

3036

MEISTER, A. and DOWNEY, P. F. **Evidence for participation of vit. B_6 in glutamine-α-keto acid transamination-deamidation reaction.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 49–52. [Lab. Biochem., Nat. Cancer Inst., Nat. Insts. Health, Bethesda, Md.]

Large doses of *iso*nicotinic acid hydrazide given by stomach tube or in drinking water for from 10 to 20 days reduced the glutamine-pyruvate transaminase and deamidase activity *in vitro* of liver tissue preparations from rats on a normal stock diet or a purified diet lacking vitamin B_6. Addition to the liver preparations of pyridoxal phosphate or pyridoxamine phosphate increased the activity of preparations from rats receiving *iso*nicotinic hydrazide but not of preparations from untreated rats. The results supported the theory that vitamin B_6 is involved in the mechanism of transamination between glutamine and α-keto acids.—A. M. Copping.

3037

KOTAKE, Y. and NAGAYAMA, I. **Research on xanthurenic acid. 13. The effects of xanthurenic acid on phosphorus metabolism.** *Proc. Japan Acad.*, 1955, **31,** 311–316. [Dept. Biochem., Wakayama Med. Coll.]

For part 12 see Abst. 3017, Vol. 26.

Of rats weighing about 200 g., fed on a diet of, per cent., casein 22, starch 52, yeast 2, agar 3, McCollum salt mixture 6, sugar 5 and butter 10, some were injected intraperitoneally with 300 mg. xanthurenic acid per kg. bodyweight. The values for blood sugar and for inorganic P in the blood and liver all rose but began to fall again within 5 hr. Phosphocreatine in the blood and liver fell but began to rise again within 3 hr. None of the values had been restored to the initial level within 14 days. The amount of creatinine in the urine in 24 hr. increased. When groups of rats were given a casein diet and a small amount of tryptophan, with 35 per cent. butter or deficient in vitamin B_6, the same changes were induced. When glucose was given to the experimental groups just described, blood sugar increased but the value for inorganic P in the blood remained almost unchanged, although in untreated rats it fell steeply.

In diabetic patients after injection of glucose, the rise in blood sugar was not accompanied by the fall in inorganic P shown by healthy subjects.

Rats were injected simultaneously with 0·2 unit insulin, and 300 mg. xanthurenic acid per kg. bodyweight. They were killed after 2 or 3 hr. The fall in the values for phosphocreatine in the blood and liver which occurs with xanthurenic acid was prevented by insulin.

It is concluded that xanthurenic acid acts to produce diabetes by blocking the phosphorylation of carbonate.—E. M. Hume.

3038

GEROCARNI, B. and CALDARERA, C. Dati preliminari sopra un'esperienza di sinergismo fra cortisone e vitamina B_6. [**Preliminary results on a test for synergism between cortisone and vitamin B_6.**] *Acta vitaminol.*, 1955, **9,** 261–263. [Fac. Méd., Paris.] French, English, German and Spanish summaries.

Formalin arthritis was induced in male rats weighing about 150 g. by injection into the plantar aponeurosis of the foot of 0·1 ml. of 2 per cent. formalin twice on alternate days, and, after 5 days, of 4 per cent. formalin once. Four groups of 5 rats thus prepared were given by intramuscular injection daily for 30 days 2·5 mg. cortisone acetate, or the same with 6 mg. daily of pyridoxine diphosphate, or physiological saline, or were untreated. Cortisone considerably modified the development of the lesions, and its beneficial effect was enhanced when pyridoxine diphosphate was given as well.—E. M. Hume.

BOXER, G. E., SHONK, C. E., STOERK, H. C., BIELINSKI, T. C. and BUDZILOVICH, T. V. **Pantoylaminoethanethiol, an antagonist of pantothenic acid and pantetheine active *in vitro* and in the rat.** *J. Biol. Chem.*, 1955, **217,** 541–550. [Res. Labs., Chem. Div., Merck and Co., Inc., Rahway, N.J.]

The acetylation of sulphanilamide by a crude pigeon liver extract in the presence of coenzyme A or pantotheine, the precursor of coenzyme A, was inhibited by pantoylaminoethanethiol added to the system. The direct effect of the antagonist on coenzyme A, shown by an inhibition of phosphotransacetylase, was less than on the system synthesising coenzyme A.

In rats deprived of pantothenic acid, addition of the antagonist to the diet caused failure of growth and death within 3 weeks. The effect was reversed by pantothenic acid. The coenzyme A content of liver and brain decreased in rats receiving the antagonist. Less than 10 mg. of antagonist daily had little effect on rats; reversal of inhibition was obtained with 90 μg. pantothenic acid daily, and less gave incomplete protection.

ULLREY, D. E., BECKER, D. E., TERRILL, S. W. and NOTZOLD, R. A. **Dietary levels of pantothenic acid and reproductive performance of female swine.** *J. Nutrition*, 1955, **57,** 401–414. [Illinois Agric. Exp. Stat., Urbana.]

Reproductive performance was investigated in 16 Duroc and 16 Hampshire gilts receiving a basal diet containing soya bean protein with vitamin supplements including 1·5, 5·9, 12·5 or 19·1 mg. pantothenic acid per kg. diet. The groups having the 2 lower doses of pantothenic acid showed signs of deficiency; fatty livers, enlarged adrenal glands, intramuscular haemorrhage, dilatation of the heart, atrophy of the ovaries and failure of uterine development were recorded at autopsy. Those on the lowest dose failed to conceive. Those having 5·9 mg. pantothenic acid per kg. diet carried their litters to term but the young showed abnormalities, including locomotor incoordination, and more than half died within 14 days. With 12·5 or 19·1 mg. pantothenic acid per kg. diet, gestation and lactation appeared to be normal and there was no difference between the 2 groups. Gilts receiving 5·9 mg. vitamin per kg. diet had significantly less free pantothenic acid in the milk collected during the third and fourth weeks of lactation than those having higher intakes. There was no significant difference in the amount of total pantothenic acid in the milk whatever the level of feeding.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

3045

TIKHOMIROVA, A. N. and PENAR, O. I. Materialy k izucheniyu obmena folievoi kisloty u belykh krys pri razvitii u nikh nedostatochnosti etoi kisloty. [**Folic acid metabolism in the rat during the development of folic acid deficiency.**] *Vop. Pitan.*, 1956, **15,** No. 1, 37–40. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Twenty weanling rats weighing from 50 to 60 g. received a synthetic diet with little or no folic acid and containing 1 per cent. sulphonamide. Half the rats received 200 μg. folic acid daily. At intervals for from 5 to 6 weeks folic acid was estimated in 24-hr. samples of urine, and the blood picture was studied. The quantities of sulphonamide and of folic acid given were then doubled and the rats were killed 2 or 3 weeks later for estimation of folic acid in the liver.

The rats not given folic acid gained little weight after the 20th day. The mean daily folic acid output in the urine fell in the deprived group from 102 to 61 μg. by the fifth week and rose in the non-deprived from 92 to 139 μg. Hb value and reticulocyte and white cell counts fell steadily in the deprived rats. The total folic acid content of the liver at the end of the experiment was 20 μg. in the deprived and 122 μg. in the non-deprived rats.

McDONALD, M. W. **Effect of supplementary choline and methionine on the response of chickens to folic acid.** *Nature*, 1956, **177,** 343. [Poultry Exp. Stat., Seven Hills, N.S.W.]

Chicks were given for 6 weeks a basal diet of crushed wheat, meatmeal and whey powder with or without folic acid or *dl*-methionine or both. In a second experiment the diet was supplemented with choline or folic acid or choline, folic acid and methionine. In the first experiment growth was increased by methionine and still more by methionine and folic acid, but folic acid alone gave no increase, showing that the chick's requirement for folic acid was increased by methionine. In the second experiment growth was depressed by choline, but the response was reversed when folic acid was given also. The results showed that the basal diet was deficient in methionine and that the response to its addition was independent of its role as methyl donor. It is suggested that the interaction between methionine and folic acid in the first experiment was due to the labile methyl group in the molecule. The results showed that folic acid is required for the catabolism of excess methyl groups as well as for transmethylation.

SLUNGAARD, R. K. and HIGGINS, G. M. **Experimental megaloblastic anemia in young guinea pigs.** *Blood, J. Haematol.*, 1956, **11,** 123–142. [Mayo Clin., Rochester, Minn.]

Guineapigs fed on a purified complete diet were maintained in good health and their blood picture was normal. When vitamin C, folic acid or vitamin B_{12} or a combination of them was removed from the diet, certain animals developed megaloblastosis in each group except that from which vitamin C alone was removed. The vitamin-C-deficient animals developed hypochromic, microcytic anaemia associated with internal haemorrhages. Megaloblasts and giant metamyelocytes in the bone marrow were found most frequently in animals deprived of both vitamin C and folic acid, and only infrequently in animals deprived of vitamin B_{12} alone or with vitamin C. Most, but not all, of the animals with megaloblastosis were anaemic ; the anaemia was frequently dimorphic. The clinical condition of the animal was not a reliable guide to the presence of megaloblastosis, but diarrhoea was associated with megaloblastosis in animals deficient in folic acid, alone or combined with vitamin C. The bacterial flora of the stools was examined but gave inconclusive results, though there was some evidence that the presence of *Bacterium coli*, not normally found in the stools of guineapigs, was associated with the development of megaloblastosis. Spontaneous remissions occurred. In 2 animals deprived of both vitamin C and folic acid treatment with vitamin C had no effect on the megaloblastosis or the anaemia, but folic acid produced a return to normal. Each group of animals and often individual animals are described in detail.

GUGGENHEIM, K., HALEVY, S., NEUMANN, H. and USIELI, V. **The metabolism of pteroylglutamic acid by the rat.** *Biochem. J.*, 1956, **62,** 281–286. [Lab. Nutrit., Dept. Biochem., Hebrew Univ.-Hadassah Med. Sch., Jerusalem.]

Excretion of folic acid and citrovorum factor in the urine and storage in the liver in response to injection of pteroylglutamic acid with or without ascorbic acid were studied in young rats on an adequate synthetic diet and on diets high in fat, low in protein and fat, low in protein and high in fat, or protein-free. Urinary excretion of folic acid and citrovorum factor was increased by giving pteroylglutamic acid and much increased by the addition of ascorbic acid. Citrovorum factor accounted for only 0·5 to 3 per cent. of

the total folic acid activity. The livers of rats receiving pteroylglutamic acid showed considerable storage of citrovorum factor and folic acid. The amount of citrovorum factor appeared to be limited; that of folic acid increased with increased dosage of pteroylglutamic acid and ascorbic acid. Rats receiving phenobarbital showed increased excretion of citrovorum factor and of ascorbic acid. Addition of ascorbic acid to urine *in vitro* did not increase the content of citrovorum factor. Low protein intake decreased the amount of citrovorum factor in the liver, and with no protein the ability to store folic acid also was impaired. High fat intake or accumulation of fat in the liver did not appear to affect ability to form and store citrovorum factor.

A. M. Copping.

FERRARI, V. La conversione dell'acido folico a "Citrovorum Factor" nelle epatopatie sperimentali e cliniche. 1. Ricerche sperimentali in vivo. [**Conversion of folic acid to citrovorum factor in experimental and clinical liver disorders. 1. Experiments *in vivo*.**] *Acta vitaminol.*, 1955, **9**, 241–245. [Ist. Patol. Med., Univ. Pavia.] French, English, German and Spanish summaries.

Six adult male rats weighing from 300 to 350 g. were selected from a group treated for 4 months with CCl_4 and were matched with 6 normal rats of similar age, strain and weight. For a week before the experiment they received a basal diet containing, per cent., washed casein 18, rice starch 68, olive oil 10 and salt mixture 4, with vitamin B_1, riboflavin, vitamin B_6, nicotinamide, calcium pantothenate, *p*-aminobenzoic acid, biotin, inositol, choline, menadione, calciferol and 0·2 mg. folic acid per kg. diet. Vitamin A was given weekly. Urine was collected for 24 hr. before and after intraperitoneal injection of 1 mg. folic acid, and total folic acid and citrovorum factor were estimated microbiologically.

There was no significant difference in basal excretion of citrovorum factor between rats treated with CCl_4 and untreated rats, but after administration of folic acid the untreated rats excreted significantly more citrovorum factor than the treated. The total folic acid activity of the urine, measured after the test dose in 2 rats of each group, showed no significant difference between the groups. It is suggested that the difference in output of citrovorum factor was due to impairment of the conversion of folic acid by the damaged liver.—D. Duncan.

3050

GOLDIN, A., VENDITTI, J. M., HUMPHREYS, S. R., DENNIS, D. and MANTEL, N. **Studies on the management of mouse leukemia (L1210) with antagonists of folic acid.** *Cancer Res.*, 1955, **15**, 742–747. [Lab. Chem. Pharmacol., Nat. Cancer Inst., Bethesda, Md.]

In an experiment with 17 groups of 20 mice inoculated with leucaemia L1210 the effects of varying amounts of aminopterin or A-methopterin with and without delayed addition of citrovorum factor were studied. The survival time of the mice was considerably extended by the folic acid antagonists in suitable amounts. When citrovorum factor was given after the antagonists the dose could be very large without lethal effect. In a second experiment, survival time was much prolonged with carefully chosen doses of A-methopterin and citrovorum factor. Leucaemic cells from mice which survived long periods of treatment did not appear to develop resistance to the folic acid antagonist. The effect of treatment seemed to depend on some relation between tumour, host and drug which is not yet fully defined.

FOLEY, G. E. and HALEY, E. C. **Chemical and biological studies on 1, 2-dihydro-*s*-triazines. 7. Activity in pteroylglutamic acid-*Lactobacillus casei* 7469 systems. 8. Activity in nicotinic acid, riboflavin and thiamine systems. 9. Inhibition of synthesis of citrovorum factor in *Leuconostoc citrovorum* 8081 systems.**

FOLEY, G. E., MODEST, E. J., FARBER, S. and HALEY, E. C. **10. Mechanism of action in microbiological systems.** *Antonie van Leeuwenhoek J. Microbiol. Serol.*, 1955, **21**, 385–396; 397–404; 405–416; 417–432. [Dept. Pathol., Harvard Med. Sch., Boston, Mass.]

7. The 1 : 2-dihydro-*s*-triazines are inhibitors of *Lactobacillus casei* 7469 in systems for estimating pteroylglutamic acid. The behaviour of a number of derivatives was studied.

8. In the same way the action of derivatives was studied for inhibiting *Lactobacillus arabinosus* 8014, *L. casei* 7469 and *L. fermenti* 9338 in nicotinic acid, riboflavin and vitamin B_1 systems.

9. Low concentrations of pteroylglutamic acid which induced only a small amount of growth in *Leuconostoc citrovorum* 8081 promoted maximum growth when high concentrations of ascorbic acid were added; synthesis of citrovorum factor was affected in the same way. Other reducing agents such as glutathione or *l*-cysteine, and vitamin B_{12} and thymidine could replace ascorbic acid. Reduced (dihydro) pteroylglutamic acid acted like pteroylglutamic acid and a reducing agent. The synthesis of citrovorum factor was inhibited by 1 : 2-dihydro-*s*-triazines.

10. The evidence is marshalled in favour of the suggestion that the principal point of activity of the phenyldihydrotriazines in microbiological

systems is at the reductive sequence in the biosynthesis of citrovorum factor from pteroylglutamic acid.—E. M. Hume.

3052

NURMIKKO, V. **The dialysis technique in the study of the vitamins and amino acids affecting associations of micro-organisms.** *Acta chem. scand.*, 1955, **9**, 1317–1322. [Biochem. Inst., Helsinki.]

An apparatus was devised containing several compartments separated by dialysis membranes in which interdependence of micro-organisms for certain nutrients could be demonstrated. *Streptococcus faecalis* R, *Lactobacillus arabinosus* 17–5 and *Leuconostoc mesenteroides* P–60 could not grow in separate test tubes in a medium without phenylalanine, proline and folic acid, but could grow when they were inoculated into separate compartments of a cross-dialysis apparatus containing the same deficient medium. Experiments with up to 7 different organisms were used to demonstrate that the substances concerned in such symbiosis were phenylalanine, proline, folic acid and folinic acid.

VITAMIN B_{12}

3053

ANALYTICAL METHODS COMMITTEE, VITAMIN-B_{12} PANEL. **The estimation of vitamin B_{12}.** *Analyst*, 1956, **81**, 132–136.

The microbiological method of estimating vitamin B_{12} with *Ochromonas malhamensis* was investigated in 8 laboratories with solutions of vitamin B_{12}, 2 liver powders, fish solubles, chick mash and dried cow manure. The response of *Ochromonas* was considered to be highly specific for vitamin B_{12}, and satisfactory agreement was obtained between the different laboratories. In an appendix to the report details are given of methods for preparing test extracts and basal medium and for setting up and interpreting the tests.

A. M. Copping.

3054

SHRIMPTON, D. H. **The estimation of vitamin-B_{12} activity in feeding stuffs with *Lactobacillus leichmannii* and *Ochromonas malhamensis*.** *Analyst*, 1956, **81**, 94–99. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Vitamin B_{12} activity was estimated in herring-meal, whalemeat meal, meat-and-bone meal, dried skimmed milk and white-fish meal with *Lactobacillus leichmannii* and *Ochromonas malhamensis*. The values obtained with *Ochromonas* were like or less than those with *L. leichmannii*. No technical advantage was found in using *Ochromonas* instead of *L. leichmannii*.—A. M. Copping.

3055

HEINRICH, H. C., RÄDEL, G. and SOMMER, L. Die mikrobiologische Bestimmung der B_{12}-Vitamine mit dem Phytoflagellaten "Euglena gracilis isol. T". [**Microbiological estimation of vitamin B_{12} with the phytoflagellate *Euglena gracilis isol.* T.**] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1955, **7**, 124–127. [Physiol. Chem. Inst., Univ. Hamburg.]

A recently identified strain of *Euglena gracilis* (*E. gracilis* var. *saccharophila isol.* T) proved more satisfactory than *E. gracilis* var. *bacillaris* (Egvb.), commonly used. The newly isolated strain gave results more rapidly than the old, and the curve of response to vitamin B_{12} extended over a wider range of doses.—E. M. Hume.

3056

MCLAUGHLAN, J. M., ROGERS, C. G. and CAMPBELL, J. A. **The influence of thiamine on the microbiological assay of vitamin B_{12} with *Escherichia coli* 113-3.** *J. Amer. Pharm. Assoc.*, 1955, **44**, 594–598. [Food and Drug Lab., Dept. Nat. Health Welfare, Ottawa.]

The low results of tube tests for vitamin B_{12} in multivitamin preparations with *Bacterium coli* 113–3 and the medium of Davis and Mingioli (*J. Bacteriol.*, 1950, **60**, 17) in comparison with those of the U.S.P. method were found to be caused by the presence of vitamin B_1. When samples were extracted with sodium metabisulphite to destroy vitamin B_1, the results of the two methods agreed well.—K. H. Coward.

3057

WEISS, W., EDELSON, H. and LOY, H. W. **The nature of the dose-response curve and its effect upon the error of the assay of vitamin B_{12}.** *J. Assoc. Off. Agric. Chem.*, 1956, **39**, 167–172. [Food Drug Admin., Dept. Health, Educat. Welfare, Washington 25, D.C.]

Results of duplicate estimations on 16 samples of vitamin B_{12} made according to the U.S. Pharmacopeia XV method were analysed and discussed with reference to the shape of the curve relating dose and response and to the limits of accuracy of the method.—A. M. Copping.

nowych pochodnych witaminu B_{12}. [**2. Synthesis of new vitamin B_{12} derivatives.**]

PAWEŁKIEWICZ, J. 3. Wpływ działania aureomycyny na syntezę witaminów grupy B_{12} przez bakterie kwasu propionowego. [**3. Effect of aureomycin on the synthesis of B_{12} vitamins by propionic acid bacteria.**] *Acta biochim. polon.*, 1955, **2**, 259–278; 321–327. [Zakł. Biochemii Żywności WSR, Poznan.] English and Russian summaries.

For previous work see Abst. 4950, Vol. 25.

2. Six further new substances synthesised by *Propionibacterium shermani* were isolated. Instead of the 5 : 6-dimethylbenzimidazole of vitamin B_{12}, they contained, as nucleotide bases, benzimidazole, 5-nitrobenzimidazole, 5(6)-nitro-6(5)-methylbenzimidazole, 5 : 6-di-nitrobenzimidazole, 5-ethoxybenzimidazole and 5 : 6-imidazobenzimidazole. All were obtained in crystalline form. The propionic acid bacteria condensed benzotriazole and 2-mercaptobenzomidazole with the cobalamin molecule. The 6 substances were active for *Bacterium coli* mutant and for *Euglena gracilis*. The synthesis of cyanocobalamin followed the synthesis of cyanocobalamin desnucleotide (vitamin B_{12p}); it took place in the course of 24 hr. in the final stage of fermentation, in the presence of 5 : 6-dimethylbenzimidazole.

3. Addition of aureomycin to the culture of *Propionibacterium* changed the proportions of the different cobalamins synthesised. The concentration of vitamin B_{12} and of an unidentified cobalamin X increased and that of vitamin B_{12p} decreased. (From summaries.)—E. M. Hume.

3059

JANICKI, J. and PAWEŁKIEWICZ, J. Witamin B_{12p}. [**Vitamin B_{12p}.**] *Acta biochim. polon.*, 1955, **2**, 329–341. [Zakł. Biochemii Żyności WSR, Poznan.] Russian and English summaries.

The cobalamin previously isolated and called vitamin B_{12p} (Abst. 4950, Vol. 25) has been identified as cyanocobalamin desnucleotide and is considered to be identical with Ford's Factor B (Abst. 1839, Vol. 24). A chromatographic method with aluminium oxide was developed for separating vitamin B_{12p} from other cobalamins in 85 per cent. acetone solution. In the crude concentrate of cobalamins from the propionic acid bacterial fermentation, vitamin B_{12p} constituted from 10 to 15 per cent. (From summary.)—E. M. Hume.

3060

OSTROWSKI, W. Połączenia witaminu B_{12} z białkami. 3. Badania nad kompleksem cyjanokobalamina-białko (erytroglobulin) w surowicy krwi. [**Protein-vitamin B_{12} complexes. 3. Studies of the cyanocobalamin-protein complex (erythroglobulin) in blood serum.**] *Acta biochim. polon.*, 1955, **2**, 297–313. [Zakł. Chemii Fizjol. AM, Cracow.] English and Russian summaries.

For previous work see Abst. 444, Vol. 26.

3. The cyanocobalamin-protein complex was precipitated from fraction III of human serum by Cohn's ethanol method (*J. Amer. Chem. Soc.*, 1950, **72**, 465). In fraction IV the amount was only about one-third of that in fraction III. Cyanocobalamin was estimated with *Euglena gracilis*. In precipitation of bovine serum proteins insoluble in water, the complex was with the α-euglobulin fraction soluble in 0·01 *M* NaCl. The complex separated from serum fractionated by Derrien's method (Abst. 1515, Vol. 22) in ammonium sulphate solvent from 1·46 *M* to 1·96 *M*, so that its solubility resembled that of the α-globulin group. It was adsorbed on pulverised silica gel and to a less extent on Bentonite and kaolin. It was not adsorbed on Celite. The complex was stable in 0·04 *M* Britton-Robinson buffer with *p*H range from 6·5 to 8·7. Outside that range the vitamin was split off.

A chromatographic method is described, suitable for investigating free and bound vitamin B_{12} in different biological materials. (From summary.)

E. M. Hume.

3061

RÁBEK, V. T., KAŠÍK, D., ŠÍCHOVÁ, O. and ŠTĚDRÁ, H. **New members of the vitamin B_{12} group isolated from sewage sludge.** *Biochim. biophys. Acta*, 1956, **19**, 191–192. [Pharmaceut. Biochem. Inst., Prague.]

Vitamin B_{12} compounds in extracts of sewage sludge were identified by chromatography and electrophoresis on paper. Three new components, K, J and L, were shown in the chromatograms, with the possibility of a fourth, M. All were without effect on growth of *Bacterium coli* mutant.

A. M. Copping.

3062

PETERSON, B. H., HALL, B. and BIRD, O. D. **Microbiological activities of compounds related to vitamin B_{12}.** *J. Bacteriol.*, 1956, **71**, 91–93. [Res. Labs., Parke, Davis and Co., Detroit, Mich.]

The relative activities of 9 analogues of vitamin B_{12} were estimated with 3 lactobacilli, *Bacterium coli* and *Ochromonas malhamensis*. A linear response to all the analogues was obtained with *Lactobacillus leichmannii*; none of the compounds were active for *Ochromonas*. All the analogues except Factor B contained a purine base, and the microbiological activities for different organisms proved useful in separating compounds with closely similar chemical and physical properties.

A. M. Copping.

3063

JOHNSON, R. R., BENTLEY, O. G. and MOXON, A. L. **Synthesis *in vitro* and *in vivo* of Co^{60} containing vitamin B^{12}-active substances by rumen microorganisms.** *J. Biol. Chem.*, 1956, **218**, 379–390. [Dept. Animal Sci., Ohio Agric. Exp. Stat., Wooster.]

Rumen micro-organisms were grown *in vitro* in a semipurified medium with cobalt chloride containing ^{60}Co, and studies were made with a wether lamb in a metabolism crate, to which injections of ^{60}Co were given directly into the rumen through a long hypodermic needle. Substances with vitamin B_{12} activity were detected with *Lactobacillus leichmannii* and *Bacterium coli*, in fractions separated by paper electrophoresis from extracts of rumen contents or cultures ; 7 were obtained which contained ^{60}Co. Vitamin B_{12} and vitamin B_{12b} were identified, but it was calculated that up to 65 per cent. of the total radio-activity of the rumen extracts came from other forms of vitamin B_{12}.

Liver and kidney samples from the lamb showed the presence of 4 substances with vitamin B_{12} activity.—A. M. Copping.

The valency of the cobalt atom in a reduction product of vitamin B_{12} was investigated by magnetic methods. In the product, which was prepared by the method of Schindler (Abst. 3494, Vol. 21), the cobalt atom appeared to be bivalent. A. M. Copping.

3066

BEAVEN, G. H. and JOHNSON, E. A. **The reduction of vitamin B_{12}.** *Nature*, 1955, **176**, 1264–1265. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

The structure of reduction products of vitamin B_{12} was investigated by spectrophotometry. Those reported by Diehl and Murie (*Iowa State Coll. J. Sci.*, 1952, **26**, 555) and by Boos *et al.* (Abst. 4343, Vol. 23) were prepared. Both were readily re-oxidised to vitamin B_{12a}, but their spectra were widely different. Chemical behaviour suggested that the organic part of the molecule was not significantly affected and that the changes concerned the state of oxidation of the cobalt, but the spectra suggested that some rearrangement of double bonds might occur. The observations are discussed with reference to the structure of vitamin B_{12}.—A. M. Copping.

ROBSCHEIT-ROBBINS, F. S. and WHIPPLE, G. H. **Red cell stroma in dogs. Stroma protein and stroma lipides vary in different types of anemia.**

TISHKOFF, G. H., YUILE, C. L., ROBSCHEIT-ROBBINS, F. S. and WHIPPLE, G. H. **Red cell stroma and hemoglobin metabolism in anemic dogs. Regeneration of red cell proteins labeled with C^{14} lysine.**

WHIPPLE, G. H., ROBSCHEIT-ROBBINS, F. S. and BALE, W. F. **Red cell stroma protein rich in vitamin B_{12} during active regeneration. Anemia studies using radio-active cobalt B_{12} in dogs.** *J. Exp. Med.*, 1955, **102**, 705–711 ; 713–723 ; 725–731. [Dept. Pathol., Sch. Med. Dent., Univ. Rochester, N.Y.]

(*a*) Stroma is defined as the " posthemolytic residue " from washed red cells got by " agglutination " with acetate buffer solution, separation and repeated washing. For the technique see Tishkoff *et al.* (*Blood, J. Hematol.*, 1953, **8**, 459). Dogs were fed on the standard diet of salmon-bread, dried skimmed milk and tinned salmon. The stroma from blood of dogs made anaemic by bleeding contained more protein and more lipid than the residue from normal blood cells. Protein deficiency induced after bleeding did not affect the result, but dogs made anaemic while on a low-protein diet produced stroma with less protein. In phenylhydrazine anaemia, stroma protein was greatly increased.

(*b*) Dogs made anaemic as described above were given a regenerating diet which included cooked pig liver with the low-protein diet or with the salmon-bread diet alone or with Lextron and iron. In the animals rendered anaemic by bleeding the peak of incorporation of ^{14}C-lysine into the stroma preceded and exceeded the peak for Hb when liver alone was added to the diets, but followed and was lower than the peak for Hb when iron and Lextron, substances favouring the formation of Hb, also were added. In phenylhydrazine anaemia, in which Hb-forming materials are readily available to the body, the peak of incorporation in Hb preceded and exceeded that of stroma. After the peaks of incorporation had been reached the proteins of stroma and red cell Hb showed some degree of independence as far as incorporation of ^{14}C-lysine was concerned until maturation of the red cell was complete, that is to say until the end of the reticulocyte stage, when the rate of decline in the ^{14}C-lysine activity of the proteins was about the same. It is suggested that the findings show that after maturation of the red cells their proteins are metabolically inert.

(*c*) Two dogs, anaemic and given a regenerating diet, received 2 injections of vitamin B_{12} labelled with ^{60}Co at the start of treatment. The stroma protein showed a high concentration of vitamin B_{12} during the early stages of regeneration only; the Hb contained negligible amounts at all times although the content of radio-active Co in the organs lasted for many weeks after vitamin B_{12} had disappeared from the stroma.—L. Wills.

O'Dell, B. L., Gordon, J. S., Bruemmer, J. H. and Hogan, A. G. **Effect of a vitamin B_{12} deficiency and of fasting on oxidative enzymes in the rat.** *J. Biol. Chem.*, 1955, **217**, 625–630. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

Endogenous respiration, choline oxidase, succinoxidase and cytochrome oxidase were measured in the liver of newborn rats from mothers deprived of vitamin B_{12}. There was a lower content of cytochrome oxidase but not of other oxidative enzyme systems, compared with those in the liver of young born to mothers having vitamin B_{12}. There was no difference in the cytochrome oxidase of the brain, kidney and skeletal muscle between newborn rats from deprived and normal mothers. The effect on newborn rats of fasting for 24 hr. was investigated, but the decrease in cytochrome oxidase was less than in rats deprived of vitamin B_{12}. In young growing rats deprivation of vitamin B_{12} caused a decrease in the cytochrome oxidase of the liver to much the same extent as in newborn animals.—A. M. Copping.

Wong, W. T. and Schweigert, B. S. **Role of vitamin B_{12} in nucleic acid metabolism. 2. Liver coenzyme A levels in the rat.** *Arch. Biochem. Biophys.*, 1956, **60**, 126–129. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

Weanling rats from mothers deprived of vitamin B_{12} were given a diet of maize and soya bean oilmeal with or without a supplement of vitamin B_{12}. After 6 weeks the animals were killed by bleeding and the coenzyme A activity of the liver was measured by the sulphanilamide method (Abst. 1921, Vol. 18). The amount in the livers of deprived rats was from 2 to 3 times as great as in the livers of rats having vitamin B_{12}.

Henry, K. M. and Kon, S. K. **Vitamin B_{12} and protein metabolism.** *Brit. J. Nutrition*, 1956, **10**, 39–50. [Nat. Inst. Res. Dairying, Univ. Reading.]

The biological value and true digestibility of proteins were measured in a series of 8 experiments with rats depleted of vitamin B_{12} and 6 experiments with normal rats. The proteins studied were purified casein and the proteins of 100 per cent. wheat flour. Additions of DL-methionine, homocysteine or lysine were made in some experiments. For rats deprived of vitamin B_{12} methionine alone or homocysteine and vitamin B_{12} increased the biological value of casein to the same extent, indicating that the vitamin was concerned in the synthesis of methyl groups. Choline with homocysteine had the same effect as vitamin B_{12}. In 2 out of 3 experiments vitamin B_{12} alone did not improve the biological value of casein. The vitamin did not increase the biological value of the proteins of whole wheat flour. When supplements of lysine or lysine and methionine were given, the protein efficiency ratio of flour was increased by vitamin B_{12}, but this result was considered of doubtful value since it depended on the composition of the weight gain in relation to protein intake.

With normal rats addition of vitamin B_{12} did not increase the biological value of soya protein or of casein at a level of 16 per cent. protein in the diet. Vitamin B_{12} had no effect on the protein efficiency ratio of whole wheat flour for normal rats.

From these results and an extensive survey of other investigations it was concluded that vitamin B_{12} is concerned in the synthesis of methyl groups but that it does not function in transmethylation or in protein utilisation.

ARNSTEIN, H. R. V. and STANKOVIĆ, V. **The effect of certain vitamin deficiencies on glycine biosynthesis.** *Biochem. J.*, 1956, **62**, 190–198. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

Amino acid metabolism was studied in rats having purified diets with or without pteroylglutamic acid or vitamin B_{12} and in guineapigs on normal or scorbutogenic diets. Known amounts of glycine labelled with ^{15}N or ^{14}C were present in the diet and the extent of synthesis of glycine was calculated from the dilution of radio-active glycine in the viscera after from 13 to 21 days. Glycine was synthesised at a normal rate by rats deprived of vitamin B_{12} and guineapigs deprived of vitamin C. Lack of vitamin C had no effect on synthesis of hippuric acid and formate from serine. In rats deprived of pteroylglutamic acid there was a decrease in synthesis of glycine and in conversion of glycine to serine, alanine, aspartic acid and glutamic acid.—A. M. Copping.

3075

SURE, B. **Effect of amino acid and vitamin B_{12} supplements on the biologic value of proteins in rice and wheat.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 1232–1234. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

The biological value of protein in milled rice and enriched wheat flour was calculated in terms of gain in bodyweight per g. protein intake by young growing rats. Rice protein was greatly improved by the addition of L-lysine and DL-threonine together but not by lysine or vitamin B_{12} alone, which were of little effect or were inhibitory. It was further improved by vitamin B_{12} or DL-methionine in addition to L-lysine and DL-methionine. The best results, with increases of protein efficiency of 91 and 102 per cent. for polished and processed milled rice, respectively, were obtained with lysine, threonine and methionine. The percentage increase of protein efficiency in wheat flour was with lysine alone 147, lysine and threonine 206, lysine, threonine and DL-valine 222. With vitamin B_{12} the two last values increased to 241 and 252. A. M. Copping.

GIACALONE, O. Azione della vitamina B_{12} sui limiti di resistenza all'ipoalimentazione e sulla perdita percentuale giornaliera di peso corporeo. [**Action of vitamin B_{12} on the limits of resistance to undernutrition and on the daily percentage loss of bodyweight.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 545–548. [Ist. Fisiol., Univ. Palermo.]

Two groups of 5 rats were given 0·215 Cal. per g. bodyweight daily of a diet of wheat starch 75, casein 10, butter 10 and salt mixture 5, with adequate vitamins. On alternate days one group received 8 μg. vitamin B_{12} subcutaneously. The rats given vitamin B_{12} survived on the average for 52·0 days, and those not given it for 54·4 days, and the respective mean loss of weight was 91 and 89 g., differences found to be significant. (See also Abst. 4844, Vol. 25.)—E. M. Hume.

3077

TOMODA, I. **Influence of vitamin B_{12a} on the activity of perfused toad heart poisoned by cyanide.** *Kumamoto Med. J.*, 1955, **8**, 23–25. [Inst. Physiol., Coll. Med., Kumamoto Univ.]

KCN added to the perfusion fluid readily inhibited pulsation of the toad's heart. Vitamin B_{12} or vitamin B_{12a}, added to the perfusion fluid, counteracted the inhibitory effect of cyanide and pulsation was restored.—A. M. Copping.

3078

BRIGNON, J. J. and WOLFF, R. Sur les corrélations entre la saponine et la vitamine B_{12} au cours de la croissance chez le poussin. [**Relations between saponin and vitamin B_{12} during growth of the chicken.**] *C.R. Soc. Biol.*, 1955, **149**, 1451–1452. [Lab. Chim. Biol., Fac. Méd., Nancy.]

The effect of saponin obtained from *Quillaja saponaria* was studied on chicks receiving vitamin B_{12} by mouth or by injection. The inhibition of growth by the saponin was apparent whether vitamin B_{12} was given or not, and irrespective of the way in which the vitamin was given. The observations of other workers on the growth-inhibiting effects of saponins from alfalfa meal are briefly discussed (*cf.* Title 3793, Abst. 5149, Vol. 18; 2942, 2943, Vol. 20).—A. M. Copping.

3079

RICHARDSON, L. R. and BROCK, R. **Studies of reproduction in rats using large doses of vitamin B_{12} and highly purified soybean proteins.** *J. Nutrition*, 1956, **58**, 135–145. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., College Station.]

Inclusion of vitamin B_{12} in a purified diet containing soya bean protein or casein improved the weaning weight and survival of young. No evidence was obtained to suggest that large amounts of vitamin B_{12} in the maternal diet were toxic to the young. Exhaustive extraction of soya bean protein with boiling water and with *iso*propanol did not affect reproduction or lactation in rats receiving it as sole protein in the diet. Five generations of females receiving diets with the highly purified proteins weaned more than 90 per cent. of their young. The problem whether unrecognised vitamins necessary for reproduction exist is discussed, and it is concluded that if such

substances were present they must have been very closely held by protein concentrates.

HALBROOK, E. R., BEECKLER, A. F. and SMITH, E. P. **Chicken feeding research. 1. The effect of various grain combinations in the diet on growth, egg production, feed efficiency, mortality, and market quality of chickens. 2. The effect of condensed fish solubles and vitamin B_{12}-antibiotic and vitamin B-complex supplements in the diet on growth, egg production, feed efficiency, mortality, hatchability of eggs, and market quality.** *Montana Agric. Exp. Stat. Bull.* No. 502, September 1954, pp. 17.

1. The studies reported extended over 7 years. A combination of wheat and oats was more satisfactory than a combination of wheat and barley, as source of carbohydrate in a basal diet, for growth and efficiency of feed utilisation up to 12 weeks of age. A mixture of wheat and barley was better for economical egg production and for efficiency of feed utilisation up to 24 weeks, and for the health of laying birds. It produced as high a grade of broilers as wheat and oats. A diet containing wheat and barley was superior to a mixture of maize, wheat, oats, bran and shorts as judged by liveweight and efficiency of feed utilisation up to 24 weeks of age. The wheat and barley diet was inferior to the more complex mixture for egg production and market quality of broilers.

2. When the diet contained 10 per cent. meat scraps, condensed fish solubles slightly increased growth and efficiency of feed utilisation. White Leghorn fowls seemed to respond better than New Hampshires to the addition of fish solubles. An antibiotic supplement containing vitamin B_{12} increased growth and efficiency of feed utilisation for egg production and reduced the mortality of young chicks. Supplements containing the vitamin B complex were of little value in the conditions of the experiment.—E. M. Cruickshank.

3081

HALBROOK, E. R., BEECKLER, A. F. and SMITH, E. P. **Turkey feeding research. 1. The effect of various grain combinations in the diet on growth, feed efficiency, mortality, and market quality of turkeys. 2. The effect of condensed fish solubles and vitamin B_{12}-antibiotic and vitamin B-complex supplements in the diet on growth, feed efficiency, mortality and market grade in Broad Breasted Bronze turkeys.** *Montana Agric. Exp. Stat. Bull.* No. 501, September 1954, pp. 14.

1. In experiments made over 3 years, barley was superior to oats as an addition to wheat in mash mixtures for turkeys, giving faster growth, more efficient utilisation of feed, lower mortality and better market quality of the carcase. A combination of wheat and oats or of wheat and barley was superior to a mixture of maize, wheat, oats, bran and shorts, in every comparison save that of market quality, which was slightly higher with the more complex mixture. It is concluded that barley can be used in place of oats and that complex grain mixtures are not necessary.

2. When condensed fish solubles or an antibiotic supplement containing vitamin B_{12} was added to diets containing 10 per cent. meat scraps, growth was faster, but efficiency of utilisation of feed and market quality of the carcase were not improved. No benefit was obtained by using a vitamin B complex supplement.

E. M. Cruickshank.

3082

MEADE, R. J. **The influence of protein content of the diet and of chlortetracycline and/or vitamin B_{12} supplementation upon performance of growing-fattening pigs.** *J. Animal Sci.*, 1956, **15,** 297–306. [Nebraska Agric. Exp. Stat., Lincoln.]

Sixty weanling pigs were divided at random into 12 groups of 5 and assigned to diets with 3 different amounts of protein and with 0, 2, 4 or 8 mg. chlortetracycline (aureomycin hydrochloride) per lb. diet. In a second test with 60 pigs the same amounts of protein were used with 5 mg. aureomycin, 5 μg. vitamin B_{12} or both. With protein percentages at successive stages of about 18–16–14, 16–14–12, and 14–12–10, there was no significant difference between the final weights after 96 days. Slight differences in growth of the pigs on the lowest intake of protein in the second experiment were possibly related to a change in the diet which gave a lower intake of tryptophan, methionine and lysine while the total amount of protein was unaltered. None of the supplements of aureomycin alone or with vitamin B_{12} affected growth with the amounts of protein used.

3083

JUCKER, H., WERREN, F. and SCHÜRCH, A. Versuche zur Feststellung der Wirkung von Vitamin-B_{12}-Gaben allein und mit Terramycin auf die Mastleistung verschiedenaltriger Mastschweine. [**Effect of giving vitamin B_{12} alone and with terramycin on the fattening of pigs at different ages.**] *Schweiz. Landwirtsch. Monatsh.*, 1955, **33,** No. 6, pp. 11. [Inst. Haustierernährung, Eidg. Tech. Hochsch., Zürich.]

Supplements of 25 mg. vitamin B_{12} alone or with 1·5 g. terramycin per ton feed were given to pigs of 22 or 38 kg. initial weight; other animals received the diet unsupplemented. With younger

animals both supplements increased gains in weight and improved feed utilisation and carcase condition; the combination of vitamin B_{12} and terramycin was more effective than vitamin B_{12} alone. With older animals there was no significant benefit.—A. M. Copping.

3084

CLIFFORD, R. J., HENDERSON, G. N. and WILKINS, J. H. **The effect of feeding penicillin and vitamin B_{12} to mature debilitated horses.** *Vet. Rec.*, 1956, **68**, 48–51.

Twelve horses in poor physical condition were divided into 2 groups comparable in general appearance, and were fed on a normal diet. One group was given a supplement equivalent to 1 g. procaine benzyl penicillin daily for 9 weeks without any appreciable change in condition. All the horses were then given a supplement equivalent to 15 μg. vitamin B_{12} daily for 8 weeks with a ration of increased energy value. There was considerable improvement whether penicillin had been given previously or not.—A. M. Copping.

3085

CABASSO, V. J., STEBBINS, M. R. and JOHNSON, D. W. **Effect of cortisone, ACTH, and vitamin B_{12} on distemper in ferrets.** *Vet. Med.*, 1956, **51**, 119–120; 122. [Viral and Rickettsial Sect., Res. Div., Amer. Cyanamid Company, Pearl River, N.Y.]

Intensive treatment with cortisone, adrenocorticotropic hormone and vitamin B_{12} did not prevent the death from distemper of infected ferrets. Combined treatment with cortisone and adrenocorticotropic hormone improved appetite and prolonged survival, but did not prevent the fatal effects of the infection.—A. M. Copping.

3086

BROWN, F. and CUTHBERTSON, W. F. J. **Vitamin B_{12} activity of *Chlorea vulgaris* Beij and *Anabaena cylindrica* Lemm.** *Nature*, 1956, **177**, 188. [Glaxo Laboratories, Ltd., Greenford, Middlesex.]

The vitamin B_{12} activity of two algae was investigated by the plate method with the *Bacterium coli* mutant, followed by chromatography, ionophoresis and bio-autography. Vitamin B_{12}, cyanocobalamin, represented 65 to 70 per cent. of the activity in *Anabaena cylindrica*, with pseudovitamin B_{12} and traces of factors A and B making up the remainder. The total activity was 0·63 μg. per g. dry weight. The cobalamin content of *Chlorella*, 6·3 μg. per 100 g. dryweight, was of the same order as that reported by Combs (Abst. 2502, Vol. 23). Both algae would contribute considerable amounts of cobalamin to the diet of man or animals.—A. M. Copping.

RABBI, A., VIVIANI, R. and MARCHETTI, M. Influenza della vitamina B_{12} sulla carenza dei fattori proteici animali (F.P.A.) della caseina nel ratto. [**Effect of vitamin B_{12} on the lack of the animal-protein factors (A.P.F.) of casein, in the rat.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 185–191. [Ist. Biochim., Univ. Bologna.] German, English and French summaries.

Rats were reared on a normal diet of mixed grains, vegetables and 5 per cent. crude casein, and on 2 diets with highly purified casein lacking animal-protein factor, with and without a supplement of vitamin B_{12}. Those given vitamin B_{12} showed normal fertility and reared their young, but the second generation failed to rear their young. Those with no vitamin B_{12} supplement were infertile in the first generation. The results suggest that the animal-protein factor in casein may not be identical with vitamin B_{12}.

VITAMIN C (ASCORBIC ACID)

3088

LAMPITT, L. H., BAKER, L. C. and WITTENBERG, E. **The photochemical oxidation of ascorbic acid in solutions containing oxalic acid. 2. Mechanism of the reaction.** *J. Sci. Food Agric.*, 1956, **7**, 120–124. [Lyons Labs., Cadby Hall, Kensington, London, W.14.]

For part 1 see Abst. 1798, Vol. 26.

When a solution at *p*H 1·7 containing oxalic acid, ascorbic acid and ferric ammonium sulphate was exposed to ultraviolet light in the absence of air it developed reducing power as measured by a dye solution. Ferric salts oxidise ascorbic acid in H_2SO_4 but not in oxalic acid solution. It is suggested that the oxidation of ascorbic acid depends upon OH and HO_2 radicals which are produced on

auto-oxidation of Fe^{2+} derived from the photochemical reduction of ferri-oxalate. The re-oxidation by air to Fe^{3+} of Fe^{2+} produced by irradiation of a solution of oxalic acid and ferric ammonium sulphate in an atmosphere of nitrogen depended on the ratio of iron to oxalate; when this exceeded 1/50, Fe^{2+} were produced in an atmosphere of air.—A. Hepburn.

3090

BURNS, J. J., DAYTON, P. G. and SCHULENBERG, S. **Further observations on the metabolism of L-ascorbic acid in guinea pigs.** *J. Biol. Chem.*, 1956, **218**, 15–21. [Res. Serv., Third (New York Univ.) Med. Div., Goldwater Mem. Hosp., New York.]

For previous work see Abst. 3543, Vol. 21.

From 3 guineapigs, 24 hr. after intraperitoneal injection of ascorbic acid labelled in the carboxyl atom or uniformly with ^{14}C, about 25 per cent. of the radio-activity was recovered as $^{14}CO_2$ and 9 per cent. in the urine, which showed that the entire carbon chain was extensively oxidised. The percentage of radio-activity recovered as ascorbic, diketogulonic and oxalic acids in the urine after 48 hr. was 34, 15 and 21·5 for L-ascorbic acid-1-^{14}C and 28, 20 and 9·7 for L-ascorbic acid-$^{14}C_6$; dehydroascorbic acid contributed less than 1 per cent. The half-life of ascorbic acid was calculated to be about 4 days in guineapigs; it is about 18 days in man (Title 5651, Vol. 25).—A. Hepburn.

3091

BHATTACHARYA, S. K., ROBSON, J. S. and STEWART, C. P. **The glutathione content of blood and tissues following alloxan and dehydroascorbic acid injections.** *Biochem. J.*, 1956, **62**, 12–21. [Dept. Clin. Chem., Univ. Edinburgh.]

Glutathione and total glutathione including oxidised glutathione were greatly decreased in blood of rabbits and rats after intravenous injection of amounts of alloxan sufficient to produce diabetes. In rats, glutathione decreased rapidly in the liver without the production of oxidised glutathione, but the amount was unchanged in the pancreas.

In rabbits, in contrast with rats, the blood sugar was not abnormally high after intravenous injection of dehydroascorbic acid, and the concentrations of glutathione, oxidised glutathione and total glutathione in the blood did not alter significantly. The concentrations of all three in the liver, pancreas and blood of the rat did not change except immediately after intravenous injection of dehydroascorbic acid when, in the liver, glutathione and total glutathione decreased sharply without the appearance of oxidised glutathione.

The results showed that the decrease of glutathione in the blood and tissues after administration of diabetogenic substances was not entirely, or even largely, due to oxidation of reduced to oxidised glutathione.—A. Hepburn.

UYAMA, Y., OGINO, S. and YAMADA, Y. **Biochemical studies on cataract. 2. Relationship between abnormal metabolism of tyrosine and cataract formation.** *Med. J. Osaka Univ.*,

1955, **6,** 519–528. [Dept. Ophthalmol., Med. Sch., Osaka Univ.]

Scorbutic guineapigs receiving tyrosine and sodium butyrate developed cataract and excreted benzoquinone acetic acid, the oxidised form of homogentisic acid, in the urine. When butyrate was omitted cataract did not develop and little benzoquinone acetic acid was excreted. Excretion of homogentisic acid and of *p*-hydroxyphenylpyruvic acid was similar in the 2 groups. The injection of benzoquinone acetic acid produced cataract in scorbutic guineapigs, which could be prevented by giving ascorbic acid or anthranilic acid, but not glutathione.—A. Hepburn.

MOURIQUAND, C. and EDEL, V. Évolution du fer intraérythroblastique non hémoglobinique au cours du scorbut aigu expérimental. [**Changes in the non-haemoglobin iron in the red cells during acute experimental scurvy.**] *C.R. Soc. Biol.*, 1955, **149,** 1576–1579. [Lab. Histol., Fac. Méd., Lyons.]

Of 21 guineapigs, 7 were fed on a stock diet and 14 on a scorbutogenic diet not lacking Fe. Smears of bone marrow were examined from time to time for sideroblasts (red cells containing cytoplasmic Fe granules) and Hb was estimated.

The non-deprived animals maintained the value for circulating Hb within the usual limits except for 2 low values. All but 3 of the deprived showed a considerable fall in Hb. In the non-deprived the percentage of sideroblasts was normal, from 40 to 90, but most of the deprived animals showed a sharp fall after the 19th day, and one animal after the 14th. The size of the Fe granules diminished so that they became difficult to find. Three animals with clinical scurvy showed no decrease in sideroblasts. There was no close relation between the behaviour of the Hb and of the sideroblasts.

After from 21 to 25 days, 4 of the scorbutic guineapigs received a single injection of ascorbic acid; the rest died. In the treated guineapigs the sideroblast counts were normal or almost normal after from 2 to 14 days.—D. Duncan.

MÜLLER, W. and NOVER, A. Kernveränderung in den Ganglienzellen der Netzhaut bei experimentellen Vitamin-C-Mangel. [**Alterations of the nuclei in the ganglion cells of the retina during experimental vitamin C deficiency.**] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1955, **7,** 277–280. [Max-Planck-Inst. Hirnforsch., Abt. Tumorforsch. Exp. Pathol., Univ. Cologne.] English and French summaries.

Sections of retinal tissue from pairs of guineapigs of the same weight, one normal and one scorbutic, were stained with haematoxylin and eosin and the size of the nuclei was measured in two dimensions. No difference in size of nuclei or in staining could be detected in ganglion cells from the retina of scorbutic and normal animals.—A. M. Copping.

3098

SRIRAMACHARI, S., PIRANI, C. L. and HAYMAKER, W. **The effect of traumatic injury on the brain of vitamin-C-deficient guinea-pigs.** *Amer. J. Pathol.*, 1956, **32,** 131–139. [Armed Forces Inst. Pathol., Washington 25, D.C.]

Of 22 guineapigs weighing about 250 g. and fed on a scorbutogenic diet, 9 received in addition 0·2 mg. vitamin C daily, and 13 had 2 mg. Animals were killed after 3, 6, 8, 12 and 16 weeks, and the brain was examined. There were no petechiae visible, and no changes in the parenchyma of the brain.

In a second experiment with 2 groups of 8 or 10 guineapigs fed on the same diet with one of the same 2 supplements, a punctured wound was made in the brain 10 days after the diets were started. Animals were killed 3, 8, 10, 15 or 22 days later, and the site of injury was examined histologically. In the scorbutic animals there was lack of healing, particularly at the mouth of the wound in the region of the meninges. The failure to heal was not in essence different from that in other organs of the body of scorbutic animals, where lack of differentiation of mesenchymal elements is characteristic. In the reaction of the mesoglia, scorbutic animals showed no abnormality.

3099

KUROKAWA, T. **The influence of vitamin C deficiency on the heteroplastic bone formation induced by transplantation of urinary bladder epithelium.** *Keio J. Med.*, 1955, **4,** 47–59. [Dept. Pathol., Sch. Med., Keio Univ.]

In 60 guineapigs weighing from 200 to 300 g. small pieces of mucosa from the bladder wall were implanted under the fascia of the abdominal muscle. After the operation the animals were given a scorbutogenic diet, and half of them had some green food or about 10 mg. vitamin C daily. They were all killed after 21 days, when signs of scurvy were apparent in the deprived animals. The implants had formed nodular indurations which were excised and examined histologically. Healing of the wound was much delayed in the deprived group. Bone formation in the cysts formed was frequent in the non-deprived animals, but very rare in the deprived. In the deprived there was a type of hyalinised lesion with proliferation of elastic fibres that did not occur in the non-deprived. No inhibition of collagen formation was observed in the deprived animals.

BOLKER, H. I., FISHMAN, S., HEARD, R. D. H., O'DONNELL, V. J., WEBB, J. L. and WILLIS, G. C. **The incorporation of acetate-1-C^{14} into cholesterol and fatty acids by surviving tissues of normal and scorbutic guinea pigs.** *J. Exp. Med.*, 1956, **103**, 199–205. [Dept. Biochem., McGill Univ., Montreal.]

Incorporation of ^{14}C into cholesterol and fatty acids, when acetate-1-^{14}C was incubated for 3 hr. with tissue from the liver, adrenal glands or aorta of guineapigs fed on a scorbutogenic diet, was not different from that when the diet contained ascorbic acid. Much more was incorporated into the liver than into the adrenal glands or aorta. Cholesterol and hexosamine were above normal in the serum of scorbutic guineapigs.

DESMARAIS, A. and MCGRAW, J. Y. Influence des vitamines A et D sur la croissance et la résistance capillaire du cobaye carencé ou non en acide ascorbique. [**Effect of vitamins A and D on growth and capillary resistance of guineapigs deprived or not deprived of ascorbic acid.**] *C.R. Soc. Biol.*, 1955, **149**, 1718–1722. [Dept. Exp. Physiol., Laval Univ., Quebec.]

Male albino guineapigs weighing about 500 g. were given a scorbutogenic diet to appetite, and were divided into 4 groups of 15 animals each. Group 1 had no supplement; groups 2 and 4 had daily supplements of 5 mg. ascorbic acid; groups 3 and 4 had daily supplements of 0·075 mg. calciferol during the first 16 days of the experiment and then of 0·075 mg. β-carotene instead. All the supplements were given by mouth. Bodyweight was recorded throughout the experiment and, at intervals, capillary resistance was measured by a negative-pressure method.

After 56 days the animals in group 2 weighed on the average 80 g. more than those in group 1. The weight gain of both groups given calciferol was retarded initially; when carotene was substituted they grew more rapidly and by the 56th day their weights were intermediate between those of the other two groups.

The capillary resistance of the guineapigs in group 1 fell progressively to a very low level on the 46th day, and the same value was maintained during the remainder of the experiment. The capillary resistance of the animals in group 2 rose at first but fell again to normal by about the 26th day and continued to fall during the following 20 days. The resistance of both groups given calciferol fell during the first 16 days. When carotene was substituted resistance was stabilised in group 3 and restored to normal in group 4.

PORTER, J. C. and JONES, J. C. **Effect of plasma from hypophyseal-portal vessel blood on adrenal ascorbic acid.** *Endocrinology*, 1956, **58**, 62–67. [Dept. Physiol., Southwestern Med. Sch. Univ. Texas, Dallas.]

Blood was taken from the hypothalamico-hypophyseal portal vessel and from the common carotid artery of 12 dogs. The effect of the 2 lots of plasma on the content of ascorbic acid in the adrenal glands was tested on adult rats which had had the pituitary gland removed, and on intact rats which had received intraperitoneal injections of hydrocortisone acetate to inhibit the release of adrenocorticotropic hormone from the pituitary gland. That effect of hydrocortisone was experimentally confirmed. After the preparatory treatment and before injection of the test plasma, the left adrenal gland was removed; 90 min. after injection of the test plasma the right adrenal gland was removed, and ascorbic acid was estimated in both of them. The ascorbic acid content was significantly less after injection with blood plasma from the hypophyseal portal vessel than with plasma from the carotid artery in the rats injected with hydrocortisone, but not in those from which the pituitary gland had been removed.

It is suggested that blood from the hypophyseal portal vessel contains one or more substances which accelerate the release of adrenocorticotropic hormone from the anterior lobe of the pituitary gland.—E. M. Hume.

3103

HOLZBAUER, M. and WALTER, K. **Inactivation of the adrenal ascorbic acid-depleting activity of pituitary extracts by ascorbic acid.** *Nature*, 1956, **177**, 379–380. [Dept. Pharmacol., Univ. Edinburgh.]

On injection into hypophysectomised rats, a Ringer solution which contained ascorbic acid and adrenocorticotropic hormone (ACTH) and had been kept at room temperature for from 18 to 24 hr. had only 1·9 per cent. of the power to deplete adrenal ascorbic acid possessed by a similar solution without ascorbic acid. Simultaneous injections of ascorbic acid kept in Ringer solution only for the same time and of ACTH did not give the effect. Previous work showed that in the same way ascorbic acid inhibited the ability of ACTH to expand the chromatophores in isolated frog skin.—A. Hepburn.

3104

DESMARAIS, A. and GAGNON, P. M. Influence de l'exposition au froid sur l'activité thyroïdienne et sur le poids et la teneur en acide ascorbique des surrénales chez le cobaye carencé ou non en acide ascorbique. [**Effect of exposure to**

cold on the thyroid activity and on the weight and ascorbic acid content of the adrenal glands in the guineapig deprived or not deprived of ascorbic acid.] *C.R. Soc. Biol.*, 1955, **149,** 1714–1718. [Dept. Exp. Physiol., Laval Univ., Quebec.]

Male guineapigs were fed on a diet deficient in ascorbic acid for 21 days, by which time signs of deficiency were clearly evident. Two other groups of guineapigs received 5 or 150 mg. ascorbic acid daily. From the 3 groups, 9, 8 and 6 animals were kept at room temperature and 14, 6 and 6 were kept at 10° ± 1° C. for 6 days before being killed.

The guineapigs receiving both doses of ascorbic acid grew normally, though their weight fell temporarily on exposure to cold. The growth of the guineapigs not receiving ascorbic acid decreased from the 18th day and was little affected by cold. The weight of the adrenal glands increased only in the scorbutic guineapigs exposed to cold; the hypertrophy was prevented by ascorbic acid (see Abst. 2125, Vol. 19). The amount of ascorbic acid in the adrenal glands depended directly on the amount given and was greatest in the animals exposed to cold. Among the latter the degree of retention was highest in the scorbutic guineapigs. Thyroid activity, as measured by the height of the vesicle epithelium, was increased only in the scorbutic guineapigs exposed to cold.

Berzin, V. K. Vliyanie nedostatka askorbinovoi kisloty na reaktivnost' organizma v opytakh proverki toksigennosti difteriinykh kul'tur. [**Effect of ascorbic acid deficiency on the capacity of the system to react in tests of the toxicity of diphtheria cultures.**] Gipovitaminoz C kak faktor, snizhayushchii priobretennyi immunitet k difterii ili prepyatstvuyushchii ego razvitiyu. [**Vitamin C deficiency as a factor in lowering acquired diphtheria immunity or inhibiting its development.**] *Zh. Mikrobiol. Epidemiol. Immunobiol.*, 1955, No. 7, 71–74; No. 9, 18–22.

(*a*) Experiments on guineapigs showed that partial deprivation of ascorbic acid inhibited the development of immunity to diphtheria after a course of active immunisation. The inhibition was affected by the size of the infecting dose and the duration of the state of partial deficiency. It is suggested that ascorbic acid might form a useful adjunct in the active immunisation of children against diphtheria.

(*b*) As a result of observations showing a fall in resistance to infection during the winter and early spring, correlated with a low ascorbic acid content of the diet, experiments were performed to test the resistance to injection with strains of *Corynebacterium diphtheriae* of 3 groups of guineapigs, normal animals, animals on a low intake of ascorbic acid and frankly scorbutic animals.

Resistance was reduced in proportion to the degree of deficiency. All frankly scorbutic animals died within 2 or 3 days and showed little sign of inflammatory reaction, and from many of them bacteria were recovered. The ascorbic acid content of the adrenal glands was greatly decreased. About 25 per cent. of the partly deprived animals died in from 5 to 10 days. They exhibited necrosis at the site of injection and inflammatory exudates in the body cavities.—D. W. Taylor.

3106

Perez y Perez, F. Contribución al estudio de los factores enzimáticos de la esterilidad. Hialuronidasa y vitamina C. [**Enzymes in relation to sterility. Hyaluronidase and vitamin C.**] *An. Inst. Invest. Vet., Madrid*, 1954, **6,** 145–161. [Cat. Cirug. Obstet., Fac. Vet., León.] English and German summaries.

Bull semen diluted with egg yolk and citrate buffer showed more abnormal sperms and a shorter time of survival when hyaluronidase was added. Addition of vitamin C did not prolong survival, but reduced the number of abnormal forms. When both substances were added, vitamin C prevented the adverse effect of hyaluronidase. High concentrations of vitamin C were harmful.—D. Duncan.

3107

Koser, S. A. and Thomas, J. L. **Effect of ascorbic acid on cysteine requirement of lactobacilli.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 454–458. [Walter G. Zoller Mem. Dent. Clin., Univ. Chicago, Ill.]

Six of 36 strains of oral lactobacilli tested could grow without cysteine. Ascorbic acid and other reducing substances could replace cysteine for 5 other strains which needed cysteine, of which one was *L. casei* and the others were strains of the heterofermentative species *L. fermenti*. Ascorbic acid usually accelerated the growth of lactobacilli which required cysteine but did not affect the final amount of growth.—A. Hepburn.

3108

Anagama, Y. Studien über Vitamin C in Milch und Milchprodukten. [**Vitamin C in milk and milk products.**] *J. Fac. Fish. Animal Husb. Hiroshima Univ.*, 1955, **1,** 49–94. [Fukuyama, Japan.]

After an extensive review (137 references) of the literature, except that for the war years, from which values for the vitamin C content of milk are quoted, the results of experiments begun in 1938 and pursued at different times between then and

1952 are reported in tables. Vitamin C was estimated throughout by the 2 : 6-dichlorophenol-indophenol method of Radeff (Abst. 4816, Vol. 7).

The monthly mean vitamin C content, in mg. per 100 ml., of the mixed morning milks of 29 Holstein and 9 Guernsey cows in June-July 1938 was 1·64 and 2·34, respectively. It varied from day to day and from cow to cow. Of 2 Holstein × Jersey cows sired by the same bull, one gave milk resembling that of Holsteins in vitamin C content, the other milk resembling that of Jerseys.

The vitamin C content of the colostrum of 14 cows of different breeds was high at first but fell rapidly to a minimum within a few days and then rose a little ; it was not the same in different lactations of the same cow.

In 12 cows of different breeds, the milk was generally richer in vitamin C in the later stages of lactation, and between October and January.

Substitution of 25 kg. fresh grass for 8 kg. rice straw in the diet of 3 cows raised the vitamin C content of the milk, but only slightly.

Differences between different quarters of the udder and different portions of the same milking, and after different intervals between milkings, were slight.

In laboratory-scale experiments on the effects of pasteurisation and storage, vitamin C loss was greatest after heating for 30 min. at 95° C. and cooling rapidly, and least after bringing to the boil and cooling rapidly ; boiled milk, unlike fresh milk, did not lose vitamin C when kept cold in the dark for 30 hr.

Vitamin C was rapidly destroyed by exposure of milk to light, especially direct sunlight ; red cellophane gave better protection than violet, yellow or green. It is recommended that " vitamin C milk " should be produced by adding ascorbic acid to resemble good human milk in vitamin C content (about 4 mg. per cent. in Japan, according to values quoted from their literature) ; it should be sold in red bottles.

Fe had little effect on vitamin C content, but the effect of Cu was serious.

Separated milk contained as much vitamin C as whole milk. Japanese spray-dried milk varied greatly with brand and age, from 0·6 to 9·4 mg. per 100 g. powder. Packing in nitrogen was not always advantageous, but blowing nitrogen through the milk during spraying assisted retention of added ascorbic acid. In winter in Hokkaido an opened tin retained its vitamin C for about a fortnight. Sweetened condensed milk contained from 2·24 to 3·28 mg. vitamin C per 100 g. undiluted, from a third to a half of that of the original milk ; vitamin C was lost on keeping, but different brands varied less than brands of dried milk. Unsweetened condensed milk had from 0·48 to 1·90 mg. vitamin C per 100 g. undiluted, from 15 to 60 per cent. of that of the original milk, and the amount did not vary with the age of the sample.

NOBLE, I. and GORDON, J. **Ascorbic acid and color retention in green beans cooked by different methods.** *J. Amer. Dietetic Assoc.*, 1956, **32**, 119–122. [Sch. Home Econ., Univ. Minnesota, St. Paul.]

Ten varieties of green bean were boiled in an open pan with sufficient water or cooked in a tightly closed pan with just enough water to prevent scorching or cooked in a pressure cooker at 15 lb. pressure or steamed.

The ascorbic acid content of the raw beans ranged from 12·0 to 22·0 mg. per 100 g. in the different varieties, average 16·5 mg. Replicate analyses showed considerable variation in the retention of ascorbic acid after cooking. The average percentage retention of ascorbic acid derived from 48 samples was, in the order of the cooking methods given above, 60, 71, 76 and 76 ; the first result was significantly different from the others. Beans cooked in the pressure cooker were greener than those cooked in the open pan ; both had almost the colour of the raw vegetable. Beans cooked by the other methods were yellow.

BERGAMINI, A., BENDANDI, A., CHIEREGO, G. and MAGGI, G. Sul quadro enzimatico della steatosi epatica da dieta iperlipidica-ipoprotidica: variazioni dopo trattamento lipotropo. [**The enzyme pattern in fatty liver caused by a diet high in fat and low in protein: changes after treatment with lipotropic substances.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31**, 521–523. [Ist. Clin. Med., Univ. Modena.]

Forty-five male rats weighing from 130 to 150 g. were maintained for 40 days on a diet high in fat and low in protein. Different substances reputed to be lipotropic were given and, in the liver, total fats, tributyrin esterase, alkaline β-glycerophosphatase and β-glucuronidase were estimated. The lipotropic substances were choline chloride 25 mg., methionine 100 mg., or inositol 60 mg., given daily by intramuscular injection, or the lipotropic factor of the pancreas given as 5 per cent. of the diet. With the diet alone, the fat content of the liver was nearly doubled. Any of the 4 lipotropic substances kept it normal.

Tributyrin esterase was slightly reduced in the liver with the diet alone, and choline and methionine had no effect on it; inositol restored the amount to normal, and the lipotropic factor of the pancreas raised it above normal. The diet alone increased β-glycerophosphatase, and all the four lipotropic substances decreased it. The amount of β-glucuronidase was not affected by the diet or by the lipotropic substances.—E. M. Hume.

MCGEACHIN, R. L. **Effect of amino acids and proteins on amylase activities of body fluids.** *Biochim. biophys. Acta*, 1956, **19**, 391. [Dept. Biochem., Univ. Louisville, Ky.]

The amylase activity of diluted saliva was increased by about 20 per cent. when 50 mg. glycine or 7 mg. bovine plasma was added. Addition of both did not further increase the activity. Glycine increased activity by about 10 per cent. in the presence of as much as 0·1 mg. plasma albumin, but had no effect on the amylase activity of fresh or dialysed urine containing less than 0·1 mg. protein per ml. It was assumed that salivary amylase was different from amylase in urine or that urine contained a non-protein, non-dialysable activator of amylase. Serum amylase activity was not significantly increased by the addition of 9 amino acids in separate trials. A mixture of saliva and serum had more than the calculated amount of amylase activity, but the addition of glycine produced no further increase.—A. Hepburn.

3114

DE MARCO, B. and CUSMANO, F. La determinazione dell'anidrasi carbonica nei lattanti eutrofici, prematuri e distrofici. [**Estimation of carbonic anhydrase in well nourished, premature and dystrophic infants.**] *Lattante*, 1955, **26**, 388–400. [Ist. Provinciale Protezione Assistenza Infanzia, Genoa.] English summary.

Carbonic anhydrase was estimated by the colorimetric method of Philpot and Philpot (*Biochem. J.*, 1936, **30**, 2191) in the blood of 6 normal men, 10 normal women, 10 normal infants and 8 premature infants. Values for carbonic anhydrase were a good deal higher for men than for women. For normal infants they were about the same as for women; for premature infants they were considerably lower and for dystrophic infants a little lower still. It is thought that concentration of carbonic anhydrase in the blood could be used as a criterion of nutritional state and of maturity in the infant.—E. M. Hume.

3115

SHIRLEY, R. L., EASLEY, J. F., HAINES, C. E. WARNICK, A. C., WALLACE, H. D. and DAVIS, G. K. **Influence of dietary energy level on succinoxidase and lactic dehydrogenase of the heart of pregnant swine.** *J. Agric. Food Chem.*, 1956, **4**, 68–70. [Dept. Animal Husb. Nutrit., Univ. Florida, Gainesville.]

The 31 gilts, weighing on the average 114 lb., were in 2 groups running on pasture. Those of one group were fed to appetite, the others had half the amount of another ration, which supplied about the same quantities of protein, vitamins and minerals but only half the energy intake. All the gilts were mated at the second oestrus, about 106 days after they were put on the rations; half of each group were killed 3 days after mating and the rest 22 days later. Succinoxidase and lactic dehydrogenase were estimated in heart muscle.

The succinoxidase activity of left ventricle was significantly greater at both stages of gestation in the fully fed than in the restricted pigs. There was no significant effect of stage of gestation. In lactic dehydrogenase there was no significant difference.—D. Duncan.

Savary, P. and Desnuelle, P. Sur quelques éléments de spécificité pendant l'hydrolyse enzymatique des triglycérides. [**Specificity in enzymic hydrolysis of triglycerides.**] *Arch. Sci. biol., Bologna*, 1955, **39**, 689–704. [Lab. Chim. Biol., Fac. Sci., Marseilles.]

During hydrolysis of 3 pure triglycerides, 2-oleodipalmitin, 1-oleodipalmitin and 1-palmitodiolein, and of several mixtures of natural or synthetic glycerides, it was found that pancreatic lipase attacked preferentially the external chains in positions 1 and 3, but chains in position 2 were eventually attacked. The hydrolytic reactions thus gave triglycerides → 1 : 2-diglycerides → 2-monoglycerides. The length and unsaturation of the chains did not affect the rate of breakdown.

Tascher, R. and Müller, N. Zur Frage rassischer und geographischer Einflüsse auf die Serumphosphataseaktivität im Entwicklungsalter. [**Racial and geographical influences on serum phosphatase activity during development.**] *Ztschr. Kinderheilk.*, 1956, **77**, 497–503. [Med. Klin., Univ. Homburg, Saar.]

The values found by the authors (in the press [journal not indicated]) by the method of King and Armstrong for alkaline phosphatase in the serum of normal children from 1 to 16 years of age in their own locality are compared with those found by different methods by 11 other authors from several places in Europe, Canada, United States and Israel. It was concluded that race and geographical region had no effect except in so far as they might influence development. The authors' results show a steady fall from about 20 King Armstrong units to about 10 at age 7 in both sexes, and then a rise in girls to almost 16 at age 12, followed by a second fall; in boys the rise was about 2 years later and there was no second fall.

It is stated that acid phosphatase in serum did not vary with age, sex, race or locality.

Szczygłowa, M. and Secomska, B. Przydatność oznaczania fosfatazy alkalicznej w surowicy krwi do masowych badań nad stanem odżywienia oraz do celów diagnostycznych. [**The use of alkaline phosphatase estimation in blood serum for mass examination of nutritional status and for diagnostic purposes.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6**, 379–387. Russian and English summaries.

The method was that of Bessey *et al.* (Abst. 2569, Vol. 16; 1589, Vol. 22). Blood samples were taken from the pulp of the finger or heel. The results obtained by Bessey's method are in *p*-nitrophenol units; the factor 1·79 converts them to Bodansky units.

In 20 adult subjects the levels of alkaline phosphatase agreed well with those in the literature, except that in 4 with diseases of the liver and in a pregnant woman the estimated levels were higher.

Values for venous and capillary blood, in Bodansky units, were in one subject 2·8 and 2·5, in another 3·6 and 3·9, respectively.

To test the factor 1·79 used to convert *p*-nitrophenol units to Bodansky units, estimations were made by both methods. The tabulated results show good agreement except in 2 subjects with jaundice, which made colorimetric estimation difficult.—W. Z. Billewicz.

Le Magnen, J. La satiété induite par les stimuli sucrés chez le rat blanc. [**Satiety induced by sugars as stimuli in the white rat.**] *C.R. Soc. Biol.*, 1955, **149**, 1339–1342.

Fifteen adult male rats were given 2 meals daily of an adequate basal diet, each lasting 90 min. After 10 days test substances were given either orally or by stomach tube 15 min. before the morning meal and their effect on the amount of food consumed was noted.

After the ingestion of 5 ml. of a 10 per cent. solution of sucrose the intake of solid food was reduced by about 50 per cent. The administration of this same solution by stomach tube was without effect on food intake, as was the administration by stomach tube of water. In one experiment the ingestion of 5 ml. of a 0·25 per cent. solution of saccharin indicated an effect similar to that of sucrose, but in two subsequent experiments the saccharin was without effect. The administration by stomach tube of this solution of saccharin was also without effect. The ingestion of 5 ml. of a 2 per cent. NaCl solution, of 0·01 *N* acetic acid or of 0·005 per cent. quinine sulphate was without effect on subsequent food intake.—G. F. Garton.

3125

GEIGER, E. and PINSKY, J. J. **Effect of changes in environmental temperature on stomach emptying in rats.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 107–110. [Dept. Pharmacol., Med. Sch., Univ. S. California, Los Angeles.]

The nitrogen left in the stomach 2 hr. after a standard protein meal was taken as a measure of the emptying rate of the stomach. At room temperature over 80 per cent. of the N disappeared from the stomach in 2 hr. Removing the rats to temperatures of 3° or 37° C. immediately after they had finished the test meal delayed emptying of the stomach. Five days of acclimatisation to these temperatures was sufficient to allow the emptying time to return to normal. Decreased gastric motility as a result of increased production of adrenaline is suggested as the cause of the delay in emptying after sudden changes of temperature.

3126

REYNELL, P. C. and SPRAY, G. H. **The simultaneous measurement of absorption and transit in the gastro-intestinal tract of the rat.** *J. Physiol.*, 1956, **131,** 452–462. [Nuffield Dept. Clin. Med., Univ. Oxford.]

Phenol red is not absorbed to any extent, but in rats only 90 per cent. of the phenol red given in a test meal can be recovered from the stomach when the animal is killed immediately after its ingestion. By subdividing the intestine and calculating the percentage of the marker present in a given segment, an estimate of the rate of movement along the intestine as well as of gastric emptying time can be made. Considerable variation between animals was found in gastric emptying time, and in the intestine propulsive movements became slower as the caecum was approached.

Glucose absorption starts in the stomach, and the 400 mg. in the test meals was absorbed by the time the meal was halfway through the small intestine. Iodide, included for comparison, was absorbed more slowly, not at all from the stomach.—A. T. Phillipson.

Klin., Univ. Erlangen.]

For part 7 see Abst. 311, Vol. 26.

The rate of passage of a barium meal given by stomach tube was studied in rats fasted for 48 hr. After a control study 25 rats received 25 mg. terramycin and another 25 had 25 mg. aureomycin daily in aqueous solution by stomach tube. In 10 rats of each group a barium meal was given 2 hr. after the first dose of antibiotic. Other tests were made after the antibiotics had been given for 14 and 26 days. The effect of 5 μg. vitamin B_{12} injected intraperitoneally daily for 3 days was studied also.

After a single dose of antibiotic, and especially after aureomycin, the rate of passage of the barium meal was increased, especially in the cranial part of the digestive tract. After 14 days the rate of passage was almost normal, and after 26 days it was significantly slower than normal, especially the emptying of the stomach. Again aureomycin had more effect than terramycin. Three days of treatment with vitamin B_{12} restored the rate of passage to normal.

Isolated loops of small intestine from rats showed a fall in tonus and increased activity in the presence of aureomycin solution. Vitamin B_{12} reduced activity without affecting tonus.

Dünndarmbeschaffenheit bei Schweinen. [**Effect of aureomycin on the condition of the small intestine in pigs.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 364–374. [Tierzucht-Inst., Univ. Kiel.] English summary.

Studies were made of the small intestine of 49 pigs which had been fattened from 20 kg. to different weights on cereals with or without aureomycin, 10, 20 or 50 mg. per kg. feed. For measurement of length the intestine, cut into 3, was suspended under a pull of 130 g. in physiological saline. Volume was measured at fluid pressure of 20 cm. The intestine was then dried, weighed and analysed.

No connection was found between slaughter weight and length or volume of intestine. Aureomycin did not significantly affect length or dry weight of intestine, and there was no difference in chemical composition ; the volume of the intestine was less, in some groups significantly so.

ISHIHARA, Y. [**Experimental studies on the digestibility of milk proteins. 1. On the digestibility of human and cow's milk proteins by proteolytic enzymes *in vitro*. 2. On the digestibility of human and cow's milk proteins by human digestive juices. 3. Paper chromatography of amino acid liberated from human and cow's milk proteins by proteolytic enzymes or human digestive juice.**] *Shikoku Acta Med.*, 1955, **7,** No. 5, 41–45 ; 46–49 ; 50–56. [Dept. Paediat., Sch. Med., Tokushima Univ. In Japanese : English summary.

1. Samples of human and cow's milk were analysed for amino N after enzymic digestion for ½, 1, 2 or 3 hr. ; the results are tabulated in English as the amount found and as a percentage of total N. With pepsin the amount was small for both milks and the percentage slightly greater for human than for cow's milk. With trypsin the amounts were larger than with pepsin and the percentage was slightly greater for cow's than for human milk. With trypsin after pepsin the amounts were still greater and the percentage for human was greater than for cow's milk.

2. In similar studies with human gastric and duodenal juices amino N liberated from human milk was greater than from cow's milk both in amount and as a percentage of total N.

3. No amino acid was found after digestion of either milk with pepsin or gastric juice. With trypsin or duodenal juice the amounts of amino acids rose with time of digestion ; with duodenal juice arginine and lysine appeared earlier in human than in cow's milk. With trypsin after pepsin or with duodenal after gastric juice amino acids appeared earlier than with trypsin or duodenal juice alone.—D. Harvey.

DE LANGEN, C. D. Die Vasomotilität bei Sprue und anderen Resorptionsstörungen. [**Vasomotor action in sprue and other disorders of absorption.**] *Gastroenterologia*, 1956, **85,** 1–10. [Utrecht.] English and French summaries.

Almost without exception patients with sprue, tropical and non-tropical, and steatorrhoea have low blood pressure. From repeated studies of such patients the question arose : is the disorder of absorption or that of vasomotor control the primary ? Detailed studies of 3 patients with steatorrhoea showed low blood pressure ; low B.M.R. that did not rise when thyroid was given ; abnormal histamine and cantharidin reactions in the skin ; low venous and capillary pressure ; liability to faint ; low intramuscular pressure ; hydergen (from ergot) increased excretion of fat, presumably by reducing absorption ; all had periodic meteorism and flat blood sugar and blood fat curves in response to tests. Treatment partly reversed these deviations from normal, but blood pressure did not rise to normal. It is suggested that the disturbance of capillary circulation may be primary or the disorders of circulation and absorption may be inseparably associated.

GRUSKAY, F. L. and COOKE, R. E. **The gastrointestinal absorption of unaltered protein in normal infants and in infants recovering from diarrhoea.** *Pediatrics*, 1955, **16,** 763–767. [Dept. Paediat., Sch. Med., Yale Univ., New Haven, Conn.] Spanish and Interlingua summaries.

In 21 infants recovering from diarrhoea and in 19 normal infants levels of egg albumin in serum after ingestion of the crystalline protein were estimated by an immunochemical method. Concentrations of egg albumin were significantly higher in infants with diarrhoea than in normal infants, and estimation of haematocrit showed that the difference was not one of haemoconcentration.

BLOMSTRAND, R. and LINDQUIST, B. **The intestinal absorption of carbon-labelled oleic acid in the normal infant and in congenital bile duct atresia.** *Helv. paediat. Acta*, 1955, **10**, 627–639. [Dept. Physiol. Chem., Univ. Lund.] German, French and Italian summaries.

A mixture which consisted mainly of di- and triglycerides was prepared from commercial monopalmitin with the acid chloride of oleic acid-1-^{13}C. The labelled mixture was dissolved in olive oil and administered to a normal 5-month-old boy, a normal 9-month-old girl and a 12-month-old girl with congenital atresia of the bile ducts. The amount of labelled fatty acid absorbed was calculated from the difference between the amount of ^{13}C administered and that recovered from the faecal lipids, permitting a distinction between dietary and endogenous faecal fat.

On the average 85 per cent. of the oleic acid administered to the normal infants was absorbed, and 42 per cent. by the infant with biliary atresia. It was demonstrated that unabsorbed oleic acid was excreted as such, though a small proportion was hydrogenated, presumably by bacterial action.

BLOMSTRAND, R., LINDQUIST, B. and PÄÄBO, K. **The intestinal absorption of carbon-labelled oleic and palmitic acid in the normal infant and in cystic fibrosis of the pancreas.** *Helv. paediat. Acta*, 1955, **10**, 640–648. [Dept. Physiol. Chem., Univ. Lund.] German, French and Italian summaries.

Intestinal fat absorption was studied in a normal 8-month-old boy and in one aged 17 months with cystic fibrosis of the pancreas, one of the manifestations of which is steatorrhoea. In experiments similar to those described in the previous abstract glycerides containing ^{13}C-labelled oleic and palmitic acids were given.

The normal infant absorbed 93 per cent. of the labelled acids and the child with cystic fibrosis of the pancreas only 26 per cent. It is concluded that the pathological steatorrhoea is due to unabsorbed dietary fatty acids, though the non-dietary component of the faecal fatty acids was about twice that found in the normal child. In both infants a small proportion of the unabsorbed oleic acid was hydrogenated.—G. A. Garton.

SMITH, A. H., KLEIBER, M., BLACK, A. L. and LUICK, J. R. **Transfer of phosphate in the digestive tract. 1. Swine.**

SMITH, A. H., KLEIBER, M., BLACK, A. L. and BAXTER, C. F. **2. Sheep.**

SMITH, A. H., KLEIBER, M., BLACK, A. L. and LOFGREEN, G. P. **3. Dairy cattle.** *J. Nutrition*, 1955, **57**, 497–506; 507–527; 1956, **58**, 95–111. [Dept. Animal Husb., Univ. California, Davis.]

1. ^{32}P was injected into the bloodstream of pigs 2, 4 and 8 months old. Animals in each age group were slaughtered at different times up to 48 hr. after injection. The radio-activity of the contents of the digestive tract was estimated and compared with that of the tissues of the segment from which they were taken. Secretion of inorganic P occurs in the small intestine and re-absorption in the large intestine.

The rate of decrease of activity in the plasma declined with age and so did the secretion of endogenous P into the small intestine.

2. ^{32}P was injected intravenously into lambs 1, 4 and 10 months old. The quantity found in the alimentary contents of the young lambs was small compared with that in older animals. The concentration in the contents was greatest in the rumen, omasum and abomasum, and it is calculated that the quantity entering the rumen across the rumen epithelium is greater than the quantity entering in the saliva. The omasal wall is considered also to secrete P into the contents. Very little enters the intestines.—A. T. Phillipson.

3. ^{32}P was injected into the jugular vein of calves, which received 2·6 to 9·9 mC. each, and cows, 4·7 to 17·1 mC., and they were killed from 0·5 to 72 hr. after injection. Samples of contents and tissues of the digestive tract of each animal were collected for estimation of total and radioactive P.

There was a large secretion of endogenous P in the cow; most of this was found in the rumen, where the apparent daily rate of secretion was estimated at about 66 g., but it was also estimated that almost the whole of this amount reached the rumen from the salivary glands. Thus secretion by rumen epithelium was very small in the cow, much less relative to liveweight than in the sheep (see above). The total secretion into the stomach of the cow was considerably greater than in the sheep, per unit of liveweight.

A small amount of P was secreted by the wall of the small intestine in the cow; in the calf most endogenous P was secreted by this tissue. Exchange of P between plasma and intestinal tissue was generally less in the cow than in the sheep.

STEWART, J. and MOODIE, E. W. **The absorption of magnesium from the alimentary tract of sheep.** *J. Comp. Pathol.*, 1956, **66**, 10–21. [Moredun Inst., Gilmerton, Edinburgh.]

Two hours after receiving magnesium sulphate by mouth sheep were anaesthetised and veins draining different parts of the digestive tract were exposed. The absorption of Mg was estimated by

comparing the concentration in blood draining the digestive tract with the concentration in blood from the carotid artery.

There was evidence of slight absorption of Mg from the rumen, abomasum, duodenum, and small intestine, but none from the caecum or colon.

When $MgSO_4$ was introduced through cannulae directly into different parts of the digestive tract more definite evidence of absorption was obtained. The principal sites were apparently the duodenum and small intestine, but absorption took place also from the rumen, abomasum and caecum. Mg given as nitrate was absorbed much more readily than as sulphate.

Absorption of Mg was generally accompanied by an increase of serum inorganic P but little change in serum Ca.—R. Hill.

3139

HAGEN, P. and ROBINSON, K. W. **The influence of hyaluronidase on absorption from the colon.** *Med. J. Austral.*, 1953, i, 848–849. [Physiol. Dept., Univ. Queensland.]

Absorption was tested by injecting the test solution into the colon, which was tied off, after it had been thoroughly washed through with physiological saline, or with distilled water in the experiment with NaCl. Six guineapigs, weighing about 450 g., were used for each test; they were given a measured volume of the test solution, 3 with and 3 without hyaluronidase, 10 Schering units per 50 ml. solution. After 2 hr. the colon was removed and washed out and the contents were made up to volume and analysed.

Glucose was not absorbed from the colon at all whether hyaluronidase was present or not, and the quantities of propionic acid, methionine, amino acid hydrolysate and NaCl absorbed were uninfluenced by the presence of hyaluronidase.

CASTLE, E. J. **The rate of passage of foodstuffs through the alimentary tract of the goat. 1. Studies on adult animals fed on hay and concentrates.** *Brit. J. Nutrition*, 1956, **10**, 15–23. [Dept. Vet. Prevent. Med., Univ. Liverpool.]

Two experiments were made on each of 8 goats weighing from 26·6 to 57·3 kg., 6 castrated males and 2 females. All were kept in metabolism cages and fed on 400 g. calf nuts daily and meadow hay to appetite. For experiments each goat received 10 to 20 g. hay stained by boiling with basic fuchsin or brilliant green. Faeces were collected 11 hr. later, then every hour until stained particles were found, every 4 hr. for the next 2 days and then at longer intervals until no more stained particles were found. Coloured particles were collected on a gauze filter, counted and expressed in relation to dry weight of faeces.

In all the goats stained particles were first found in the faeces between 11 and 15 hr. after the meal of hay. The concentration rose sharply to a maximum after about 30 hr. and then fell to zero by the sixth or seventh day. Curves of excretion were sigmoid, and between the times at which 5 and 80 per cent. of the total recovery had been excreted the mean rate of excretion was 2·1 per cent. per hour and the range from 1·6 to 2·8 per cent. In all the goats 5 per cent. was excreted in about 16 hr., but the time taken to reach 95 per cent. excretion tended to be an individual characteristic. There was a negative correlation, just statistically significant, between feed intake and mean retention time. There was a significant positive correlation between time of 5 per cent. excretion and dry matter content of faeces. Mean retention time was not related to bodyweight.

RADEFF, T. and STOJANOFF, I. Über die Bewegungen des Pansens und den Mechanismus des Wiederkauens. [**Movement of the rumen and the mechanism of rumination.**] *Arch. Tierernährung*, 1955, **5**, 331–347. [Inst. Exp. Veterinärmed., Bulg. Akad. Wiss., Sofia.]

The cranial and caudal parts of the dorsal rumen sac contract simultaneously. The secondary contraction occurs in sheep on the average 13 sec. after the primary and 28·25 sec. before the next primary. The secondary contraction is always the weaker and may be absent, with some reduction in the interval between primary contractions. The secondary contraction affects the caudal sac most strongly, and is accompanied by eructation. Contractions of the ventral sac follow those of the dorsal sac, but are weaker. Two contractions of the ventral sac may occur for each one of the dorsal sac. During rumination, regurgitation is accompanied by a pause in respiration and occurs just before contraction of the dorsal rumen sac and reticulum. Chewing occupies the time of the secondary rumen contraction and swallowing occurs after the second contraction of the ventral sac.—D. Duncan.

AUGUSTO VALLENAS P., G. **Effects of the glycemic levels on rumen motility in the sheep.** *Amer. J. Vet. Res.*, 1956, **17**, 79–89. [Dept. Physiol., New York State Vet. Coll., Cornell Univ., Ithaca.]

The injection of glucose solutions, 0·7 to 1·0 g. per kg. bodyweight, into the jugular vein of sheep decreased the frequency of rumen movements and caused some depression of the strength of the contractions. The effect was considerable only with the higher dose. Insulin, 1 unit per kg. bodyweight, after an initial depression caused a large

increase in frequency. The changes after insulin appeared to have an inverse relation to blood sugar. The effect was reversed by injection of glucose. Emphasis is placed on the variability in the response to a given treatment even in the same animal, and possible mechanisms are discussed.

JOHNS, A. T. **Pasture quality and ruminant digestion. 2. Levels of volatile acids and ammonia in the rumen of sheep on a high-production pasture.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37**, 323–331. [Grasslands Div., D.S.I.R., Palmerston North.]

The pasture described in part 1 (see Abst. 2896, Vol. 26) was grazed by 2 sheep with rumen fistulae. There was no marked change through the year in rumen total volatile fatty acid, which ranged from 10·1 to 18·7 m*M* per 100 ml., or in percentage proportions of different acids, which were acetic 50 to 62, propionic 21 to 30, butyric 12 to 17 and C_5 acids 3 to 10. The high protein content of the pasture was reflected in high rumen ammonia levels, from 35 to 130 mg. per 100 ml., but there was no close relation with pasture variations. When the sheep were changed to a hay diet, rumen ammonia and volatile fatty acid levels fell. The proportion of acetic acid increased, that of butyric acid decreased and that of propionic acid remained relatively constant. Possible effects on animal metabolism are discussed.—J. L. Corbett.

3144

HOFLUND, S., HOLMBERG, J. and SELLMANN, G. **Investigations on fat digestion and fat metabolism in ruminants. 2. Feeding unsaturated fats to dairy calves. 3. Influence of the rumen flora on fat digestion by sheep.** *Cornell Vet.*, 1956, **46**, 51–53 ; 53–57. [Dept. Cattle Sheep Dis., Royal Vet. Coll., Stockholm.]

For part 1 see Abst. 5290, Vol. 25.

2. Young calves in which the rumen had not begun to function were fed until they were from 1 to 5 months old on a mixture of whole milk, skimmed milk and linseed oil emulsion to give a fat content of 5 per cent. Depot fat was taken from several sites and its content of linoleic and linolenic acids was studied spectrophotometrically after alkali isomerisation.

The proportions of linoleic and linolenic acids in subcutaneous, mesenteric and perinephric fat were higher than those normally found in the depot fats of mature ruminants ; the percentage of linoleic acid ranged from 3·4 to 6·1 and that of linolenic acid from 1·7 to 4·8. It is concluded that unsaturated dietary fat is absorbed unchanged by young calves lacking the rumen organisms which, in the older animal, effect the hydrogenation of unsaturated fatty acids.

3. A sheep with a permanent rumen fistula was fed to appetite on a diet of oat grits, wheat bran, molasses and hay. After 300 ml. of a 33 per cent. emulsion of linseed oil had been introduced into the rumen samples of rumen contents were withdrawn at 6, 12, 24, 36, 48 and 60 hr. for estimation of the linoleic and linolenic acid content of the fat. A similar experiment was made with 500 ml. of the linseed oil emulsion.

Linolenic acid disappeared from the rumen fat very rapidly, but the fall in linoleic acid content was much slower, demonstrating conversion of the trienoic to the dienoic acid by hydrogenation.

Similar experiments were made after introduction of 5 g. potassium chlorate or 0·25 g. of a fungicide into the rumen. No conclusion could be drawn from the experiment in which potassium chlorate was used to kill the " infusoria ", since the linseed oil emulsion probably broke down owing to weakened rumen contractions. The hydrogenation of linoleic acid was demonstrated after administration of the fungicide, though not as clearly as in the initial experiments, probably because of a disturbance in the symbiotic relations of the rumen organisms.—G. A. Garton.

3145

ANDERSON, C. M. **The metabolism of sulphur in the rumen of the sheep.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37**, 379–394. [Canterbury Agric. Coll., Lincoln.]

A ewe with a rumen fistula was fed to appetite on lucerne hay containing 0·28 per cent. total S. For experiments it was fed from 7.30 to 9.0 a.m. and then placed in a bare pen ; rumen contents were sampled 1½ hr. later and the substance to be studied was introduced. Further samples were taken at intervals thereafter. The capacity of the rumen was about 4 litres.

Sulphide, $Na_2S \cdot 9H_2O$, almost all disappeared from the rumen within 2½ hr. when given at about 113 μg. S per ml. contents, and over half disappeared within 30 min. Blood sulphide rose briefly and returned to normal within 1 hr. It was concluded that most of the sulphide, as H_2S, was absorbed through the rumen epithelium. Sulphate was given in doses of 30, 60 and 90 g. There was rapid reduction to sulphide, which reached its peak of concentration after 2½ hr. with the smallest and 5 hr. with the largest dose, and then declined steadily. The peak was 97 μg. S per ml. after the largest dose of sulphate, 2250 μg. S per ml. The increase in crude protein S was between 0·05 and 0·1 mg. per ml. and was not related to the amount of sulphate given. Sulphide concentration in the rumen was not affected by addition of 1·04 g. S as 100 g. casein or 1·34 g. S as 5 g. cystine.

In experiments *in vitro*, with washed suspensions of rumen microflora, production of sulphide from sulphate was not very sensitive to *p*H. Release of sulphide from casein and uptake of sulphide by micro-organisms were greatest at *p*H 6. Sulphide was utilised quite rapidly, but not as fast as sulphate was reduced. Cyanide added with sulphide was detoxicated, with production of thiocyanate.

Slices of liver and kidney from a sheep took up sulphide during incubation; the liver slices took up S at a rate equivalent to 0·6 g. sulphide per hr. for a whole liver of 600 g., and at this rate the liver could collect any sulphide likely to be absorbed from the rumen.

It was not found possible to produce signs of S deficiency in 4 sheep given KCN for 6 weeks.

COMPOSITION OF BODY FLUIDS AND TISSUES

BLOOD

3146

Rourke, G. M., Du Toit, C. H. and Wood, E. **Normal laboratory values.** *New Engl. J. Med.*, 1956, **254**, 29–35. [Chem. Lab., Massachusetts Gen. Hosp.]

Normal values, quantity of blood or other biological fluid required and reference to method are tabulated for a number of constituents of human blood and urine, with a few for cerebrospinal fluid and miscellaneous values.—W. M. Deans.

3147

Cottom, D. G. **Foetal haemoglobin and post-maturity.** *J. Obstet. Gynaecol. Brit. Empire*, 1955, **62**, 945–948. [St. Thomas's Hosp., London.]

The amount of foetal haemoglobin in umbilical cord blood was measured at 24 births by a modification of the method of Brinkman and Jonxis. The results are expressed as percentages of the Haldane standard. In babies born at term the average level was 70 per cent.; higher levels were obtained before term, and lower levels after term. The agreement between the foetal Hb levels and the calculated age suggested that the former might be useful as an objective index of maturity.

A. M. Thomson.

3148

Ruggieri, P. and Marchi, M. Ricerche sulla specificità antigene delle emoglobine umane normali (adulta e fetale) mediante precipitazione in agar. [**Antigenic specificity of normal human haemoglobins, adult and foetal, studied by precipitation in agar.**] *Riv. Ist. sieroterap. ital.*, 1955, **30**, 405–413. [Ist. Clin. Med., Univ. Rome.] English summary.

Immunological studies by diffusion in agar showed that Hb from an adult human subject contained a proportion of foetal Hb. Rabbits inoculated with crystalline human adult Hb produced 2 specific antibodies, one against adult and one against foetal Hb. Foetal Hb caused production of only one antibody.—D. Duncan.

Hawkins, W. W., Leonard, V. G. and Speck, E. **The total body hemoglobin in children and its relation to caloric and iron requirements.** *Metabolism*, 1956, **5**, 70–78. [Maritime Reg. Lab., Nat. Res. Counc., Halifax, N.S.]

Hb, heights and weights of 1800 children aged 6 to 17 years were measured. From these were selected children who were within ± 15 per cent. of both average height and average weight for their age and sex of Canadian children. About 2/3 met these standards. These observations were the basic data. Other values presented were obtained from the literature or computed from the basic data from relationships established in the literature; they were surface area, blood volume, total Hb, total Fe in Hb, total energy expenditure per hr., and ratios of total Hb to total energy expenditure per hr. and of oxygen available per hr. to oxygen expenditure.

In boys the ratio of Hb to energy expenditure increased from 2·4 at age 6 to 4·6 at age 17. In girls the ratio increased from 2·5 at age 6 to 3·4 at age 12 to 17.

Estimated metabolic Fe requirements, based on yearly increment and yearly loss, are tabulated by age and sex. In general Fe requirement of boys and girls increased with age up to puberty. Requirements of boys aged 13 to 15 exceeded those of girls of the same age in spite of menstrual losses in the girls.—F. C. Aitken.

Walker, A. R. P., Fletcher, D. C., Reynolds, P. A., Bersohn, I. and Sonnenfeld, E. D.

Reduction to normal levels of the high erythrocyte sedimentation-rates in apparently healthy South African Bantu men. *Nature*, 1956, **177**, 480–481. [Human Biochem. Res. Unit, S. African Inst. Med. Res., Johannesburg.]

In African mine-workers the mean red cell sedimentation rate (Wintrobe) was lower, comparable with normal values, in those who had been in employment for from 4 to 15 months than in others at the beginning of their service. For groups of different origin with, in brackets, the number of subjects the values at the beginning of service were: Shangaans (75) $11{\cdot}5 \pm 11$, Pondos and Xosas (47) 12 ± 9 and a tropical group (75) 29 ± 10 mm.; the corresponding values after the period were (25) $3{\cdot}5 \pm 2{\cdot}5$, (31) $3{\cdot}0 \pm 2{\cdot}5$, (30) $3{\cdot}5 \pm 4{\cdot}0$ mm. For a mixed group of 15 who were all studied both on arrival and after service the values were 16 ± 11 and $3{\cdot}0 \pm 2{\cdot}5$ mm.

By the common biochemical tests many showed liver dysfunction, but no explanation can be offered. It is thought that the change may be nutritional in origin, since the diet supplied by the mining companies is much better than that which the Africans are accustomed to in their homes.

Tanaka, T. and Rosenberg, M. M. **Effect of testosterone and dienestrol diacetate on hemoglobin levels of cockerels and capons.** *Poultry Sci.*, 1955, **34**, 1429–1437. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

3155

Thompson, M. D. **The serum protein pattern of African infants in Uganda.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1956, **50**, 77–81. [Mulago Hosp., Uganda.]

Data are tabulated for total protein, albumin and 4 globulin fractions for 120 estimations on samples of blood from 110 African infants in Uganda, all of whom had been exposed to malaria and among whom the proved incidence was 79 per cent. The mean values with standard deviations and ranges are given for the first month of age, for months 2 and 3 and thereafter at 3-monthly intervals and for the period 12 to 18 months. Frequency of sickling trait is also recorded.

The pattern of proteins in the first month is the same in Uganda as it is at birth in Europe and the United States and, as happens in these countries, there are changes during the first 9 months of age. In Uganda these changes give an adult pattern different from that in Europe and the United States (see Abst. 559, Vol. 26). The present work forms the basis of a study, now in progress, of the effects of protection from malaria.—D. Harvey.

3156

Yoshida, H. **Electrophoresis of sera of breast-fed infants and its relation to nutritional dystrophy of their mothers. Studies on the nutrition of children in Hirosaki area (22nd report).** *Tohoku J. Exp. Med.*, 1955, **63**, 69–79. [Dept. Paediat., Sch. Med., Hirosaki Univ.]

For earlier work see Abst. 4477, Vol. 23.

Estimations of total protein and electrophoretic analyses were made on sera from 101 infants in 6 groups. For 32 infants aged from 1 to 12 months, breast-fed by mothers without nutritional dystrophy, mean values were; total protein 6·05 g. per 100 ml., percentage distribution albumin 58·5, α-globulin 15·3, β-globulin 15·1, γ-globulin 10·9. For 18 infants of the same age and also breast-fed but by mothers with signs of nutritional dystrophy, corresponding average data were 6·40 g. and 50·5, 17·4, 16·0 and 15·9 per cent. For 25 infants aged from 13 to 24 months, partly artificially fed on food rich in carbohydrate and partly breast-fed by mothers without nutritional dystrophy, average data were 6·49 g. and 53·6, 16·3, 14·7 and 15·3 per cent.; for 6 infants aged from 16 to 24 months fed like these by mothers with nutritional dystrophy, 6·96 g. and 48·4, 19·2, 16·0 and 16·4 per cent. For

12 infants aged from 6 to 21 months and undernourished but without signs of disease, averages were 6·28 g. and 55·3, 14·5, 15·3 and 14·8 per cent. and for 8 infants aged from 3 to 20 months who had been breast fed for only a few months, of whom 5 had nutritional dystrophy and among whose mothers 4 were affected, 5·92 g. and 48·1, 15·3, 14·8 and 20·3 per cent. The findings are compared with those by Karte for German infants (Abst. 601, Vol. 24).

Children wholly breast-fed do not show signs of nutritional dystrophy, but in the blood of those whose mothers have the disease the electrophoretic pattern, with its fall in albumin and rise in γ-globulin, resembles that in children in whom the disease is clinically apparent.—D. Harvey.

MOGGI, P. and FRANCALANCIA, L. Fisiopatologia dei polisaccaridi legati alle proteine seriche nell'infanzia. [**Physiology and pathology of the polysaccharides bound to serum proteins in infancy.**] *Riv. Clin. pediat.*, 1955, **56**, 573–595. [Clin. Pediat., Univ. Florence.] English and French summaries.

Several methods for estimating polysaccharides were tested, and that of Dische (*Mikrochemie*, 1929, **1**, 33) with carbazole was selected. Polysaccharides and total protein were estimated in the blood serum of 55 healthy infants and children of all ages up to 12 years, of 13 premature infants and of 90 subjects with different diseases, and in the cord blood of 6 newborn infants and in the blood of their mothers. At ages from birth to 6 months, the mean values were for total protein 6·1 g. per cent. and for polysaccharides 97·1 mg. per cent., and at from 8 to 12 years the corresponding values were 6·82 and 109·8. Both values increased gradually with age so that the ratio between them remained almost constant.

3159

LIDDELOW, B. **Serum protein levels in normal non-pregnant and pregnant women.** *Med. J. Austral.*, 1953, ii, 332–334. [Dept. Pathol., Women's Hosp., Melbourne.]

Serum protein estimations, based on total Kjeldahl N, were made each month on from 20 to 25 normal pregnant women. Normal values for non-pregnant women were obtained from 23 blood donors of child-bearing age ; the mean value was 7·04 g. per 100 ml. The average values for the pregnant women were lower than those previously reported in the literature, possibly owing to differences in environment and diet. For the last 7 months of pregnancy the mean was below 6·5 g. per 100 ml. There was a progressive decline up to the eighth month, and then a small rise in the ninth month. Values previously reported in the literature showed the same trends but at a higher level. Large differences between the maximum and minimum values for each month emphasised the doubtful clinical importance of a slightly low serum protein value during pregnancy.

3160

POIDEVIN, L. O. S. **Preliminary report on amino acids and serum protein variations throughout pregnancy.** *Med. J. Austral.*, 1954, i, 105–107. [Univ. Adelaide.]

A group of over 100 pregnant women, including nearly equal numbers of primiparae and multiparae, was divided into those in whom pregnancy was normal with or without previous history of toxaemia, or in whom toxaemia was present in the current pregnancy. Samples of urine and blood were collected in the morning 5 times during pregnancy, in the labour ward, and 6 weeks after delivery. Amino acids were estimated by chromatography, a number being assigned to each spot according to the depth of colour produced with ninhydrin. Serum proteins were studied by paper electrophoresis. Normal values were obtained from non-pregnant healthy women of the same age group.

The amino acid content of the urine rose, and that of the serum fell, during the third trimester in both normal and toxaemic pregnancies, possibly owing to a fall in renal threshold. There was a general fall of total serum protein throughout both types of pregnancy, owing mainly to a fall of albumin, which was greater in toxaemic pregnancies. In normal pregnancies there was an increase of α_1-, α_2- and β-globulin and a decrease of γ-globulin. In toxaemic pregnancies the increase of α_1-globulin was greater and the decrease of γ-globulin less.—M. H. Pierce.

3161

ANDREU URRA, J. and RIVERO FONTÁN, J. L. Las proteinas del plasma en las colagenosis. [**Plasma proteins in collagen diseases.**] *Rev. clín. española*, 1955, **59**, 153–156. [1. Clín. Méd., Univ. Seville.] English, German and French summaries.

Serum total protein was within normal limits in 3 patients with generalised and one with localised scleroderma. Two of those with generalised scleroderma had low serum albumin and high γ-globulin ; the third showed falls in albumin and

γ-globulin after treatment with adrenocorticotropic hormone. A patient with Libman Sacks disease had low albumin and high γ-globulin, but one with chronic lupus erythematosus had normal serum proteins, and in one with dermatomyositis the changes were small. Six estimations in 15 months on serum from a patient with Weber Christian disease or recurrent febrile nodular panniculitis showed fluctuations with treatment. It is concluded that abnormal serum protein levels in collagen diseases are a result and not a cause of the diseases.—D. Duncan.

3162

BELEN'KII, N. G., KRYLOVA, N. N., CHERTKOV, I. L. and ZUEVA, L. D. Izuchenie tzirkulyatzii v organizme belkov lechebnoi syvorotki s pomoshch'yu radioioda (I 131). [**A study of the circulation of the proteins of medicinal serum with the help of radio-iodine (^{131}I).**] *Dokl. Vses. Akad. Sel'skokhoz. Nauk V.I. Lenina*, 1955, No. 4, 34–36.

Blood serum proteins of dog and rabbit were labelled with ^{131}I by incubation of serum for 24 hr. with labelled KI, after which free I was removed by dialysis against tap water and the proteins were incorporated into fresh serum. The labelled serum was given intravenously to 9 rabbits in doses of from 3 to 10 ml. per kg. bodyweight, and the radio-activity of blood samples was estimated after 1, 10 and 30 min. and 1, 2, 3, 24, 48 and 96 hr. A third of the labelled protein remained in the circulation 3 hr. after the injection and 10 per cent. was still present after 4 days. In 5 rabbits killed 96 hr. after the injection, there were individual differences in the distribution of radioactivity among the organs, but high concentrations were found most often in the lungs, liver and kidney.

Labelled serum was given by vein to 2 dogs in doses of 11 and 13 ml. per kg. bodyweight and the radio-activity of blood samples was estimated 5 min. and 1, 3, 6, 24 and 48 hr. later. After 6 hr. 70 per cent. of the ^{131}I injected was still in the circulation, and 30 per cent. after 48 hr. The dogs were then killed and the greatest amounts of radioactivity were found in the lungs, liver and spleen, all organs which have an active part in metabolism of proteins.

The rate of removal of injected proteins from the circulation is thought to be about the same in man as in the dog.—H. Scherbatoff.

3163

COHEN, S., HOLLOWAY, R. C., MATTHEWS, C. and MCFARLANE, A. S. **Distribution and elimination of ^{131}I- and ^{14}C-labelled plasma proteins in the rabbit.** *Biochem. J.*, 1956, **62,** 143–154. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

The rate of elimination of protein labelled with ^{131}I and its distribution between intra- and extravascular pools varied considerably in rabbits given labelled protein intravenously. This was due more to variation between animals than to differences in the labelled protein. Homologous and autogenous plasma were indistinguishable in this respect.

When plasma proteins were labelled with ^{131}I or ^{14}C equilibration times were similar. Plasma specific activity declined exponentially during the 3 to 4 weeks of the experiment and fibrinogen, globulin and albumin were eliminated in that order of decreasing rate. The biological half-lives of plasma proteins were similar when measured with ^{131}I or ^{14}C. ^{131}I detached from plasma protein was rapidly excreted in the urine and provided an accurate measure of the rate of elimination of protein.

It is concluded that the distribution and elimination of albumin and globulin *in vivo* as estimated with plasma labelled with ^{131}I was similar to that of proteins labelled with ^{14}C.—A. Hepburn.

QUINCKE, E. Vergleichende Messung der Konzentrationen des freien Methionins im Serum und in der Leber von Kaninchen. [**Comparative measurements of the concentration of free methionine in serum and liver of rabbits.**] *Biochem. Ztschr.*, 1956, **327,** 383–392. [Med. Klin., Univ. Cologne.]

Four normal rabbits fasted for 12 hr. each received intravenously 100 μg. L-methionine labelled with from 0·5 to 2·4 mC of ^{35}S; this dose represents less than 1 per cent. of the total free methionine in the body. After 1 or 1½ hr. the chest was opened under ether narcosis and 80 ml. blood was obtained by heart puncture, and then the liver was quickly removed and freeze-dried. Specific activity and ^{35}S activity of free methionine in serum and liver fluid were estimated by an indirect method.

The concentration of free methionine in serum and in liver fluid was nearly the same.

The method, which is described, is supposed to avoid errors occurring in direct estimation and especially enzymic liberation of methionine from liver proteins.—D. Duncan.

CIPOLLONI, C. and PACI, A. La lipemia nel lattante in condizioni fisiologiche. [**Blood lipids in the infant under physiological conditions.**] *Riv. Clin. pediat.*, 1955, **56,** 366–377. [Ist. Clin. Pediat., Univ. Pisa.] English and French summaries.

Total lipids, phosphatides, glycerides and 2 steroid fractions, one giving the Liebermann Burchard reaction and not precipitated by digitonin, and the other precipitated by digitonin, were estimated in the blood plasma of 35 infants between 3 and 12 months of age, breast-fed or artificially fed. Blood samples were taken 6 hr. after the last meal. All the values are tabulated. There were wide variations. The mean values in mg. per cent. were for total lipids 515 with range 363 to 642, phosphatides 188, 124 to 285, glycerides 104, 64 to 194 and total steroids 128, 70 to 181. There was no difference between the values for breast-fed and artificially fed infants.

PATERSON, J. C., CORNISH, B. R. and ARMSTRONG, E. C. **The serum lipids in human atherosclerosis. An interim report.** *Circulation*, 1956, **13,** 224–234. [Clin. Invest. Unit, Westminster Hosp., London, Ont.] Interlingua summary.

Serum lipids were estimated serially in 800 patients permanently confined to hospital, of whom some 550 were over 50 years of age. Chemical and morphological examinations were made on arterial tissue in 50 post-mortem studies and the degree of atherosclerosis was estimated.

Only increases in the cholesterol : phospholipin ratio and, possibly, the Sf 0–12 class of lipoproteins showed any relation to atherosclerosis.

The difficulty of assessing the severity of atherosclerosis in post-mortem material is discussed.

EVANS, J. D., WALDRON, J. M., OLEKSYSHYN, N. L. and RIEMENSCHNEIDER, R. W. **Polyunsaturated fatty acids in normal human blood.** *J. Biol. Chem.*, 1956, **218,** 255–259. [Sch. Med., Temple Univ., Philadelphia, Pa.]

Blood samples were taken from the antecubital vein of 7 young men and separated into cells and plasma, the polyunsaturated fatty acid content of each of which was estimated by the method of Herb and Riemenschneider (Abst. 66, Vol. 24).

Although the I value of plasma lipids and cell lipids was of the same order of magnitude, average 108 and 101, respectively, the percentage distribution of individual fatty acids was characteristically different. The average proportion of each acid, expressed as a percentage of the total fatty acids in plasma and cells, was: linoleic 25·0 and 7·84, linolenic 1·14 and nil, arachidonic 7·14 and 13·1, pentaenoic 1·45 and 2·87, hexaenoic 2·32 and 4·11.

KEYS, A., ANDERSON, J. T. and MICKELSEN, O. **Serum cholesterol in men in basal and non-basal states.** *Science*, 1956, **123,** 29. [Lab. Physiol. Hyg., Sch. Pub. Health, Univ. Minnesota, Minneapolis.]

Serum cholesterol was estimated in healthy men in the basal fasting state and 2, 3, 4 and 7 hr. after an ordinary breakfast or one including cholesterol emulsified in scrambled egg. During the test the men were either relatively inactive or doing moderately vigorous work on the treadmill or gardening. In the inactive subjects, serum cholesterol rose after the meal; in the active it was unaltered or fell. The rise in terms of total cholesterol in blood in 2 series of tests was greater than all the cholesterol in the meal. The rise is interpreted as an increase of lipoprotein to meet the demand for transport of newly absorbed fat. During exercise the rise in rate of blood flow and removal of nutrients to meet the increased needs explains the absence of a rise of lipoprotein and so of cholesterol.

The difference between basal and non-basal levels is so small as to be unimportant in comparative studies, especially of active subjects, but may explain part of the difference in susceptibility to coronary disease between active and sedentary subjects.—I. Leitch.

3173

MICHALEC, Č. **The nature of cholesterol esters in human blood serum.** *Biochim. biophys. Acta*, 1956, **19**, 187–188. [Central Biochem. Labs., Univ. Hosp., Prague.]

Cholesterol and cholesteryl esters from human blood serum were separated by paper chromatography as described earlier (Abst. 1439, Vol. 26). Paper chromatography of the component fatty acids of the esters on Whatman No. 3 paper impregnated with 10 per cent. (v/v) paraffin oil in ether and acetic acid as the mobile phase indicated the presence of palmitic, oleic and linoleic acids.

BRUCK, E. and WEINTRAUB, D. H. **Serum calcium and phosphorus in premature and full-term infants. A longitudinal study in the first three weeks of life.** *Amer. J. Dis. Child.*, 1955, **90**, 653–668. [Statler Res. Labs., Child. Hosp., Buffalo, N.Y.]

Serum Ca, inorganic P, phosphatase and K, and blood and serum *p*H and CO_2 were estimated in samples taken before the first feed and at intervals during the first 3 weeks of life from 51 premature and 21 term infants; the cord blood of 41 of the infants was examined. The feeds for the premature infants consisted of an Alacta preparation, evaporated milk, human milk or mixed or alternating human and cow's milk; all received 1250 "units" vitamin D daily in calciferol and 50 mg. ascorbic acid, starting on the eighth day of life. The feeds for the term infants consisted of whole cow's milk, human milk, or mixed or alternating human and cow's milk; no vitamin supplement was given except to one sick infant.

Serum Ca was, in general, considerably lower and fluctuated more widely in the premature than in the term infants. The lowest Ca level recorded was before the infant was fed; the longer the fast the lower, in general, the serum Ca. There was no significant difference between premature and term infants in serum inorganic P; when fasting was prolonged for more than 36 hr. or when cow's milk was given the P level rose, but after human milk it fell. In 69 per cent. of the intervals between the taking of blood samples from each individual infant the Ca level rose whether the P rose or fell; in 31 per cent. the Ca level fell, usually with a rising P level. In individual infants the curves of Ca and P ran parallel as often as in opposite directions. When the infants were fed on human milk, serum Ca consistently rose; serum P rose in about one-third and fell in two-thirds of the infants. When cow's milk was given, Ca rose in 60 per cent. and fell in 40 per cent. of the infants; P rose in 73 per cent. and fell in 27 per cent. The mean Ca and the mean P on cow's milk were higher than before feeding. The serum phosphatase levels were not indicative of rickets. The minimum Ca level attained was not related to birthweight within the range between 1400 and 2500 g. The rate of growth during the sampling period could not be evaluated from the weight gain and could not be correlated with serum Ca values. The Ca and P levels in cord blood showed no relation to the subsequent values. Few of the premature infants with low serum Ca had any commonly recognised sign of tetany. The correlation of these signs with the Ca level at the time of observation was not significant statistically. In 6 infants who were ill with other diseases serum Ca was below 8 mg. per 100 ml. Three infants died; all had signs and serum Ca levels of tetany. The *p*H and K levels had no statistically significant effect on the presence or absence of signs of tetany in patients with low serum Ca.

DAS GUPTA, S. K. and SINGH, M. **Studies on serum sodium and potassium levels and on the twenty-four hours' urinary excretion of 17-ketosteroids in healthy adults.** *Indian J. Med. Res.*, 1956, **44**, 31–36. [Dept. Biochem., Med. Coll., Amritsar.]

Average serum Na in 15 healthy men in the Punjab was 326 $\pm$ 3 mg. and in 17 women 323 $\pm$ 1 mg. per 100 ml. Corresponding figures for K were 19·2 $\pm$ 0·3 and 18·3 $\pm$ 0·2 mg. per 100 ml. Excretion of 17-ketosteroids was 16·94 $\pm$ 0·91 and 8·56 $\pm$ 0·75 mg. daily, respectively.

J. S. Thomson.

3176

HASHIMOTO, T. **Protein-bound iodine levels in children with nutritional dystrophy. Studies on the nutrition of children in Hirosaki area (26th report).** *Tohoku J. Exp. Med.*, 1955, **63**, 103–107. [Dept. Paediat., Sch. Med., Hirosaki Univ.]

Protein-bound I (PBI) of sera from children with nutritional dystrophy was estimated. The average PBI in the sera of 8 healthy children was 6·04 μg. per cent. $\pm$ 0·89. The 35 boys from 8 to 10 years old with nutritional dystrophy were divided into 2 groups according to the severity of the clinical signs. In 11 of the 21 boys more severely affected and in 2 of the 14 others, PBI was below 4 μg. per cent. As very low serum albumin has been found in children with nutritional dystrophy, low PBI may be evidence of depressed thyroid function or of low serum albumin; this is to be the subject of further investigation.

PALACIOS MATEOS, J. M. Valor clinico de la determinacion simultanea de cobre y hierro en el suero. [**Clinical value of simultaneous estimation of copper and iron in serum.**] *Rev.*

clín. española, 1955, **59**, 78–82. [Inst. Invest. Méd., Madrid.] English, German and French summaries.

Fe and Cu were estimated simultaneously in serum from 15 normal subjects, 9 men and 6 women, and from 47 patients with a variety of disorders.

Mean values, in μg. per 100 ml., were for the normal subjects Fe 139·3 and Cu 137·5; for men 140·7 and 126·0, for women 138·0 and 149·0. In epidemic hepatitis the mean values for 10 patients were 252·3 and 172·8, *i.e.*, a large increase in Fe and a moderate increase in Cu. Seven subjects with cirrhosis had means of 168·2 and 277·8, a moderate increase in Fe and a large increase in Cu. In 3 patients with obstructive jaundice both Fe and Cu were normal. In 3 with haemochromatosis both values were high, 210 and 337·6. Cu was very low, mean 61·3, in 3 patients with Wilson's disease. Values are given for several other disorders.

It is suggested that such analyses have a clinical value, *e.g.*, in differential diagnosis of the 3 liver disorders named.—D. Duncan.

HUISMAN, T. H. J. Onderzoek naar het gehalte aan verschillende aminozuren van de liquor cerebrospinalis. [**Study of the amount of different amino acids in cerebrospinal fluid.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99**, 3357–3361. [Kinderklin., Acad. Ziekenhuis, Groningen.] English summary.

Amino acids in human urine, plasma ultrafiltrate and cerebrospinal fluid ultrafiltrate were compared by chromatographic methods. Most of the amino acids found in plasma were present in the cerebrospinal fluid in concentrations of 1 mg. per litre or less. Glutamine and glutamic acid alone were in much higher concentrations than in plasma. It is concluded that cerebrospinal fluid is not derived from plasma by simple filtration, but that there is a selective barrier, probably in the choroid plexus. The possible significance of the high concentration of glutamic acid is discussed briefly.—D. Duncan.

ANTONINI, E., CASORATI, V. and CRIFÒ, S. Amino-acidi della perilinfa. [**Amino acids of perilymph.**] *Experientia*, 1955, **11**, 496–497. [Inst. Chim. Biol., Univ. Rome.]

Perilymph was obtained from young horses 15 to 30 min. after death; it was collected with a capillary pipette through the fenestra rotunda, and each ear yielded 0·015 to 0·025 ml. Samples of blood and cerebrospinal fluid were taken from the same horses. Two-dimensional chromatography on paper permitted identification of amino acids.

Aspartic acid, glutamic acid, phosphocolamine, glycine, serine, taurine, threonine, alanine, glutamine, lysine, arginine, γ-aminobutyric acid, proline, valine, leucine, tyrosine and phenylalanine were identified. The composition was much more like that of blood than that of cerebrospinal fluid.

3185

GORE, J. T. **Factors influencing the physical and chemical properties of saliva.** *J. Dent. Res.*, 1956, **35**, 102–108. [Univ. Pennsylvania, Philadelphia.]

The concentration of carbohydrate in whole saliva collected during 24-hr. periods from the author on a restricted carbohydrate intake rose from 6 p.m. until 2 p.m. The concentration in parotid saliva remained low and fairly constant, but that in mandibular saliva, which was much greater, rose until 10 p.m. and remained high during the night. Single meals high in carbohydrate temporarily increased the concentration in the whole saliva. The rate of secretion of saliva declined until about 6 a.m., then increased sharply. The rate of secretion of mandibular was on the average less than that of parotid saliva.

These results and previous work (Absts. 513, 4747, Vol. 8; 2583, Vol. 13) seemed to indicate that a high-carbohydrate diet increased the carbohydrate concentration in whole saliva as well as the ratio of the rate of secretion of mandibular : parotid saliva, especially during the night.

The most reliable tests were made on saliva collected in the early morning after fasting. Smoking, talking, movement of the tongue, lips and cheeks and physical activity may increase the rate of secretion. The preparation of the mouth and the method of collecting saliva influence the chemical and physical properties of the saliva.

McCance, R. A. and Widdowson, E. M. **The chemical structure of the body.** *Quart. J. Exp. Physiol.*, 1956, **41**, 1–17. [Med. Res. Counc. Dept. Exp. Med., Univ. Cambridge.]

This is the text of the Sharpey-Schafer Memorial Lecture given at Edinburgh University in October 1955 by Professor McCance.

The main part deals briefly with the effect of development and nutrition on the water, N, K and Na in the body.

During development the percentage of total and extracellular water in the body decreases and the N increases. The N : K ratio increases. Further work showed that K in the serum of man and pig decreased considerably from foetus to adult, but protein increased and Na also to a slighter extent. The N : K ratio increased similarly in human and pig muscle and also the N : P ratio; total and extracellular water decreased. Liver and heart cells altered similarly with development, but reached adult composition at a much earlier age. The composition of red cells did not appear to change.

Underfeeding leads to loss of fat and increase in the percentage of water, chiefly extracellular water, in the body. Muscles from cockerels undernourished from an early age were shown to contain more extracellular fluid than those of day-old chickens. Similar but smaller changes were produced by underfeeding at a later age. The N : K ratio in muscle from several species and in whole bodies was not affected by underfeeding and increased during development. Weanling rats fed on a low-protein diet of cassava and bananas such as that which produces kwashiorkor in African babies did not show a change in the N : K ratio in the muscles.—A. Hepburn.

Trotter, M. and Peterson, R. R. **Ash weight of human skeletons in per cent. of their dry, fat-free weight.** *Anat. Rec.*, 1955, **123**, 341–358. [Dept. Anat., Sch. Med., Washington Univ., St. Louis, Mo.]

The long limb bones of 10 white men and the complete skeletons of 6 additional white men and 1 negro were available for study. The technique is described in detail and discussed. Tables are presented showing the ash weight as percentage of dry fat-free weight in the bones from each body.

The men ranged in age from 41 to 89 years. In long limb bones, but not in other bones, the percentage ash weight was slightly lower in older than in younger subjects. In 6 complete skeletons the total percentage of ash varied from 64·8 to 66·9; in the seventh the percentage was 54·5. In 2 complete skeletons the percentage of ash of all bones fell within close range of each other. In 5 skeletons there were bones with ash weights 5 per cent. or more below that of the complete skeleton.

Walker, A. R. P., Strydom, E. S. P., Reynolds, P. A. and Grobbelaar, B. G. **The composition and density of thoracic vertebral bodies from South African Bantu adults habituated to a very high iron intake.** *S. African J. Lab. Clin. Med.*, 1955, **1**, 254–262. [Human Biochem. Res. Unit, S. African Inst. Med. Res., Johannesburg.]

For previous work see Abst. 1058, Vol. 24.

Vertebral bodies, mainly from the fifth thoracic vertebrae, were removed at consecutive post-mortem examinations from 77 Bantu and 11 European adults. The primary cause of death was not siderosis or osteoporosis.

The vertebrae from 31 Bantu found to have moderate siderosis and from 12 Bantu with severe siderosis, including 2 with collapsed vertebrae, contained on the average 433 $\pm$ 272 and 1430 $\pm$ 381 mg. per cent. Fe on a dry weight basis, compared with 33·4 $\pm$ 14 for the Europeans. Siderosis was not necessarily associated with low mineral density, as there was no apparent correlation between concentrations of Fe and of ash or Ca on either a percentage or a volume basis.

Siderosis is thought not to be the principal cause of collapse and osteoporosis of the vertebrae occasionally found in the adult Bantu.—A. Hepburn.

CASTER, W. O., PONCELET, J., SIMON, A. B. and ARMSTRONG, W. D. **Tissue weights of the rat. 1. Normal values determined by dissection and chemical methods.**

CASTER, W. O. and ARMSTRONG, W. D. **2. Changes following 700 r total body x-irradiation.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 122–126; 126–129. [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

1. The data tabulated were obtained by a combination of partial dissection and chemical analysis. The procedure is described.

2. The loss of bodyweight after total body exposure to X-rays was due mainly to loss of muscle mass. The percentage of weight lost was greatest in spleen, thymus and marrow, but these tissues are too small to have an appreciable effect on change in total bodyweight.—F. C. Aitken.

3190

WATERLOW, J. C. and WEISZ, T. **The fat, protein and nucleic acid content of the liver in malnourished human infants.** *J. Clin. Invest.*, 1956, **35,** 346–354. [Trop. Metabol. Res. Unit, Med. Res. Counc., Jamaica, B.W.I.]

Liver samples obtained by biopsy from 12 severely undernourished infants with fatty livers showed a great excess of fat, a slight but doubtful increase of water and a high glycogen content. The protein and ribonucleic acid contents of the biopsy specimens were measured and related to deoxyribonucleic acid. These measurements were made soon after the infants were admitted to hospital and were repeated after one or 2 months; on admission the babies were put on a diet of diluted skimmed milk calculated to provide about 8 g. protein daily, but after biopsy the strength of the milk mixture was increased by stages until an intake of 2 to 3 pints of cow's milk daily had been achieved; supplementary foods were then given. When it was assumed that the deoxyribonucleic acid content per cell and per liver remains constant, the results showed that at the time of admission the infants had on the average lost 40 per cent. of their liver protein and ribonucleic acid. Evidence suggesting that the assumption of constant deoxyribonucleic acid is not valid in this study is discussed; the errors introduced by the assumption tended to decrease, rather than to exaggerate, the differences found between biopsies before and after treatment. It is concluded that measurements of this type give useful statistical information about a group of subjects, but are of little value as a guide to the state of an individual.—G. F. Garton.

BRÜCKEL, K. W. and PIETZONKA, H. Über den Fett- und Eisengehalt der Leber. [**The fat and iron content of the liver.**] *Klin. Wochenschr.*, 1956, **34,** 102–103. [Städt. Krankenhaus, Stuttgart, Bad Cannstatt.]

Estimation of the fat and iron content of liver material obtained by biopsy from 25 men and 12 women showed that in moderately or severely fatty livers the Fe content was generally low, and in specimens showing siderosis the fat content was usually low.—L. Wills.

3192

BRÜCKEL, K. W., PIETZONKA, H. and PFEILSTICKER, K. Zur Klinik und Histochemie des Eisenstoffwechsels der Leber. [**Clinical importance and histochemistry of iron metabolism in the liver.**] *Deutsch. med. Wochenschr.*, 1956, **81,** 132–135. [Städt. Krankenhaus, Stuttgart, Bad Cannstatt.]

After a discussion of the significance of serum Fe in diagnosis, material obtained at liver biopsy or immediately after death from 32 [number deduced from diagram] male and 23 female patients, mostly with liver damage of one kind or another, is reported on. Siderin was demonstrated histochemically (see Brückel and Pietzonka, *Klin. Wochenschr.*, 1955, **33,** 1102 and preceding Abst.). The findings are shown in diagrams, with 4 degrees of Fe deposition and 4 degrees of fatty infiltration, and are discussed in detail. There tended to be 2 types of distribution of Fe, much siderin with low total Fe, especially in the final stages of cirrhosis, or high total Fe with little siderin. Siderin deposits were seldom found in women. In the authors' view, disturbance of Fe-protein metabolism in the liver and fatty infiltration are independent pathological processes.

RUSSELL, J. A. and BLOOM, W. L. **Extractable and residual glycogen in tissues of the rat.** *Amer. J. Physiol.*, 1955, **183,** 345–355. [Dept. Biochem., Div. Basic Sci., Emory Univ., Emory University, Ga.]

Tissues used were from young adult rats maintained on Purina laboratory chow. After extraction of liver and muscle samples with 10 per cent. trichloroacetic acid, the carbohydrate remaining in residues was liberated from the protein by digestion with hot concentrated alkali. This material had the properties of glycogen. The quantities of glycogen found in the residues from trichloroacetic acid extraction of muscle, heart, diaphragm and liver were in substantial agreement with the amounts of residual glycogen indicated by difference between total glycogen, obtained by alkali digestion, and extractable glycogen.

When muscle, heart or liver samples were extracted with tungstic, metaphosphoric or sulphosalicylic acid or by boiling followed by adjustment to *p*H 5 the same amounts of glycogen were obtained as when they were extracted with trichloroacetic acid ; extraction with water alone or with dilute H_2SO_4 yielded much larger proportions of the glycogen present. Precipitation of the proteins in the latter extracts was accompanied by removal of consistent quantities of glycogen with the protein.

Parallel estimations were made of total glycogen and glycogen extractable by trichloroacetic acid in the gastrocnemius muscle, heart, diaphragm and liver of rats in a variety of conditions. The proportion of extractable glycogen was not constant but varied in consistent manner with the amount of glycogen present. In muscle and heart and at higher concentrations of glycogen in liver and diaphragm, the extractable glycogen ran parallel to the total glycogen over a wide range of concentrations while the residual glycogen remained relatively constant in amount. With decreasing concentrations of glycogen in liver and diaphragm both fractions were diminished, but the extractable portion fell more rapidly than the residual, so that at extremely low concentrations very little of the glycogen was extractable with trichloroacetic acid. The residual or non-extractable glycogen of muscle and heart was susceptible to some extent to breakdown *in vivo* but appeared to be less labile than the extractable fraction.—G. F. Garton.

CORSINI, F. Alcuni dati chimici sul fegato di cavie dopo inanizione. **[Some chemical data on the liver of guineapigs after starvation.]** *Boll. Soc. ital. Biol. sper.*, 1955, **31,** 578–579. [Ist. Clin. Pediat., Univ. Bologna.]

Three guineapigs were deprived of food until they died after 5 days. Their livers and those of 3 guineapigs not starved were analysed for N, P fractions and pentoses. In the starved guineapigs the non-precipitable N showed no difference, the precipitable N very little, the total acid-soluble P a decrease, the inorganic P a moderate increase, and the organic acid-soluble P a marked decrease. There was a great decrease in the amount of pentoses.—E. M. Hume.

MAIBAUER, D. and HERKEN, H. Vorkommen und Anreicherung von Inosit und Inositderivaten in den Zellfraktionen von Gehirn und Leber. **[Occurrence and accumulation of inositol and inositol derivatives in cell fractions of brain and liver.]** *Arch. exp. Pathol. Pharmakol.*, 1956, **227,** 456–466. [Pharmakol. Inst., Freie Univ., Berlin.]

Meso-inositol was estimated with *Saccharomyces carlsbergensis* 4228 ATCC 9080 by an adaptation of the method of Atkin *et al.* (György, Title 1253, Vol. 20).

When slices of organs, mostly from rats and mice but sometimes from rabbits and cats, were incubated aerobically or anaerobically for 1½ to 2 hr. at 37° C. in Ringer solution with phosphate buffer and glucose in a Warburg apparatus, brain and ganglia of the sympathetic nervous system gave up from 2 to 4·4 μg. inositol per mg. dry weight to the medium, but liver, pancreas and thyroid gave none. Subsequent hydrolysis of brain slices with HCl yielded a further 3 μg. inositol, in agreement with the results of Taylor and McKibbin (Abst. 4423, Vol. 23) ; but their different method apparently did not include the readily available fraction, so that the total amount of inositol in the central nervous system is higher than has hitherto been recorded.

Cell fractions from liver and brain of rats were then investigated. Nuclei, mitochondria, microsomes and cell plasma from liver all contained inositol, but free inositol was found only in the cell plasma. Cell plasma from brain contained 10 times as much as that from liver and 100 times as much as blood serum, and considerable amounts, both free and bound, were found in the other brain cell fractions.

The results are discussed with reference to the role of inositol in the metabolism of brain phospholipins and in the functioning of nerve cells.

DEL VECCHIO, A., KEYS, A. and ANDERSON, J. T. **Concentration and distribution of cholesterol in muscle and adipose tissue.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 449–451. [Lab. Physiol. Hyg., Univ. Minnesota.]

Cholesterol was estimated in muscle and in adipose tissue which had been separated by dissection from beef, veal, pork, sucking pig, mutton, lamb, chicken, rabbit and human abdominal wall.

The cholesterol content of muscle tissue, apart from associated fat, in all adult mammals studied and in the dark flesh of chickens was 40 to 50 mg. per 100 g. Higher values, 113 mg. and 138 mg. per 100 g., were found for 2 elderly human subjects aged 65 and 67 ; white meat of chickens contained about 30 mg. cholesterol per 100 g.

A general tendency was for muscle cholesterol to be considerably higher in young, growing animals than in adults of the same species. The cholesterol content of adipose tissue was always greater than that of the corresponding muscle, and was also more variable.—G. A. Garton.

3197

DEL VECCHIO, A., KEYS, A. and ANDERSON, J. T. Sull'esistenza di complessi lipoproteici nel tessuto muscolare. [**Lipoprotein complexes in muscular tissue.**] *Arch. Sci. biol., Bologna,* 1955, **39,** 705–710. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

A dry preparation of myosin from the muscle of a rabbit contained some lipids, including cholesterol. The close similarity in concentration of cholesterol obtained from 2 preparations suggested that the cholesterol exists as a lipoprotein complex with the myosin.—D. Duncan.

CHEEK, D. B. and WEST, C. D. (with GOLDEN, C. C. and DOYLE, E. M.) **An appraisal of methods of tissue chloride analysis : the total carcass chloride, exchangeable chloride, potassium and water of the rat.** *J. Clin. Invest.*, 1955, **34,** 1744–1755. [Child. Hosp. Res. Found., Cincinnati, Ohio.]

Blood samples were taken from 45 rats after intramuscular injection of NaBr. The rats were then killed and the dried fat-free carcases were ground and analysed for total chloride by 3 methods : the open Carius method with digestion of the tissue at 104° to 105° C. by boiling on a hot-plate, or at 96° to 97° C. by immersion in boiling water, and an alkaline ash procedure with estimation of Cl by the micro-diffusion method of Conway. The last method gave the most reproducible results and the best recovery of added chloride. Values obtained by digestion on a hot-plate were frequently low. The temperature during digestion appeared to be important.

The exchangeable Cl estimated from the volume of distribution of Br in the serum was nearly equal to the total carcase Cl. Neither was appreciably affected by the substitution of isotonic saline for drinking water in the diet.

Total body Cl, water and K bore a simple linear relation to lean body mass.—A. Hepburn.

DUCTLESS GLANDS AND HORMONES

3204

CAMPOS ZAMORANO, H. Restricción alimenticia y glándulas endocrinas en el conejo. [**Restricted diet and endocrine glands in the rabbit.**] *Rev. Chilena Educac. fis.*, 1955, **21,** 1074–1079.

Seventeen male and 31 female rabbits, 30 to 50 days old at the beginning, were divided into 3 groups and given normal diets in which, over the experimental period of 18 days, intake increased from 175 Cal. and 10 g. to 964 Cal. and 56 g. (to appetite): 151 and 8 to 481 and 28 (partial restriction) and 71 and 4 to 212 and 12 (severe restriction). In the groups in that order, final weights of skeleton were 94·5, 67·3 and 42·9 g., and the ratios to bodyweight $\times 10^3$ were 48, 45 and 49; of pituitary 18, 14 and 11 mg. and the ratios $\times 10^6$ were 9, 9 and 11; of thyroid 137, 147 and 70 mg. and 69, 99 and 77; of adrenals 221, 235 and 182 mg. and 116, 160 and 209; of ovaries 405, 347 and 283 mg. and 219, 228 and 317. Sexual maturity, as judged by the reaction of the ovary to (chorionic) gonadotropin, was not delayed by restriction of food. There were 2 deaths in each of the first 2 groups and 11 in the severely restricted.

3205

GILLMAN, J. and GILBERT, C. **The participation of the adrenal and thyroid in fat metabolism in hypophysectomised baboons (*Papio ursinus*).** *Experientia*, 1956, **12,** 65–66. [Dept. Physiol., Univ. Witwatersrand, Johannesburg.] German summary.

The results were for 30 baboons, 3 normal, 9 adrenalectomised, 13 thyroidectomised and 5 hypophysectomised (1 also thyroidectomised). All the hypophysectomised baboons received 0·5 mg. thyroxine 3 times weekly.

Bilateral adrenalectomy led to progressive depletion of the fat depots and loss of weight. Thyroidectomy was not associated with development of fatty liver even after 4 years. Hypophysectomised baboons gained weight steadily, but did not develop fatty livers even after 8 months. The bodyweight decreased for 7 to 14 days during daily administration of cortisone or adrenocorticotropic hormone; it then increased as appetite improved, and large quantities of subcutaneous fat were deposited. Adequate amounts of thyroxine prevented this increase of weight and reduced the amount of blood lipids. Withdrawal of cortisone and thyroxine rapidly produced fatty livers.—A. Hepburn.

3206

BOLLIGER, A. **The adrenals of the koala (*Phascolarctos cinereus*) and their alleged relationship to eucalyptus leaf diet.** *Med. J. Austral.*, 1953, i, 917–919. [Gordon Craig Res. Lab., Dept. Surg., Univ. Sydney.]

It has been claimed that the leaf-eating marsupials, koala and common possum (*Trichosurus vulpecula*), possess constitutionally rudimentary or hypofunctional adrenals, and that the low activity of the glands may be associated with a diet of eucalyptus leaves. The adrenals of 3 koalas and 60 possums were therefore examined.

The adrenal tissue of the koalas constituted from 0·006 to 0·008 per cent. of the bodyweight, and of the possums from 0·008 to 0·015 per cent., compared with from 0·01 to 0·02 per cent. in most mammals. The adrenals of the koala were histologically of the usual mammalian pattern. Contrary to belief, all the possums examined possessed two adrenal glands, and the zona glomerulosa was always present in both males and females. Possums were kept healthy for several years in the laboratory on a diet without eucalyptus leaves.

No evidence was found to suggest that there is adrenal insufficiency in koalas, or that eucalyptus leaves contain any substance resembling adrenal hormone.—M. H. Pierce.

3207

GOLDMAN, M. L., RONZONI, E. and SCHROEDER, H. A. **The response of the adrenal cortex of the rat to dietary salt restriction and replacement.** *Endocrinology*, 1956, **58,** 57–61. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

The findings in 96 young male rats are described. A diet with only 0·0047 per cent. sodium produced in 4 days some enlargement of the adrenals, with widening of the zona glomerulosa, loss of cholesterol and loss of ascorbic acid, the last not significant. Restoration of salt to the diet after 43 days gave rapid recovery to normal in 48 hr.

I. Leitch.

3208

ROSENMAN, R. H., ST. GEORGE, S., FREED, S. C. and SMITH, M. K. **The effect of potassium deficiency upon adrenocortical secretion in the rat.** *J. Clin. Invest.*, 1955, **34,** 1726–1729. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

It has been shown that the low blood pressure and poor response to pressor drugs in rats, which characterise the reaction to a diet lacking K, are relieved by cortisone. To test whether the characteristic response to K deficiency is due to failure of function of the adrenal cortex, adrenal corticosteroids were measured in blood from the adrenal vein in young male rats on a K-deficient diet. The

rates of secretion of 3-keto-Δ^4-steroids, as corticosterone, and of 17:21-dihydroxy-20-ketosteroids, as 17-hydroxycorticosterone, were similar in deprived rats, rats on deficient diet with added KCl and rats on stock diet.—I. Leitch.

DE LA BARREDA, P., ALCALÁ, R. and LÓPEZ FRESCO, J. Sobre algunas constantes de supervivencia en perros adrenoprivos bilaterales. Relación de la composición electrolítica con el peso y la presión arterial. [**Constants of survival in dogs with both adrenals removed. Relation of electrolyte composition to weight and arterial pressure.**] *Rev. clín. española*, 1955, **59**, 13–15. [Inst. Invest. Méd. Clín., Madrid.] English, German and French summaries.

The subjects were 11 dogs with adrenals removed at 2 operations 6 to 10 days apart; they received deoxycorticosterone acetate and cortisone subsequently. Six had a diet of offal and 5 a diet of potato, rice, bones and oil. Variations in weight, arterial pressure and serum electrolytes are presented in a table.

The meat-fed dogs survived for 27 to 44 days; 3 of the others died after 10, 13 and 22 days, the rest survived indefinitely. The dogs on the mixed diet maintained most nearly normal their bodyweight, arterial pressure and serum electrolytes.

BUNGART, H. Untersuchungen an Schilddrüsen von Hirschen aus freier Wildbahn. [**Studies on the thyroids of deer in the wild.**] *Frankfurter Ztschr. Pathol.*, 1955–56, **67**, 13–27. [Pathol. Inst., Duisburg.]

Thyroids were obtained from 88 deer, some in all months of 1954 except September. Activity was estimated in 60 glands which had no sign of post-mortem change; relation between bodyweight and thyroid weight was found for 42 animals.

The histological picture of nearly all the glands examined was typical of the inactive thyroid, with large follicles, flat epithelial cells and basophil colloid. A few glands were moderately active. The absolute weight of the glands ranged from 2 to 13 g. Relative to bodyweight the thyroids were largest in young males, 0·125 g. per kg. bodyweight, and smallest in adult males, 0·104 g. per kg. Values for young and adult females were 0·119 and 0·121 g. per kg. There was little difference in activity with size of the gland. Signs of activity were commoner in thyroids of young and male than in adult and female deer.—D. Duncan.

GOLDSMITH, R. E. and EISELE, M. L. **The effect of iodide on the release of thyroid hormone in hyperthyroidism.** *J. Clin. Endocrinol.*, 1956, **16**, 130–137. [Metabol. Lab., Cincinnati Gen. Hosp., Ohio.]

To 11 patients with hyperthyroidism a tracer dose of 250 μC. ^{131}I was given orally and 72 hr. later synthesis of thyroid hormone was blocked by methylmercaptoimidazole (MMIA) given by mouth, 40 mg. every 8 hr. for 16 to 20 days, divided into 2 periods of 8 to 10 days each. In the second period I was given as NaI, 50 mg. every 12 hr. During both periods γ-ray counts were made twice daily over the thyroid. In 2 instances anterior pituitary thyrotropin was given simultaneously with the NaI in doses of 15 mg. every 12 hr. intramuscularly. Daily counts were plotted against time on semi-logarithmic paper and the slopes of the curves were analysed.

In all the patients the rate of release of hormone was less after NaI was given. When thyrotropin was given with NaI the rate was not slowed down but remained the same as when MMIA was given alone. It is suggested that the slowing effect of iodide on the rate of secretion of thyroid hormone

is probably the result of some interference with thyrotropin activity.—B. W. Simpson.

3215

HIGHLEY, D. R. and PARKER, H. E. **Effects of liver fractions on thyroid function of the rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 638–640. [Dept. Biochem., Purdue Univ., West Lafayette, Ind.]

The 120 rats of both sexes were divided into 2 groups given diets containing 58 and 400 p.p.m. I. These 2 groups were subdivided into groups treated with soluble and insoluble fractions of pork liver, dried pork liver and 0·01 per cent. thiouracil, respectively. The diets were adjusted so that each contained the same amount of protein. Thyroid weight and I content, thyroid protein-bound I (PBI), plasma PBI, B.M.R. and average weekly weight gains were estimated. On the 42nd day of the experiment blood samples were taken, thyroids were excised and PBI was estimated in both.

A goitrogenic substance was found in the liver fraction insoluble in water. In the rats on the diet containing 58 p.p.m. I the insoluble liver fraction produced almost as much goitre as 0·01 per cent. thiouracil. When the diet contained 400 p.p.m. I the goitre was prevented. Dried liver was as effective as water-insoluble liver, but rats given dried liver had very poor growth. The concentration of I in the thyroids of rats given the insoluble liver fraction and low dietary I was about one-third of the normal. This decrease was due to loss of thyroid PBI. When adequate I was present in the diet, not only did thyroid PBI return to normal but plasma PBI values were nearly doubled. Insoluble liver and dried liver increased thyroid size from 7 to 12 mg. per 100 g. bodyweight when I intake was low. There was no difference in thyroid size when I intake was high. Thiouracil increased thyroid size and reduced thyroid I at both levels of I intake. No significant difference of B.M.R. was found in any group.

ANDREWS, E. D. and WHITTEN, L. K. **The effect of phenothiazine on thyroid glands of sheep.** *N.Z. J. Sci. Technol.* [*A*], 1956, **37,** 414–418. [Animal Res. Stat., Dept. Agric., Wallaceville.]

The mean wet weight of thyroids of sheep given 120 g. phenothiazine in 6 doses during 13 weeks was similar to that of untreated sheep. The mean percentage of iodine in glands of phenothiazine-treated sheep was nearly twice that in glands of untreated sheep.—J. C. Gill.

3217

GARREN, L. and GREEP, R. O. **Effects of thyroid hormone and propylthiouracil on eruption rate of upper incisor teeth in rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 652–655. [Harvard Sch. Dent. Med., Boston, Mass.]

Of 23 rats 80 days old, 8 were fed on rat chow containing 0·5 per cent. dried thyroid, 8 on processed chow containing 0·15 per cent. propylthiouracil (PTU) and 7 on ground rat chow. Four rats on PTU were changed to the diet containing thyroid at the end of 5 weeks for 2 weeks. The incisor eruption rate was measured by the method of Schour (*Amer. J. Anat.*, 1932, **50,** 397) once a week.

After 2 weeks on the diet containing thyroid, the growth of incisors was 30 per cent. greater than in the normal rats. Thereafter it declined and was almost normal at the end of 5 weeks. These rats lost weight and 3 died. In the group given PTU, eruption slowed in the second week and in the fourth week reached a minimum of half the normal. After that there was no further decrease. When dried thyroid was substituted for PTU the growth of incisors increased within 1 week by 260 per cent.; this increase was maintained during the next week.

The upper incisors of the rats given PTU had an increased amount of dentine per unit area. The pulp chamber was partly obliterated. The rats given thyroid had incisors with large pulp chambers and a decreased amount of dentine. Since reduced growth of incisors was due to lack of thyroid hormone, its measurement might be of use in demonstrating hormonal activity.—B. W. Simpson.

SHELLABARGER, C. J. **A comparison of triiodothyronine and thyroxine in the chick goiter-prevention test.** *Poultry Sci.*, 1955, **34,** 1437–1440. [Med. Dept., Brookhaven Nat. Lab., Upton, Long Island, N.Y.]

Cockerels were maintained on commercial laboratory chow, and on the 13th day of age were weighed, wing-banded and assigned to experimental groups of the same average weight. In order to enlarge the thyroids, 0·1 per cent. thiouracil was added to the diet. Daily subcutaneous injections of 0·84 or 3·0 μg. triiodothyronine or 3·0 mg. thyroxine or distilled water in the volume of 1 ml. were given from the 14th day. The birds were killed on the 24th day and the thyroids were weighed.

No difference in ability to reduce thyroid size was found between the hormones in chicks, though in rats triiodothyronine reduces the enlarged glands 3 to 4 times as rapidly as thyroxine. This suggests a species difference in response.

DURY, A. **Lipides distribution and phospholipide turnover in tissues of rabbit shortly after growth**

hormone. *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 623–628. [Dorn Lab. Med. Res., Bradford Hosp., Pa.]

Rabbits which had been kept for several weeks on a pellet diet were each given a subcutaneous injection of 5 mg. purified anterior pituitary growth hormone per kg. bodyweight or of physiological saline. Immediately afterwards they were each given 0·5 mC. of ^{32}P-labelled phosphate by intravenous injection. Three hours later a small sample of heart blood was obtained and 6 hr. after the phosphate injection a large sample of heart blood was taken and the animals were killed. Whole liver and aorta were removed for chemical analysis.

All the animals which received growth hormone showed moderately increased liver weight and glycogen and lipid content and increased plasma glucose and lipid values; aorta showed significantly less neutral fat. The ^{32}P studies showed that growth hormone promoted synthesis of phospholipins; aortic phospholipin turnover did not differ from that of the control animals.

LIBBY, D. A., MEITES, J. and SCHAIBLE, P. J. **Growth hormone effects in chickens.** *Poultry Sci.*, 1955, **34**, 1329–1331. [Dept. Poultry Husb., Michigan State Univ., East Lansing.]

Growth hormone, 1 to 2 mg. daily, testosterone, 0·25 to 0·5 mg. daily, and diethylstilboestrol, 0·5 mg. daily, were injected subcutaneously into 4-week-old White Leghorn cockerels for 28 days. Protamone was incorporated into the feed of 2 groups. No hormone had any effect on growth or feed efficiency. Diethylstilboestrol decreased comb size and increased the fat content of the thigh flesh. In 1-week-old chickens growth hormore decreased growth rate and reduced feed efficiency but had no significant effect on weight of comb, liver or spleen or on blood sugar. Injection of growth hormone into the allantoic sacs of 14-day-old embryos had no effect on the bodyweight of newly hatched chickens. These effects are in contrast to those found in some mammals.

3223

BAUM, G. J. and MEYER, R. K. **Influence of diethylstilboestrol on lipids in intact and hypophysectomized cockerels.** *Endocrinology*, 1956, **58**, 338–346. [Dept. Zool., Univ. Wisconsin, Madison.]

Total blood lipids of immature cockerels forcibly fed on a synthetic diet with or without added fat rose after removal of the pituitary, after intramuscular injection of diethylstilboestrol, and further after both treatments. Oestrogen increased the depot fat of intact cockerels on a normal or fat-free diet, but had no effect on the depot fat of hypophysectomised birds. Diethylstilboestrol improved the rate of gain in intact cockerels, but did not affect the efficiency of gain.

PIETERSE, P. J. S. and ANDREWS, F. N. **The estrogenic activity of alfalfa and other feedstuffs.** *J. Animal Sci.*, 1956, **15**, 25–36. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Ovariectomised mice were used for assay of the oestrogenic potency of alfalfa, at different stages of maturity, in 4 successive crops during the spring and summer of 1954. Oestrogenic activity of first growth increased significantly in the early budding stage, declined in early flowering and then increased and remained high until flowering had finished and the plant was in the seed-head stage. In second, third and fourth growth, the pattern of oestrogenic activity differed and the total quantity was much less than in spring growth; in general, there was less oestrogenic activity at the budding stage with a tendency for increased potency with maturity.

All parts of the alfalfa plant possessed oestrogenic activity, but the leaves were more potent than the flowers, and the stems showed least activity.

A wide variety of legumes contained significant amounts of oestrogens, but there was considerable variation among species and among samples within species. By comparison, the oestrogenic activity of grasses, grains and oilseed products was low.

ENERGY EXCHANGE AND SPECIFIC DYNAMIC ACTION

3225

KREBS, H. A. Die Steuerung der Stoffwechselvorgänge. [**The regulation of metabolic processes.**] *Deutsch. med. Wochenschr.*, 1956, **81**, 4–8. [Dept. Biochem., Univ. Oxford.]

The basic unit which determines the rate of a metabolic reaction is the enzyme-substrate system. Maximum rate of reaction rarely occurs in physiological conditions and the limiting factor is usually the quantity of substrate. This is supported by the finding that addition of intermediary products to tissues usually increases the rate of intermediary reactions. Yet there are some reactions which do not depend on the supply of substrate, but on a pacemaker.

Alternative metabolic pathways can result either from the choice of alternative reactions (as in the choice of carbohydrate, fat or protein as source of energy) or from the choice of different directions of the same metabolic path (*e.g.*, synthesis or breakdown of fatty acids). Alternative pathways are never completely independent; for example, oxidation of lactate or triosephosphate or glutamic acid or malic acid or β-hydroxybutyric acid depends on their competition for a common enzyme, pyridine nucleotide (DPN). The one oxidised depends on their relative rates of reaction under the given conditions. Reactions depending on DPN are commonly subordinate to pacemakers. There are two main kinds of pacemaker. One is hormonal. The other is comparable to feedback mechanisms such as thermoregulators controlling gas or electrical supplies to incubators; the heat liberated from the gas produces self-limiting conditions by which the gas is shut off until the limiting conditions are removed. A biological feedback mechanism is the regulation of respiration by CO_2; there are many others. The "purposeful" adaptation of production of energy to physiological needs can be explained to a great extent by the specific character of the enzyme system.

D. Duncan.

3226

MITCHELL, H. H. **The specific dynamic action of food.** *Scientia*, 1955, **49**, June, pp. 7. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

It is difficult and inconvenient to measure specific dynamic action completely since it may continue for many hours, but it may be estimated with sufficient accuracy from intermittent measurements and a sigmoid prediction curve. After similar meals, in the same animal, it differs with the physiological state, *e.g.* growth, lactation, exercise, and the plane of nutrition. The S.D.A. of individual components of diet is not important except for instance in particular contexts such as muscular work, when meat, but not glucose or fat, will raise heat output; or in reference to deficiencies of amino acids and the specific effects of some amino acids. Theories to explain it as due to work of digestion, metabolism of plethora, stimulation of metabolism, *e.g.*, by fatty acids in the ruminant, explain at most only small parts of the whole; that of waste heat in its modern form in relation to such chemical reactions as occur in the tricarboxylic acid cycle appears more acceptable but does not exclude the others, not even the possible participation of endocrine glands, for "it seems inconceivable that they are silent bystanders".—I. Leitch.

ARKHANGEL'SKAYA, N. A. Regulyatziya obmena veshchestv v organizme nedonoshennogo rebenka posle priema pishchi. [**Regulation of metabolism in premature infants after feeding.**] *Fiziol. Zh. SSSR Sechenova*, 1954, **40**, 431–440. [Akad. Med. Nauk SSSR.]

The gaseous metabolism of 20 premature infants was studied in an attempt to find out if there was a difference between the effects of natural and artificial feeding on metabolism. The first feed was not followed by the rise in metabolic rate usual after suckling; this rise was established after 2 to 3 days. When the children were transferred to breast feeding there was a fall in post-prandial metabolic rate at first, and later a rise. It is concluded that a composite reflex is involved in the regulation of metabolism after food has been given to such infants by an artificial method.

DELAGE, J., LE BARS, H., LEROY, A. M. and SIMMONET, H. Influence du repas sur le rythme respiratoire du porc. [**Effect of feeding on respiratory rhythm in the pig.**] *Ann. Zootech.*, 1955, **4**, 173–187. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Five pigs weighing from 30 to 60 kg. were kept in metabolism cages and fed on a standard ration, twice daily. They were always fed by one attendant, who entered the room for that purpose only. The pigs were accustomed to wear a pneumograph.

The respiratory rhythm before feeding was usually more rapid in the afternoon than in the morning, 16·9 and 14·5 respiratory movements per min. for 4 pigs. During a meal the rate increased by about 80 per cent., with a wide individual variation of from 41 to 163 per cent. The increase began when feeding was expected, and all the pigs were especially sensitive to the

smell of the food, which contained fishmeal. As the pigs approached satiety the rate of eating fell, and with it the rate of respiration. The rate of respiration continued to fall more slowly after the meal, but had not reached the pre-prandial level after 1 hr.

In pigs anaesthetised with chloralose and fed by stomach tube the respiratory rate increased by about 20 per cent. and declined only slowly. It is concluded that there are 2 components of the increase in normal pigs, one due to muscular activity and the other caused by the presence of feed in the digestive tract.—D. Duncan.

3229

KAISHIO, Y., HASHIZUME, T., AMBO, S., ABE, G., MASUBUCHI, T., ABE, M., MORIMOTO, H., HORII, S., KURATA, Y., ISHIHARA, M. and TSUCHIYA, H. **[Metabolism of matter and energy in cattle.]** *Bull. Nat. Inst. Agric. Sci., Chiba, Japan* [*G*], 1955, No. 11, 157–226. In Japanese : English summary 227–231.

The respiration chamber was of the open-circuit type, designed for separate collection of urine and faeces. The apparatus is described in detail with diagrams and photographs.

Fasting heat production of 4 black native Japanese cows was measured during four 12-hr. periods at the end of 5 days of fasting, which had been preceded by 7 days of feeding on wild grass hay. The heat production was from 11·2 to 15·1 Cal. per kg. bodyweight daily.

Feeding experiments with 4 bulls and 5 cows were made. The calculated requirements for maintenance were, for bulls and cows, respectively : digestible crude protein 150 and 135 g., total digestible nutrients 1·157 and 1·067 kg. per 100 kg. liveweight.—T. D. Bell.

SCHILLING, J. A., HARVEY, R. B., BECKER, E. L., VELASQUEZ, T., WELLS, G. and BALKE, B. **Work performance at altitude after adaptation in man and dog.** *J. Appl. Physiol.*, 1956, **8**, 381–387. [Dept. Surg., Sch. Aviation Med., Randolph Field, Tex.]

The 3 senior authors were the subjects tested under field conditions at altitudes of 760 and 14,900 ft. above sea level, the latter at Morococha, Peru, where the average pressure was 450 mm. Hg. Under experimental conditions 4 selected and trained dogs were tested in a chamber where the pressure simulated that at 19,000 ft. above sea level. The work was walking at 92 m. per min. on a treadmill ; its severity was increased gradually by a constant and continuous increase in grade. Pulse rate, inspiratory and expiratory volumes, oxygen and CO_2 in expired air, and lactic and pyruvic acids and Hb in blood were estimated and counts of red and white blood cells and measurements of haematocrit were made. There were similar studies with the dogs, which had undergone minor surgical operations to permit measurements of their pulse rates and blood pressure. These measurements were made in the men at the lower altitude, at the higher after acclimatisation for 10 weeks and again at the lower 2 weeks after returning ; in the dogs they were made at 760 ft., at 19,000 ft. and again at 760 ft. after 5 months' acclimatisation to the high altitude. The findings are presented graphically for the individual men and as average values for the dogs.

In the men ventilation rate and ventilatory equivalent, defined as ventilation in litres per litre oxygen consumed, were, for a given load of work, greater at the high than at the low level and there was no associated increase of pulse rate. In the

dogs this change was relatively much smaller than in the men. Oxygen consumption at the 2 levels did not differ greatly in men or in dogs. The characteristic changes in Hb, haematocrit and in red cell volume were seen, and in the men, it took about 4 months for the sea-level values to reappear. The small number of estimations of the blood acids showed that, especially after exercise, the level of lactic acid was lower and that of pyruvic acid higher at the high altitude than at the low.—D. Harvey.

3234

GELINEO, S. and KOCAROV, R. Influence de la température d'adaptation sur l'intensité des échanges respiratoires chez le rat au cours des différentes saisons. [**Effect of adaptation temperature on the intensity of respiratory exchange in the rat at different seasons.**] *C.R. Soc. Biol.*, 1955, **149**, 1652–1654. [Inst. Physiol., Fac. Sci., Univ. Belgrade.]

In experiments with rats it was found that metabolic adaptation to environmental temperature, as estimated from oxygen consumption, required about 15 days. Oxygen consumption was measured at 30°, 10° and 5° C. in rats adapted to different ranges of environmental temperature; the lower the temperature to which they were adapted, the higher the oxygen consumption at all 3 experimental temperatures. In another group of rats placed in January in a temperature of 25° to 28° C. there was no adaptation during the spring months, in fact until June.—D. Duncan.

3235

CASADY, R. B., LEGATES, J. E. and MYERS, R. M. **Correlations between ambient temperatures varying from 60°-95° F. and certain physiological responses in young dairy bulls.** *J. Animal Sci.*, 1956, **15**, 141–152. [N. Carolina State Coll., Raleigh.]

The effect of environmental temperatures from 60° to 95° F., at humidities of 10 and 14·5 mm. Hg, on physiological responses of 4 Holstein bulls was studied when the bulls were 18 and 31 months old. They were kept at each temperature for from 29 to 50 days. Environmental temperature was significantly correlated with rectal temperature, scrotal and rump skin temperatures, respiratory rate and water consumption. Rectal temperature was less closely correlated with other physiological measurements, apart from respiratory rate, which was closely associated with rectal temperature for air temperature between 80° and 90° F.

A delayed response of rectal temperature and respiratory rate to environmental temperature in the second experiment, until the environmental temperature reached 80° F., was thought to be due to improved thermoregulation with advancing age.—T. R. Preston.

3236

YEATES, N. T. M. **Photoperiodicity in cattle. 1. Seasonal changes in coat character and their importance in heat regulation.** *Austral. J. Agric. Res.*, 1955, **6**, 891–902. [Div. Animal Health Proc., C.S.I.R.O., Sir William Macgregor Sch. Physiol., Univ. Queensland.]

In two groups of Shorthorn calves, one subjected to a reversed seasonal trend in length of day and the other to natural daylight, a deep hair coat of winter type was associated with decreasing length of day and a flat glossy coat with increasing length of day. Seasonal temperature differences were without effect on the coat.

Animals exposed to decreasing light which had a deep winter coat, had significantly less heat tolerance, measured by exposing them to a temperature of 105° F. for 3 hr., than animals with a smooth summer coat. Clipping the hair from all animals resulted in both groups having the same heat tolerance, showing that difference in heat tolerance was directly attributable to type of hair coat and not to difference in metabolic state with which hair coat might have been associated.

3237

GELINEO, S. Température d'adaptation et production de chaleur chez les oiseaux de petite taille. [**Adaptation temperature and heat production in small birds.**] *Arch. Sci. physiol.*, 1955, **9**, 225–243. [Inst. Physiol., Fac. Sci., Belgrade.]

The 9 species of birds were pigeon (*Columba domestica*), turtle dove (*Turtur risorius*), linnet (*Acanthis cannabina*), greenfinch (*Chloris chloris*), siskin (*Chrysomitris spinus*), canary (*Serinus canaria*), goldfinch (*Carduelis carduelis*), brambling (*Fringilla montifringilla*) and sparrow (*Passer domesticus*); all but the canary were caught in the Belgrade district. They were tamed to accept the presence of man and accustomed to the metabolism

cage, which is described and illustrated. They were fasted for 12 hr. before experiments.

All the birds adapted their basal heat production in response to changes in environmental temperature. The time required for complete adaptation varied from 1 to 4 weeks [*secondes*, in the summary, is presumably a misprint for *semaines*], according to the species. In the pigeon, adapted B.M.R. at 1° to 3° C. was 1083 Cal. per sq. m. per 24 hr., and at 29° to 32° C., 833 Cal. When the bird was adapted to the lower temperature, polypnoea appeared during exposure at 33·4° C., when heat production was 981 Cal. per sq. m. per 24 hr., but when it was adapted to the higher temperature polypnoea did not appear until the temperature of the respiratory chamber reached 36·7° C., and heat production was 856 to 923 Cal. Values for B.M.R. and thermal neutrality are tabulated for all 9 species when adapted to 3 different environmental temperatures. The greatest increase in metabolism was 85 per cent. in the siskin adapted to cold. Adaptation to cold increased resistance to cold in all species: maximum metabolism occurred at a lower temperature and body temperature was maintained better. A canary and a goldfinch when adapted to warm environment died in cold less extreme than they had survived when adapted to cold. It is concluded that seasonal changes in temperature, even when they are as extreme as in the Belgrade area, are gradual enough to allow adaptation.—D. Duncan.

CARBOHYDRATES

3238

PINES, K. L. **Carbohydrate metabolism.** *Med. Clins. N. Amer.*, 1955, **39**, 831–844. [Dept. Med., Coll. Phys. Surg., Columbia Univ., New York.]

3239

FORSYTH, B. T. and PLOUGH, I. C. **The protein-sparing effect of carbohydrate with and without testosterone.** *J. Lab. Clin. Med.*, 1955, **46**, 840–847. [Dept. Metabol., Med. Div., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

The 3 volunteer subjects were a 58-year-old man with alcoholic cirrhosis of the liver, a man of 24 with Reiter's syndrome in remission and a man of 23 with rheumatoid spondylitis. All were ambulatory during experiments. The first 2 had a solid basal diet, the third a liquid diet; their protein intakes were stable at 0·7, 1·1 and 1·5 g. per kg. bodyweight daily, respectively.

The patient on the lowest N intake was in positive N balance for the whole 36 days of experiment; testosterone propionate increased N retention slightly, increased carbohydrate intake increased it considerably and the effect persisted for the whole 18 days of supplementation. Similar effects were found in the other 2 patients, who had 1 and 2 negative balances, respectively, on the basal diet, slight improvements with testosterone and greater and persistent improvement, for 15 and 16 days, with increased carbohydrate intake. The extra carbohydrate was given 2 to 4 hr. after meals. The N-sparing effect varied from 1·0 to 1·7 mg. N per added calorie. Testosterone was not effective during carbohydrate supplementation.

D. Duncan.

3240

DUNCAN, L. J. P. **The intravenous glucose tolerance test.** *Quart. J. Exp. Physiol.*, 1956, **41**, 85–96. [Dept. Therap., Univ. Edinburgh.]

Two intravenous sugar tolerance tests were made, between 5 and 14 days apart, in 28 normal adults and 21 patients with mild diabetes mellitus which allowed withdrawal of insulin for 48 hr. before tests. All the subjects had a diet containing at least 250 g. carbohydrate daily for 4 days and were fasted for 15 hr. before tests. The blood sugar values obtained during the tests were used to compare 2 indices of glucose tolerance.

The " total index " was obtained by the method of Bastenie *et al.* [The reference should read Conard *et al.*; see Abst. 4539, Vol. 23], who called it the coefficient of carbohydrate assimilation. The " increment index " was that of Amatuzio *et al.* (*J. Clin. Invest.*, 1953, **32**, 428) [the names of the authors are without exception wrongly spelt]. Both indices were found to be reproducible in the same subject. It is deduced that the rate of removal of blood glucose is more nearly proportional to the excess above fasting concentration than to the total concentration, and that the " increment index " is the more reliable of the two tested.—D. Duncan.

3241

POLITZER, W. M. **Glucose-tolerance test: a comparison of results in the African and European.** *S. African J. Lab. Clin. Med.*, 1955, **1**, 270–272. [S. African Inst. Med. Res., Johannesburg.]

Sugar tolerance tests with 50 g. glucose were made on 2 groups each of 42 patients in hospital with disorders known not to affect carbohydrate

metabolism. The Africans were 18 men and 24 women aged from 14 to 59 years and the Europeans 19 men and 23 women aged from 20 to 55 years. Average values for glucose during fasting and at 30-min. intervals were for Africans 75, 98, 106, 97 and 85, and for Europeans 84, 126, 131, 114 and 92 mg. per 100 ml. blood as estimated by the method of King and Garner (*J. Clin. Pathol.*, 1947–48, **1**, 30). The differences were statistically significant, and endocrine activity is proposed for further study in the search for an explanation.

D. Harvey.

TEST, C. E., NICHOLS, R. L., LANDAU, R. L., RICKETTS, H. T. and LOUGHEAD, R. **A study of the "flat" oral glucose tolerance curve and its relation to rate of emptying of the stomach.** *Amer. J. Med. Sci.*, 1956, **231**, 69–74. [Dept. Med., Indiana Univ. Sch. Med., Indianopolis.] Interlingua summary.

Of 26 patients in whom the rise in a sugar tolerance curve had not exceeded 30 mg., 10 gave a normal response when re-examined and were discarded. More detailed tests were made on the others, but findings in relation to time of emptying of stomach were inconsistent. Seven of the 16 showed flat curves for venous and rather low peaks for capillary blood and in 5 of these the fall of inorganic P in serum was less than 15 per cent. of the fasting value. From the findings for that group retardation of absorption from the intestine is thought to be the most likely explanation of the phenomenon.

In the end 15 of the original 26 patients showed normal responses.—D. Harvey.

3243

KRITZER, M. D., SHRIFTER, N. and DEMETRIOU, J. A. **Carbohydrate metabolism. 1. A study of changes in serum inorganic phosphorus during glucose-tolerance test in normals, diabetics, and prediabetic women.** *Arch. Int. Med.*, 1956, **97**, 62–67. [Dept. Med., Univ. S. California Sch. Med., Los Angeles.]

The pre-diabetics were 30 women with normal glucose tolerance who had given birth to large babies. The diabetics were 16 diabetic mothers whose glucose tolerance had been normal 3 years previously at the birth of their babies and 13 elderly subjects with long-standing mild diabetes. Serum inorganic P levels were estimated during oral glucose tolerance tests in these subjects and in normal young women.

Values in pre-diabetics differed little from normal. Those in diabetes of long standing were consistently above normal and those in recent diabetes were consistently below normal. Serum inorganic P levels were estimated also during intravenous glucose tolerance tests in normal subjects and in patients with diabetes of long standing. A greater and earlier drop in P level occurred in normal subjects than in the diabetics. It was not found in normal subjects given glucose by mouth.

The results are discussed in relation to the role of the liver in P metabolism.—F. C. Aitken.

TAGNON, R. F. and DEVREUX, S. **Effect of intravenous injection of fructose, with and without ACTH administration, on the level of blood glucose.** *J. Clin. Endocrinol.*, 1955, **15**, 1475–1481. [Lab. Exp. Med., Univ. Brussels.]

3245

BUNDING, I. M., DAVENPORT, M. E. (Jr.) and SCHOOLEY, M. A. **The glucose tolerance test in swine and its implications.** *J. Animal Sci.*, 1956, **15**, 234–241. [Armour Labs., Vet. Res. Dept., Chicago, Ill.]

Oral glucose tolerance tests were made on pigs of mixed breed, including mature lactating sows and growing pigs. The animals were fasted for 16 to 24 hr. before tests and the dose of glucose was 0·5 or 1 g. per lb. bodyweight. Blood samples were taken before and ½, 1, 2 and 3 hr. after the glucose was given.

There were large differences in glucose tolerance even between littermate pigs on the same ration. Of 6 littermate barrows (castrated males) the 3 with good tolerance were all heavier than the 3 with poor tolerance. Of 24 pigs tested, 3 had curves of diabetic type; 2 of these were lactating sows. Two pigs stunted as a result of past hog cholera infection had poorer tolerance than their well grown normal littermates.—D. Duncan.

SHULL, K. H. and MAYER, J. (with SILIDES, D. J.) **Analysis of the blood sugar response of obese-hyperglycemic mice and normal mice to hormones: insulin, glucagon, and epinephrine.** *Endocrinology*, 1956, **58**, 220–225. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

The fall in fasting blood sugar 2½ hr. after obese and non-obese mice were given 20 units insulin per kg. bodyweight was similar, 130 and 117 mg. per 100 ml. blood, but in the non-obese the fall caused convulsions and death. If fasting began 24 hr. before insulin was given the reductions were again similar, 61 and 54 mg., respectively. In the obese mice the level of 31 mg. was reached without convulsions and they recovered without food. They survived also if the fasting was continued and treatment repeated 24 hr. later.

In similar experiments 25 μg. glucagon or adrenaline was given intraperitoneally and the

change after 30 min. was studied. In obese mice the increases were 79 and 149 mg., but if the animals had fasted for 12 hr. before treatment the changes were greater, 197 and 249 mg. per 100 ml. blood, respectively. In tests with glucagon alone on animals on a carbohydrate-free diet (see Abst. 3353, Vol. 24) the increase was 85 mg., comparable with that in obese mice on a normal diet. In non-obese animals the increases with glucagon and adrenaline were 44 and 189 mg. without fasting and 7 and 119 mg., respectively, with fasting for 12 hr. before treatment.—D. Harvey.

SHREEVE, W. W., BAKER, N., MILLER, M., SHIPLEY, R. A., INCEFY, G. E. and CRAIG, J. W. **C^{14} studies in carbohydrate metabolism. 2. The oxidation of glucose in diabetic human subjects.** *Metabolism*, 1956, **5,** 22–34. [Radioisotope Unit, Veterans Admin. Hosp., Cleveland Ohio.]

For part 1 see Abst. 3764, Vol. 25.

2. Eight diabetic subjects from whom insulin was withdrawn and 4 normal subjects were injected with radio-active glucose after fasting for about 16 hr. Of 5 stable diabetics, 2, who were deprived of insulin for 65 and 120 hr. from the last dose to the injection of glucose compared with 15 to 27 hr. for all the other diabetics, developed moderate ketosis and along with 3 labile diabetics with severe ketosis produced less than normal amounts of $^{14}CO_2$. The rate of oxidation of glucose in g. per kg. per hr. was below normal in one of the stable diabetics with ketosis and in 2 of the labile subjects. The percentage contribution of glucose to CO_2 during the 6 hr. of study changed little in normal or diabetic subjects.

The glucose pool in normal subjects, stable diabetics and labile diabetics was calculated as 24, 26 and 30 per cent. of bodyweight. The mean rate of total glucose turnover was 0·085, 0·10 and 0·19 g. per kg. per hr. and the rate constant 0·69, 0·19 and 0·30 per cent. per min.

A. Hepburn.

HAUSBERGER, F. X. and HAUSBERGER, B. C. **Overall glucose utilization in steroid diabetic guinea pigs.** *Amer. J. Physiol.*, 1955, **183,** 302–306. [Daniel Baugh Inst. Anat., Jefferson Med. Coll., Philadelphia, Pa.]

Utilisation of glucose by adult male guinea-pigs was estimated during a pre-experimental period when the animals received to appetite weighed amounts of Purina rabbit checkers and 50 g. lettuce daily and during an experimental period when steroid diabetes had been produced by subcutaneous injection of cortisone or hydrocortisone. The amount of glucose utilised was calculated from the carbohydrate content of the food, from the gluconeogenesis from protein with a D : N ratio of 3·65 and from the amount of glucose in the urine. It was assumed that all the N.P.N. in urine represented protein utilised for gluconeogenesis equally in both control and experimental periods.

All the guineapigs injected with steroids and maintained in a healthy condition fully compensated for the loss of glucose by increased food intake and increased gluconeogenesis. The amount of glucose utilised by the diabetic guinea-pigs was not diminished.—G. F. Garton.

3251

PATTERSON, J. W. **Effect of a high fat fructose and casein diet on diabetic cataracts.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 706–708. [Dept. Anat., Sch. Med., Western Reserve Univ., Cleveland, Ohio.]

Two groups, each of 10 male rats rendered diabetic by intravenous injection of 40 mg. alloxan monohydrate per kg. bodyweight, with blood sugar levels consistently above 350 mg. per 100 ml., were given, respectively, a diet of unlimited amounts of water and ground dog chow and a diet of 50 per cent. fructose, 25 per cent. maize oil and 25 per cent. casein. Blood sugar was estimated at least once a week and the eyes of the rats were examined daily for cataract. On the fructose, fat and casein diet the blood sugar remained high, but cataracts were prevented and growth was accelerated.—G. F. Garton.

NATH, M. C. and BHATTATHIRY, E. P. M. **Prevention of alloxan diabetes by a condensation product of glucose and acetoacetate. 2.** *Metabolism*, 1956, **5,** 3–10 ; 11–17. [Dept. Biochem., Univ. Nagpur, India.]

See also Abst. 3092.

1. In rats, glucose followed immediately by acetoacetate or the sodium salt of their condensation product, 2-tetrahydroxybutyl-5-methyl-4-carbethoxyfuran, prevented both diabetes and the decrease of reduced glutathione in the blood when injected 45 min. before alloxan. Acetoacetate alone increased sugar and caused a lower level of reduced glutathione in the blood. In experiments with rabbits, acetone, β-hydroxybutyric acid or acetate could not replace acetoacetate when they were injected with glucose.

2. The condensation product prevented alloxan diabetes in 50 per cent. of rabbits when injected 5 min. before alloxan in the molecular proportion of 0·5 : 1. Protection increased as the ratio increased, to reach 75 per cent. at a ratio of 2 : 1. Blood urea and plasma alkaline phosphatase, which increase in alloxan diabetes, remained normal.

1 : 2-Dienolglucose, which occurs in normal blood and was produced by hydrolysis of the condensation product or by incubation of glucose at *p*H 7·2 and 30° C., combined with alloxan *in vitro*, perhaps to give alloxanic acid, a compound which does not produce diabetes.—A. Hepburn.

3253

Gómez F. de la Cruz, A. Estudio de los fenomenos hipoglucemicos en resecados gastricos. [**Hypoglycaemic phenomena after gastric resection.**] *Rev. clín. española*, 1954, **52**, 323–331. [Málaga.] English, German and French summaries.

Ten ml. ether instilled into the duodenum or the proximal part of the jejunum in human subjects produced a fall in the blood sugar ; the effect was greater from the jejunum. The tube alone produced a similar but much smaller effect. Of 423 subjects with partial resection of the stomach, mostly the Billroth II operation, 22 had hypoglycaemic symptoms afterwards. These began between 15 and 30 days after operation in 19 subjects and from 3 to 5 months later in the other 3. The blood sugar curves in response to glucose were normal in 19, diabetic in 2 and diabetoid in 1. Ether always brought about a fall in blood sugar, which was especially profound in 6 ; these 6 also showed small falls in response to the tube alone or to HCl. Free HCl was present in gastric secretion from 20 of the 22 patients and was secreted in response to histamine in the others.

It is suggested that the fall in blood sugar is a response to stimulation of nerves in the intestine by mechanical or chemical stimuli. It differs from the dumping syndrome.—D. Duncan.

3254

Koulischer, N. and Pickering, D. E. (with Cole, M.) **Glycogen-storage disease. A study on the effect of sodium *l*-thyroxine and glucagon.** *Amer. J. Dis. Child.*, 1956, **91**, 103–112. [Dept. Paediat., Univ. California Med. Centre, San Francisco.]

Reports are presented of 3 infants with von Gierke's disease treated with high-protein, galactose-free diet and *l*-thyroxine daily. All improved. When sodium-*l*-thyroxine was given for 6 weeks there was a significant loss of non-fermentable reducing substances in blood and reduced insulin sensitivity. In von Gierke's disease response to glucagon was below normal. When glucagon was given daily during the seventh week of *l*-thyroxine administration the blood sugar response to a single dose of glucagon was greater at the end of the week than at the beginning. Such an effect on glucagon tolerance was not found when glucagon was given for 1 week before the beginning of treatment with *l*-thyroxine.—F. C. Aitken.

3255

Adcock, L. H. and Gray, C. H. **Metabolism of sorbitol.** *Nature*, 1956, **177**, 329–330. [Dept. Chem. Pathol., King's Coll. Hosp. Med. Sch., London, S.E.5.]

Two subjects, one normal and one diabetic, were given, by mouth, 35 g. sorbitol uniformly labelled with ^{14}C and with total activity 30 μC. Within 1 hr. expired CO_2 was highly radio-active and it remained so for more than 8 hr. It is suggested that as much as 90 per cent. of the activity appeared in that form ; only about 10 per cent. was in urine and faeces.—D. Harvey.

3256

Fournier, P. Action de cellobiose et de la glucosamine, composés typiquement structuraux, sur l'utilisation du calcium. [**Action of cellobiose and glucosamine, typical structural compounds, on calcium utilisation.**] *C.R. Acad. Sci.*, 1956, **242**, 674–676.

The effect on the coefficient of utilisation of Ca of carbohydrates was studied as described earlier (Abst. 745, Vol. 25). Maltose, lactose or cellobiose formed 12 per cent. of the diet or glucosamine 6 per cent. The coefficients of utilisation of Ca with these 4 substances were 19·9, 33·5, 32·7 and 50·2 per cent. Cellobiose thus behaved as a typical structural carbohydrate, but glucosamine was remarkable for its large effect. Glucosamine was found to favour the accumulation of organic matter in the long bones, and the suggestion is made that it may enter into the formation of cartilage.

LONGLEY, R. W., SHIRKEY, A. L., ALVIG, O. H. and ROE, J. H. **Rate of glycogenesis in the liver of the rat after parenteral administration of glucose, fructose and invert sugar.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90**, 510–511. [Dept. Biochem., Sch. Med., George Washington Univ., Washington, D.C.]

The rates of formation of glycogen in rat liver after intraperitoneal injections of fructose, sucrose or glucose decreased in that order. The rate during the first 3 hr. was about twice as high with fructose as with glucose.—A. Hepburn.

3259

WINTERNITZ, W. W. and LATTANZI, W. E. **Liver glycogen reserves in experimental diabetic ketosis.** *Endocrinology*, 1956, **58**, 232–234. [Dept. Physiol., Sch. Med., Yale Univ., New Haven, Conn.]

Male rats weighing 180 to 240 g. and fed on Purina chow were made diabetic by intravenous injection of alloxan. They were killed from 10 days to 3 months later, some after they had fasted for 24 hr.

In 7 fed and 8 fasted normal rats, respectively, liver glycogen was 6·49 and 0·12 per cent. Corresponding values for 11 and 17 diabetic rats were 1·81 and 2·16. Blood sugar values for the 4 groups in the same order were 100, 78, 401 and 177 mg. per 100 ml., and blood ketones 1·19, 7·96, 17·4 and 8·08 mg. per 100 ml. The high blood ketone values of the diabetic rats were thus not dependent on depletion of liver glycogen.—D. Duncan.

Liver glycogen fractions which could be distinguished by the ultracentrifuge (Abst. 657, Vol. 26) could not be separated electrophoretically. There were qualitative differences in the iodine colours of the fractions.—H. G. Bray.

3261

SHULL, K. H. and MAYER, J. **The turnover of liver glycogen in obese hyperglycemic mice.** *J. Biol. Chem.*, 1956, **218**, 885–896. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

Naturally obese hyperglycaemic mice had the same percentage of glycogen in the liver as their normal littermates, but had twice as much total glycogen because their livers were larger. Mice made obese with gold thioglucose had enlarged livers and more total glycogen. The obese mice had significantly greater amounts of glycogen in leg muscles than the normal mice. The turnover of liver glycogen, measured by the incorporation of glucose uniformly labelled with ^{14}C, was about 6 times as rapid for total glycogen and 3 times as great per g. liver and per mg. glycogen in the obese as in the normal mice.—A. Hepburn.

3262

MORRISON, A. B. **The effect of dextran on serum proteins and serum cholesterol.** *Quart. J. Exp. Physiol.*, 1956, **41**, 51–57. [Med. Res. Counc. Dept. Exp. Med., Univ. Cambridge.]

Ten ml. of blood was withdrawn from the saphenous vein of 4 dogs after they had fasted all night. Each animal was then given 20 ml. per kg. bodyweight of a 10 per cent. salt-free solution of dextran in 5 per cent. dextrose. From 3 dogs a sample of blood was withdrawn 6 hr. after the infusion; the next morning a sample of blood was withdrawn from the saphenous vein of each. In similar experiments on 10 rats 1 ml. blood was obtained from the tail vein in the morning. The animals were then lightly anaesthetised, the femoral vein was exposed and 3 ml. of the 10 per cent. salt-free dextran in 5 per cent. dextrose was injected. The following day the rats were again anaesthetised and blood was withdrawn from the aorta while the heart was still beating. The Hb value, haematocrit and cholesterol content of each sample were estimated and electrophoretic studies of the proteins were made. In the samples from the dogs the serum proteins were estimated chemically.

In the dogs Hb and haematocrit were well below their initial values 6 hr. after the infusion but returned to "normal" after 24 hr. Serum cholesterol and total protein remained lower than they were initially; electrophoretic studies confirmed that there was a fall in serum globulin. Results in the rats were similar to those in the dogs; when the changes in the red blood cell constituents due to the dilution had disappeared there remained a decrease in serum globulin and serum cholesterol.—G. F. Garton.

DAUM, K., TUTTLE, W. W., GUGEDAHL, A., ROBERTS, H. and SALZANO, J. **Nitrogen, calcium and phosphorus utilization by 12- to 14-year-old boys.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 36–38. [Dept. Nutrit., State Univ. Iowa, Iowa City.]

During an experiment on the effects of altered breakfast habits on the physiological responses of boys aged 12 to 14 years (Abst. 5169, Vol. 25) data were collected at intervals from 6 members of the groups on utilisation of N, Ca and P.

The mean N, Ca and P balances were positive during all the periods with breakfast. Two subjects had a negative N balance during the period of no breakfast and one subject had a negative P balance during the cereal and milk period. Ca and P were utilised at about the same levels in all 3 periods. Mean N retention was significantly greater with the cereal and milk breakfast than with no breakfast. There was no significant difference in N retention between the periods with cereal and milk and with bacon, egg and milk breakfasts. The height changes which occurred during the study were within the predicted range for the age group studied. The weight changes were erratic; 2 subjects were above and one in the predicted weight range. One subject, who was on a restricted diet because of his tendency toward overweight, did not gain.

PHANSALKAR, S. V. and PATWARDHAN, V. N. **Utilization of animal and vegetable proteins. Nitrogen balances at marginal protein intakes and the determination of minimum protein requirements for maintenance in young Indian men.** *Indian J. Med. Res.*, 1956, **44,** 1–10. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Patwardhan *et al.* (Absts. 601, 5353, Vol. 20) found that Indian adults excreted more N in the urine when vegetable protein in the diet was replaced by animal protein, contrary to the findings of Murlin *et al.* (Absts. 3402, 3403, 3405, Vol. 8) with American adults on a lower intake of protein. To clear up the discrepancy, 4-day balance experiments were made with 5 healthy Indian men aged from 21 to 27 years, on diets comparable to those of Murlin *et al.*, supplying about 40 g. protein and 3250 Cal. daily. Nearly 80 per cent. of the protein was supplied by (1) eggs, (2) a mixture of rice, pulses and whole wheat flour, or (3) wheat flour of 70 per cent. extraction. Details are given of the other foods and proximate composition of the diets and of the methods of collecting and analysing samples of urine and faeces.

When egg protein was replaced by protein from cereals and pulses, urinary N fell and faecal N rose but positive N balances were maintained, except in 1 subject who was losing N on the egg diet; but when egg protein was replaced by wheat protein, urinary N rose and N balances declined or became negative, in agreement with the results of Murlin *et al.* The average biological value and egg replacement value, calculated by the methods of Murlin *et al.*, were: cereals and pulses, 111, 103; wheat alone, 86, 88. The values for wheat agree well with those of Murlin *et al.* The results are additional evidence for the value of pulses in conjunction with cereals. The discrepancy referred to at the outset is explainable by the fact that Murlin *et al.* used a single cereal and Patwardhan *et al.* a mixture of cereals and pulses.

The literature on N requirement is discussed. The subjects of Murlin *et al.* were in N equilibrium at an intake of 73 to 80 mg. N per kg. bodyweight and 3·2 to 3·8 g. N per sq. m. body surface; the Indians, who were lighter, on 88 to 150 mg. per kg. bodyweight and 3·6 to 4·5 g. per sq. m. body surface. The results for the first 2 diets yielded the equation

$$y = 0{\cdot}4047x - 1{\cdot}4365,$$

where y = N balance and x = N intake, both in g. per sq. m. body surface. From this it was deduced that for N equilibrium 3·55 g. N per sq. m. body surface is required daily, equivalent to 38·2 g. protein from cereals and pulses for an adult of 5 ft. 6 in. and 70 kg., in fairly close agreement with the results of Hegsted *et al.* (Abst. 3303, Vol. 16) for a vegetable protein diet. For wheat 46 g. is tentatively suggested.—W. M. Deans.

REISS, E., PEARSON, E. and ARTZ, C. P. (with BALIKOV, B.) **The metabolic response to burns.** *J. Clin. Invest.*, 1956, **35,** 62–77. [Surg. Res. Unit, Brooke Army Med. Centre, Fort Sam Houston, Tex.]

Balances of N, K, P, Ca, Mg, Na and Cl were measured in 4 men and 1 woman who had burns covering from 25 to 70 per cent. of body surface and of second or third degree. They were given in rotation one of 3 basal diets supplying daily about 2000 Cal., to which was added a mixture of eggs, dried milk and Dextri-Maltose. If the full amounts were taken the patient received about 4700 Cal. and 200 g. protein. Full descriptions are given of the patients' conditions and of the methods of study; charts are reproduced to show the mean daily balances, generally for 10-day periods, during treatment, which lasted in all for between 60 and 180 days.

In the catabolic phase N balance was negative for 28, 36, 31, 30 and 15 days in the different subjects, mainly because of large amounts in urine. With 1 g. N taken as equivalent to 30 g. tissue the patients lost between 8·2 and 11·7 kg. lean body tissue in the catabolic phase. Changes in fat stores were taken as the difference between actual change of weight and the change of lean tissue calculated from the N balance; they were substantial in both catabolic and anabolic phases. In the catabolic phase K balance was variable but generally negative. Ca and P balances were difficult to interpret and changes in Mg balance were parallel to the amounts excreted in faeces. A consistent finding was that, in the early stages, the negative N balance could not be related to the balances of K and P; there may have been destruction of tissue relatively rich in N or retention of K and P in intracellular fluid or with glycogen.

Strickler, J. H., Rice, C. O. and Treloar, A. E. **Observations on the relationship of output to intake for total fluids, nitrogen, potassium, sodium, and chloride for perisurgery patients under parenteral nutrition.** *Surgery*, 1956, **39**, 152–160. [Med. Sch., Univ. Minnesota, Minneapolis.]

From an assessment of balance observations collected from 102 adult surgical patients on complete parenteral nutrition for an average of 5 days each, yielding 488 "patient days" for estimation in each of the items under study, it was found that the average patient requires 2·75 litre fluid, 18 g. N, 70 m. equiv. K, 90 m. equiv. Na and 90 m. equiv. chloride every 24 hr. to balance output and thus maintain equilibrium. It is emphasised that each individual must be considered, as many vary greatly from the average.

G. F. Garton.

3269

Schwartz, M. K., Bodansky, O. and Randall, H. T. **Metabolism in surgical patients. 1. Nitrogen metabolism in totally gastrectomized patients. 2. Fat and mineral metabolism in totally gastrectomized patients.** *Amer. J. Clin. Nutrit.*, 1956, **4**, 45–50; 51–60. [Surg. Metabol. Sect., Div. Exp. Surg., Sloan-Kettering Inst., New York.]

1. Seven patients who had had total gastrectomy 4 months to 5 years previously and who were free of recurrent disease at the time of study were given controlled intakes of identical diets during 15 three-day metabolic periods and N excretion was measured. Faecal N was significantly related to N intake. The amount of dietary N necessary to prevent negative N balance was significantly greater in the gastrectomised patients than in normal persons.

2. In the same patients and 2 others fat, Ca, P, Mg and K were estimated in faeces and urine excreted during each metabolic period. Eight of the 9 patients excreted abnormally large amounts of faecal fat. The regression line representing the relation between fat intake and excretion was significantly different from that in normal persons. The average excretion of faecal fat, 20·2 per cent. of the intake, was significantly higher than that calculated from normal persons. The metabolism of Ca, P, Mg and K, as represented by the regression equations relating total excretion to total intake, did not differ in the gastrectomised patients from those in normal persons.—G. F. Garton.

Harris, R., Norman, A. P. and Payne, W. W. **The effect of pancreatin therapy on fat absorption and nitrogen retention in children with fibrocystic disease of the pancreas.** *Arch. Dis. Childhood*, 1955, **30**, 424–427. [Hosp. Sick Child., Gt. Ormond St., London.]

In 12 children treatment with 5 g. pancreatin 4 times a day increased mean fat absorption from 46 to 67 per cent. and mean N balance from − 3·75 to + 1·61 g. Larger amounts of pancreatin, 15 g. 4 times a day, slightly increased fat absorption, to 71 per cent., and substantially increased N retention, to 10·77 g. This last increase was attributed to the N of the pancreatin; the 60 g. daily increased average daily protein intake by about 25 per cent. Children gained weight when given the higher level of pancreatin. The lower level is probably sufficient for enzyme activity.—F. C. Aitken.

Crispell, K. R., Parson, W. and Hollifield, G. (with Brent, S.) **A study of the rate of protein synthesis before and during the administration of l-triiodothyronine to patients with myxedema and healthy volunteers using N-15 glycine.** *J. Clin. Invest.*, 1956, **35**, 164–169. [Dept. Int. Med., Sch. Med., Univ. Virginia, Charlottesville.]

The rate of protein synthesis in 6 patients with primary myxoedema, as measured with ^{15}N-glycine (see Abst. 4569, Vol. 23), was below the range found for 5 healthy volunteers. Five were in slight to moderate positive N balance. The administration of triiodothyronine to 4 of the patients for up to 10 days produced a negative N balance with no consistent change in the rate of protein synthesis. Continued administration in 2 of them restored the N balance and increased the rate of protein synthesis, in one to a normal level. Triidothyronine decreased the rate of protein synthesis in a normal subject and gave a slightly negative N balance.—A. Hepburn.

Heinicke, H. R., Harper, A. E. and Elvehjem, C. A. **Protein and amino acid requirements of the guinea pig. 1. Effect of carbohydrate, protein level and amino acid supplementation.** *J. Nutrition,* 1955, **57,** 483–496. [Dept. Biochem., Univ. Wisconsin, Madison.]

Groups of 5 guineapigs were adapted to mixtures of the experimental diets with 20 per cent. alfalfa meal. One group then received the basal diet of sucrose or dextrin 78, casein 10, maize oil 4, salts 4, potassium acetate 2·5, MgO 0·5, choline chloride 0·35, DL-methionine 0·3, vitamin mixture 0·25 and DL-tryptophan 0·1 per cent. with 18 per cent. roughage in the form of Solka-Floc ; fresh water with added vitamin C was given once or twice daily. For other groups casein or amino acids were added at the expense of carbohydrate. Originally it was intended to measure growth when graded levels of casein, 10 to 30 per cent., were given for 4 weeks, after which the livers would be analysed for fat, but the 10 and 15 per cent. casein groups were discontinued after 2 weeks.

After 4 weeks supplements of urea and amino acid were tried with the 20 and 25 per cent. casein groups, respectively. The 6 groups receiving either sucrose or dextrin and 20, 25 and 30 per cent. casein were used to study the effect of supplements of amino acids in experiments which lasted 4 to 8 days.

No definite protein-sparing action was found with dextrin, and differences between the sucrose and dextrin diets were usually slight. In general, the responses to combined amino acid supplements were slightly greater with sucrose diets, but in a few instances dextrin appeared more effective. The amino acid in shortest supply in casein was arginine, apparently because the guineapig has a high arginine requirement and because of the relatively low level and limited availability of arginine in casein. With supplements of arginine, methionine was limiting in the 25 per cent. casein and sucrose diets and both tryptophan and methionine were limiting in the 20 per cent. casein and sucrose diets. The guineapig was shown to be extremely sensitive to changes in the diet, such as the omission of an essential item or the addition of a component in excess.—G. F. Garton.

Donovan, G. A. and Balloun, S. L. **Effect of dietary protein and energy on chick liver fat accumulation.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 692–694. [Dept. Poultry Husb., Iowa State Coll., Ames.]

Groups of 10-day-old chicks, which had been maintained on a complete basal diet, were fed to appetite for 10 days on 10 different diets which varied in protein content from 14 to 30 per cent. ; 5 diets were of low energy value, 720 Cal. productive energy per lb., and 5 of high energy value, 1055 Cal. per lb.

There was an inverse relation between the amounts of dietary protein and of liver fat ; the energy value of the diet did not appear to influence liver fat.—G. A. Garton.

Mellinkoff, S. M., Frankland, M., Boyle, D. and Greipel, M. **Relationship between serum amino acid concentration and fluctuations in appetite.** *J. Appl. Physiol.*, 1956, **8,** 535–538. [Dept. Med., Sch. Med., Univ. California, Los Angeles.]

Serum amino acid and blood sugar were estimated in normal volunteers and patients without disease affecting carbohydrate or protein metabolism at intervals after a breakfast with 20 g. protein, infusions of hydrolysed casein with or without glucose, or ingestion of hydrolysed casein.

Experiments were with from 9 to 13 subjects. When each blood sample was taken the subject was asked whether he was hungry. The serum amino acid concentration was reciprocally related to the crude assessment of the state of appetite in all experiments. The blood sugar was similarly related to appetite after infusions of glucose and hydrolysed casein, but casein alone, infused or ingested, caused both blood sugar and appetite to decrease.—A. Hepburn.

IMPERATO, C., LO BIANCO, S. and SALA, I. Comportamento nel lattante sano e nell'immaturo della curva aminoacidemica e dell'aminoaciduria dopo carico orale di aminoacidi. [**Concentration of amino acids in the blood and urine of healthy and premature infants after oral administration of amino acids.**] *Lattante*, 1955, **26,** 489–503. [Ist. Clin. Pediat., Univ. Parma.] English summary.

Amino-acid N was estimated by Folin's method in the blood of 4 premature and 15 term babies, before and after oral administration of 1 g. per kg. bodyweight of a protein hydrolysate (Nesmida Nestlé). Amino acids were estimated in the urine by paper chromatography before administration of the hydrolysate and for 6 hr. afterwards. The same estimations were made on 3 of the babies given a milk meal with and without the hydrolysate.

The mean value of α-amino N in the blood in mg. per cent. for babies from 1 to 2 months old was 7·6, but for premature infants it was 11·5. After administration of the hydrolysate the peak value was reached within from 30 to 60 min. in premature infants. In term infants the response was much more variable ; some showed little rise, if any.

In the urine response varied greatly in different individuals. In some there was increase in the amount of amino acids, and amino acids not present before appeared in the urine, but in others, and particularly in the premature infants, there was very little change.

After a milk meal the blood value rose somewhat, and after a milk meal with hydrolysate the curve of response was only slightly higher than that with hydrolysate alone. In the urine there was little change after the milk meal, but some increase when the hydrolysate was given as well.—E. M. Hume.

HEIM, L. and KAFFANKE, V. Die funktionsdiagnostische Bedeutung fortlaufender Aminosäurenbestimmungen in Blut und Urin bei kindlicher Hepatitis. [**Importance for the estimation of (liver) function of repeated estimation of amino acids in blood and urine of children with hepatitis.**] *Ann. paediat.*, 1955, **185,** 348–361. [Kinderklin., Univ. Würzburg.] English and French summaries.

The subjects were 19 children from 3 to 13 years old with jaundice, usually due to epidemic hepatitis ; for 10 to 14 days during treatment total amino N was estimated daily in 24-hr. urine and the amino acids were separated by paper chromatography. Serum bilirubin was estimated also.

There was a strong positive correlation between the total output of amino N and the degree of icterus. In one child with haemolytic icterus there was no such relation, and the amino N output remained within normal limits. Serum amino N remained normal in all the children. Alanine and glycine were found in all chromatograms of urine and taurine in most. Glutamic acid, serine and valine were often present, leucine, methionine, proline, threonine and aspartic acid only in the more severely affected patients. In serum amino acids the only change found was a slight increase in taurine in the worst cases.

It is concluded that estimation of amino acids in urine can give a diagnostic test for even the mildest hepatitis.—D. Duncan.

EVERED, D. F. **The excretion of amino acids by the human. A quantitative study with ion-exchange chromatography.** *Biochem. J.*, 1956, **62,** 416–427. [Med. Unit, University Coll. Hosp. Med. Sch., University St., London, W.C.1.]

Daily excretions of amino acids and midday plasma amino acid levels were estimated by ion-exchange chromatography for 5 healthy subjects, one of whom excreted much β-amino*iso*butyric acid, one child with phenylketonuria, one child and 4 adults with the Fanconi syndrome, 2 subjects with the "Hartnup syndrome", a new form of hereditary aminoaciduria, one adult with cystinuria and 2 adults suffering from a new syndrome in which excessive excretion of glycine occurs and is associated with severe osteomalacia.

The normal subjects and each of the patients studied showed distinct patterns of amino acid excretion ; patients with the same syndrome showed characteristically similar patterns. In the patient with phenylketonuria the output of phenylalanine was high and the plasma level was raised, but phenylalanine clearance was normal. Low or normal plasma amino acid levels were found in the adult form of the Fanconi syndrome, the Hartnup syndrome and β-amino*iso*butyric aciduria. The approximate plasma clearances of some amino acids were of the order to be expected of the glomerular filtration rate. The appropriate plasma clearance of β-amino*iso*butyric acid in the subject

who excreted that substance indicated that little, if any, was re-absorbed from the renal tubule, although the other amino acids were excreted in normal amounts by the subject. β-Amino*iso*-butyric acid was estimated in the urine of 15 healthy men and 9 healthy women; 19 subjects excreted 4 to 28 mg., 3 subjects excreted on the average 55 mg. and 2 subjects excreted 177 and 116 mg. daily.—G. F. Garton.

3281

ROSE, W. C., BORMAN, A., COON, M. J. and LAMBERT, G. F. **The amino acid requirements of man. 10. The lysine requirement.** *J. Biol. Chem.*, 1955, **214**, 579–587. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For parts 9 and 11 see Absts. 5243, Vol. 25 and 695, Vol. 26.

The minimum L-lysine requirement to maintain N balance in normal young men was 0·4 to 0·8 g. daily and the minimum daily requirement is tentatively designated as 0·8 g.; 1·6 g. daily is recommended as a safe allowance when formulating diets to avoid amino acid deficiencies.

In 2 subjects the administration of D-lysine immediately induced negative N balances, and so it is concluded that little, if any, of the D-isomer is utilised by man.—G. F. Garton.

3282

ROSE, W. C., WIXOM, R. L., LOCKHART, H. B. and LAMBERT, G. F. **The amino acid requirements of man. 15. The valine requirement; summary and final observations.**

ROSE, W. C. and WIXOM, R. L. **16. The rôle of the nitrogen intake.** *J. Biol. Chem.*, 1955, **217**, 987–995; 997–1004. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For parts 12, 13 and 14 see Absts. 2002–4, Vol. 26.

15. With the same methods as before, positive N balance was maintained in 5 young men on minimum daily intakes of from 0·8 to 1·6 g. DL-valine. Since L-valine was twice as valuable and D-valine had no value, the minimum daily intake may be expressed as 0·4 to 0·8 g. L-valine, and 1·6 g. L-valine is designed as the safe daily intake.

The work of the whole series of papers, involving 45 human experiments and lasting 12 years, is briefly discussed. The report of Albanese *et al.* (Abst. 2431, Vol. 14) that histidine deficiency led to production of an abnormal indoxyl compound could not be confirmed in tests with 2 subjects, nor could the report from the same source (Holt *et al.*, Title 2376, Vol. 12) that deprivation of arginine adversely affects spermatogenesis.

16. Normal young men received diets with the safe intakes of the 8 essential amino acids and extra N was provided as urea and glycine to bring the daily intake to 10 g. The N balance was studied for 6 days and then the N intake from urea and glycine was reduced in stages, with 4 days for adjustment and a 6-day balance trial at each stage, until the minimum intake compatible with positive balance was found. Intakes of essential amino acids and energy were constant.

There were 2 subjects, each of whom gained weight during the experiment; one weighed initially 82 and the other 67·6 kg. For each the minimum N intake compatible with positive balance was 3·5 g., of which 1·42 g. came from essential amino acids and 0·52 g. was in amino acid isomers believed to be of no value; another 1·21 g. came from glycine and there were small amounts in the rest of the diet. It was concluded that the true minimum requirement was surprisingly small, probably between 2·28 and 2·55 g.—D. Duncan.

3283

AMATUZIO, D. S., HAGEN, P. S. and EVANS, R. L. **The incorporation of N^{15}-labeled glycine in the plasma protein, plasma phospholipids, blood nonprotein nitrogen and splenic tissue in man.** *J. Lab. Clin. Med.*, 1956, **47**, 241–247. [Dept. Med., Univ. Minnesota, Minneapolis.]

Two men, 65 and 73 years old, with hereditary sphaerocytosis were given parenterally glycine labelled with ^{15}N during 24 and 90 hr., respectively. Blood samples were analysed by mass spectrography. The isotope concentration in the phospholipins, plasma protein and N.P.N. rose rapidly to a maximum, the N.P.N. having 3 times as much ^{15}N excess as plasma protein, and then slowly declined. After about 30 days the isotope concentrations in the blood components were almost the same. Curves were drawn from which the rates of disappearance of isotope were calculated. When the spleen was removed from 1 patient after 69 days the splenic pulp (devoid of red blood cells and plasma proteins) had the same excess of ^{15}N as the comparable plasma protein sample.

DESHPANDE, P. D., HARPER, A. E., QUIROS-PEREZ, F. and ELVEHJEM, C. A. **Further observations on the improvement of polished rice with protein and amino acid supplements.** *J Nutrition*, 1955, **57**, 415–428. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

In extension of work already reported (Abst. 699, Vol. 26) groups of 6 rats were given a diet with rice, 87 per cent., and containing maize oil, salts, choline and vitamins. With L-lysine and DL-threonine at 0·4 and 0·5 per cent., respectively, a mixture of histidine, tryptophan, methionine and phenylalanine alone or with arginine, valine, leucine or *iso*leucine prevented deposition of excess fat in the liver but did not improve rate

of growth. When, with these same levels of lysine and threonine, all the essential amino acids were provided, rate of growth was good, but if one acid only were removed it was found that *iso*-leucine, leucine, histidine and, to a less extent, valine were limiting growth; methionine and tryptophan were intermediate in their action and arginine and phenylalanine relatively unimportant. If the amounts of leucine, *iso*leucine, histidine or valine were increased and if tryptophan, methionine and phenylalanine were added, it was still not possible to attain the rate of growth got in the present work with a supplement of good animal protein such as fibrin, pork, casein or kidney meal or in the earlier with a good synthetic diet.

The findings are discussed. It is concluded that more information than is supplied by chemical analyses is required to decide which may be the limiting amino acids in such diets and that a diet which is mainly of rice should, in practice, be supplemented with foods containing well-balanced proteins.—D. Harvey.

SWICK, R. W. and HANDA, D. T. **The distribution of fixed carbon in amino acids.** *J. Biol. Chem.*, 1956, **218,** 577–585. [Div. Biol. Med. Res., Argonne Nat. Lab., Lemont, Ill.]

Rats fed on a diet free of non-essential amino acids and arginine and with $Ca^{14}CO_3$ incorporated much more ^{14}C into the proline, glutamic acid, arginine and aspartic acid of the liver, muscle and small intestine than rats receiving casein. The incorporation into serine, glycine and alanine was only slightly greater. Proline and arginine in the liver seemed to have a precursor other than, or in addition to, glutamic acid, and more than trace quantities of dicarboxylic amino acids could apparently be synthesised from CO_2 and triose.

BAVETTA, L. A. and ERSHOFF, B. H. **Comparative effects of dietary sucrose and cornstarch on tryptophan requirement of the rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 349–351. [Dept. Biochem. Nutrit., Univ. S. California, Los Angeles.]

A synthetic diet free from tryptophan was prepared with 60·8 per cent. sucrose and 24 per cent. of an acid hydrolysate; in a variant of this diet the sugar was replaced by an equal amount of maize starch. To groups of 20 weanling female rats each diet was given alone or with added tryptophan, 0·6, 1·8 or 5·4 g. per kg. diet. For 2 more groups the hydrolysate was replaced by whole casein. Records were kept of bodyweight and of weights of ovaries and uteri until death or to 18 weeks of age, the period for which feeding was continued.

After 28 days on the diets without tryptophan 16 rats survived in the starch but only 1 in the sugar group. With the smallest amount of tryptophan the average weights were all much greater in the starch than in the sugar group, but with the 2 larger amounts there was no difference between the groups. Those with intact casein in place of the hydrolysate did best. It is concluded that the source of carbohydrate in a diet modifies the tryptophan requirement of the rat.

SCOTT, E. B. **Histopathology of amino acid deficiencies. 4. Tryptophan.** *Amer. J. Pathol.*, 1955, **31,** 1111–1129. [Dept. Anat., Sch. Med., Univ. S. Dakota, Vermillion.]

For part 3 see Abst. 2256, Vol. 25.

4. Four rats received a purified diet containing 19 amino acids, 10 others the same diet except that tryptophan was omitted. Others were pair-fed on amounts of control diet equal to those eaten by deprived rats. All were killed after 30 days and tissues were examined histologically.

Some of the changes were similar to those seen earlier in rats deprived of phenylalanine, threonine or histidine, *i.e.*, reduction in size of acidophil cells of the anterior pituitary and complete destruction of basophil cells producing gonadotropic hormone, atrophy of the testes and accessory sex organs and involution of the thymus. Specific effects of deficiency of tryptophan appeared to be moderate to heavy deposition of fat in liver cells, myocardial lesions and deposition of unidentified crystals in the thymus.—D. Duncan.

3288

ARNSTEIN, H. R. V. and KEGLEVIC, D. **A comparison of alanine and glucose as precursors of serine and glycine.** *Biochem. J.*, 1956, **62,** 199–205. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

The radio-activity of serine, glycine, alanine, aspartic acid and glutamic acid was estimated in the proteins of the mixed internal organs of young rats fed for 13 to 20 days on a synthetic diet containing L-[β-^{14}C]-alanine, L-^{14}C-alanine, D-1-^{14}C-glucose or D-^{14}C-glucose.

Glycine, then serine, had the lowest activity in all experiments. Both aspartic and glutamic acids contained more radio-activity after glucose-1-^{14}C than after uniformly labelled glucose, but glycine was less active. Deficiency of pteroylglutamic acid, but not of vitamin B_{12}, reduced the transfer of ^{14}C from alanine or glucose into glycine but not into serine. Degradation of radio-active serine and glycine originating from uniformly labelled glucose showed a uniform distribution of ^{14}C. Serine from glucose-1-^{14}C had 55 to 65 per cent. of the total radio-activity in the β-carbon atom.

Serine was thought to be an important intermediate in glycine biosynthesis. Serine formation did not require pteroylglutamic acid or previous formation of glycine and apparently utilised a C_3 precursor more closely related to an intermediate of the glycolytic pathway of glucose than to pyruvate.—A. Hepburn.

FORBES, R. M., VAUGHAN, L. and NORTON, H. W. **Studies on the utilization of dietary isoleucine by the growing albino rat. 1. Isoleucine requirements determined with amino acid mixtures.** *J. Nutrition*, 1955, **57**, 593–598. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Studies were made on 28 weanling rats given 6 g. daily of diets containing either 10 or 18 per cent. of amino acid mixture and complete except for *iso*leucine. Seven levels of *iso*leucine to each level of amino acid mixture were obtained by the addition of appropriate amounts of a solution containing 24 mg. DL-*iso*leucine per ml. to each diet, equivalent to 1·5, 2·0, 2·5, 3·0, 3·5, 4·0 and 4·5 per cent. L-*iso*leucine in the amino acid mixture. Each period lasted 6 days; urine was collected for estimation of N during the last 4 days. The experiment was so designed that in 3 experimental periods, each of 7 rats received a different amount of *iso*leucine in each period.

The minimum amount of L-*iso*leucine required to promote minimum loss of N in the urine was found to be 2·2 per cent. of the amino acid mixture, or 2·6 per cent. of the conventional protein equivalent of the diets, irrespective of the total N content of the diet.—G. F. Garton.

3290

MERTZ, E. T. and GOLUBOW, J. **Effect of optical antipodes of 6-hydroxy norleucine (hexahomoserine) on growth and hematopoiesis in rats.** *J. Nutrition*, 1956, **58**, 51–58. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

Eight groups of 4 weanling female rats were given a ration containing, per 100 g., casein 19, sucrose 29·8, dextrose 37·75, minerals 5·2, cottonseed oil 5, cod liver oil 1, celluflour 2, vitamin B_{12} 2·2 μg. and vitamin supplement 0·25 g.; the ration contained 1·2 per cent. L-lysine, according to microbiological assay of the casein. Hydroxynorleucine replaced an equivalent amount of dextrose in 7 groups. The resolution of 6-hydroxy-DL-norleucine, the preparation of the enantiomorphs of hydroxynorleucine and the optical purity of the enantiomorphs are described. Food and water were given to appetite. The rats were weighed weekly. On the 28th day, red blood cell counts were made on tail blood.

At the highest level of administration, 1 per cent., the D-isomer reduced the average weight gain to about one-fourth of that of the rats not given hydroxynorleucine, without causing a significant reduction in the average red cell count. The same level of the L-isomer reduced the average weight gain to half of that of the controls and the average red cell count to about one-third.

BENTON, D. A., HARPER, A. E., SPIVEY, H. E. and ELVEHJEM, C. A. **Leucine, isoleucine and valine relationships in the rat.** *Arch. Biochem. Biophys.*, 1956, **60**, 147–155. [Dept. Biochem., Sch. Agric., Univ. Wisconsin, Madison.]

For previous work see Abst. 702, Vol. 26.

The addition of 3 per cent. leucine to a basal diet containing 9 per cent. casein, methionine and tryptophan reduced the growth rate of rats and increased the requirement of both *iso*leucine and valine. At high intakes valine, *iso*leucine and phenylalanine each reduced the utilisation of leucine, and they also antagonised one another.

A. Hepburn.

3292

BENTON, D. A., HARPER, A. E., SPIVEY, H. E. and ELVEHJEM, C. A. **Phenylalanine as an amino acid antagonist for the rat.** *Arch. Biochem. Biophys.*, 1956, **60**, 156–163. [Dept. Biochem., Sch. Agric., Univ. Wisconsin, Madison.]

The addition of 3 per cent. phenylalanine or tyrosine reduced the growth rate of rats fed on the basal diet (cf. previous Abst.). Threonine prevented this, but was only partly effective against a supplement of 5 per cent. phenylalanine. When tryptophan was omitted the reduction of growth caused by phenylalanine was not prevented by threonine. Phenylalanine had no specific antagonism and appeared to affect the utilisation of the amino acid most limiting for growth. Fatty infiltration of the liver caused by deficiency of threonine in the basal diet was reduced by phenylalanine.—A. Hepburn.

CZOK, G. and LANG, K. Über einige Wirkungen von L-Glutaminsäure, D-Glutaminsäure und γ-Aminobuttersäure. [**Some actions of L-glutamic, D-glutamic and γ-aminobutyric acids.**] *Arch. exp. Pathol. Pharmakol.*, 1955, **227**, 214–220. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

Rats weighing 200 to 250 g. received a diet of dried milk and wheatmeal with a little cod liver oil, and drinking water to appetite. They were kept in suspended cages which recorded activity. Activity was recorded for 3 hr. beginning 30 min. after administration by stomach tube of water (control experiments) or solutions of L-glutamic

acid, D-glutamic acid or γ-aminobutyric acid; the amino acids were given to 32, 8 and 24 rats, respectively. In relation to control tests, L-glutamic acid and γ-aminobutyric acid significantly increased activity and D-glutamic acid decreased it, but not significantly. The increases in activity with the 2 first-named amino acids were proportional to intake, but were much greater with γ-aminobutyric than with L-glutamic acid.

The irritability of rats as judged by the response to electrical stimulation was increased by all 3 substances, but L-glutamate was 4 times as effective as D-glutamate and 5 times as effective as γ-aminobutyric acid.

In improvement of flavour of meat broth, tested on men and women, L-glutamate was 26 times as effective as D-glutamate.

In toxicity tests with groups of 8 mice the LD50 of all 3 amino-acids was about 12 g. per kg. bodyweight by mouth. Intra-peritoneal injections gave LD50 for L-glutamate 3·75, for D-glutamate 4·70 and for γ-aminobutyric acid 5·2 g. per kg.

KLOTZSCHE, C. Zur Frage der erhöhten Acetylcholinbildung im Gehirn nach langdauernder Glutaminsäurefütterung. [**Increased formation of acetylcholine in the brain after long-continued administration of glutamic acid.**] *Arch. exp. Pathol. Pharmakol.*, 1956, **227**, 409–413. [Bundesgesundheitsamt, Pettenkofer Inst., Berlin-Dahlem.]

In normal rats the content of glutamic acid plus glutamine, estimated in the pooled organs of 5 animals by the microbiological method of Hac *et al.* (Abst. 2002, Vol. 15) was for brain 180, liver 95 and kidneys 105 mg. per cent.; in white mice, brain 160, liver 90. Giving 1·25 g. *l*(+)-glutamic acid per kg. bodyweight by mouth [daily ?] for 6 weeks raised the values to 340, 185, 150; 280, 170, respectively. Glutamic acid was known to slow the pulse (Klotsche, *Arzneimittel-Forsch.*, 1954, **4**, 85), but it did not do so in rats in which the pulse rate had been raised by cutting the vagi. This suggested that the reduction of pulse rate was due to increased formation of acetylcholine in the brain.

Since work (*e.g.*, Abst. 1269, Vol. 18) on pernicious anaemia had suggested antagonism between folic acid and glutamic acid or acetylcholine, a test was made with 40 mice which had had glutamic acid for 6 weeks. The pulse rate was low in 26. All had glutamic acid for 4 days more, and 1 mg. folic acid per 20 g. bodyweight daily by subcutaneous injection. The effect was to restore pulse rate to normal in 20 of the 26 and to raise it in 12 of the 14 in which it had not been reduced by glutamic acid.

Another experiment with mice showed that folic acid did not affect the toxicity of the cholinesterase inhibitor diethyl*iso*prophylmethylpyrimidyl-thiophosphoric acid ester (Diazinon "Geigy"), that is, folic acid probably does not affect acetylcholine already formed. Hence the work is taken to support the view that folic acid interferes with the metabolism of glutamic acid in the central nervous system by affecting the formation of acetylcholine.—W. M. Deans.

HARPER, A. E. and BENTON, D. A. **Observations on some nutritional factors that influence the lipotropic activity of methionine.** *Biochem. J.*, 1956, **62**, 440–448. [Dept. Biochem., Univ. Wisconsin, Madison.]

Studies were made on 64 groups each of 6 male weanling rats. Diets were given to appetite; all changes in the basal diet were compensated by adjusting the percentage of sucrose. The basal diet consisted of casein 9, sucrose 82, maize oil 5 and salts 4 per cent., with supplements of vitamins of the B group, halibut liver oil fortified to provide vitamins A, D, E and K, and vitamin C. Other supplements were added in different experiments. The experiments lasted for 2, 3 or 5 weeks; at the end each rat was killed and the liver was removed for estimation of fat.

In experiments which lasted for less than 4 weeks fatty infiltration of the liver occurred when the choline in diets which allowed a satisfactory rate of growth was replaced by methionine. The extent of the fatty infiltration was greater when the diet contained 9 per cent. casein and 12 per cent. gelatine than when it contained 18 per cent. casein or more; this was attributed to the low threonine content and the high arginine and glycine content of gelatine. No abnormal accumulation of liver fat was found in rats given either diet for more than 4 weeks; it is suggested that this is due to an increase in the capacity of the young rat to synthesise choline as it matures and that the effect of gelatine is of significance only during early growth, when the animals received diets relatively high in protein and containing additional methionine in place of choline.

KAUFMAN, N., KLAVINS, J. V. and KINNEY, T. D. **Testicular damage following ethionine administration.** *Amer. J. Pathol.*, 1956, **32**, 105–115. [Dept. Pathol., Cleveland City Hosp., Ohio.]

Groups of rats weighing about 220 g. were fed to appetite on a basal diet of glucose 67, vitamin-free casein 18, maize oil 11 (containing 0·001 ml. haliver oil) and salt mixture 4 per cent., with, per 100 g. diet, thiamine chloride 400, pyridoxine hydrochloride 400, riboflavin 800 μg., nicotinic acid 2·5 and calcium pantothenate 1·5 mg., or the same with 0·5 per cent. DL-ethionine, or were given the basal diet restricted so as to match the weight changes in the group given ethionine. After 28 days some of the rats on ethionine stopped getting it. Rats were killed after 10, 28 and 63 days and changes in the testes were graded histologically; photomicrographs are reproduced.

Rats given ethionine lost weight at first and their subsequent gains were trifling. They showed progressive testicular degeneration, which is described in detail; in rats which stopped getting ethionine, regeneration took place. The results for the rats on restricted food intake clearly showed that it was the ethionine and not the associated reduction of food intake that was to blame. It is suggested that methionine is essential for spermatogenesis.

HAGGAR, R., KINNEY, T. D. and KAUFMAN, N. **Bone healing in lysine-deficient rats.** *J. Nutrition*, 1955, **57**, 305–317. [Dept. Pathol., Cleveland City Hosp., Ohio.]

One hundred and four young adult male rats were divided into 4 equal groups. One group was given a basal, lysine-free diet of zein 22·3, L-arginine 1, DL-valine 1, DL-histidine HCl 0·5, DL-tryptophan 0·2, salt mixture 4, dilute halibut oil 0·5, vitamins of the B group 0·0056, maize oil 10·5 and glucose 60 per cent.; the second group received the basal diet containing 1 per cent. lysine and the third group the basal diet containing 3 per cent. lysine; these 3 groups were fed to appetite. The fourth group was given the basal diet plus 1 per cent. lysine in restricted amount so that their weight loss was equal to that of the lysine-free group. After 21 days the animals were anaesthetised and a surgical lesion was made in each tibia. Two animals from each of the 4 groups were killed at 1½-day intervals up to 9 days, at 3-day intervals up to 24 days and at 32 and 40 days, and the extent of healing of the lesions was examined histologically.

Lysine deficiency and starvation retarded epiphyseal growth but did not retard the healing of the bone lesions. Other effects of lysine deficiency were similar to those produced by restricted food intake and included loss of weight, retarded skeletal and visceral growth and atrophy of subcutaneous fat and muscles. When the lysine was increased from 1 to 3 per cent. there was no effect on growth or the healing of bone lesions.—G. F. Garton.

AWAPARA, J. **The taurine concentration of organs from fed and fasted rats.** *J. Biol. Chem.*, 1956, **218**, 571–576. [Univ. Texas, Houston.]

The average concentration of taurine in μmoles per g. fresh tissue from 6 male and 6 female rats was heart 27·6, spleen 12·2, small intestine 11·4, muscle 10·1, kidney 7·8, uterus 7·2, brain 5·5 and testis 2·2. The concentration in the liver was 5·3 for females and 1·6 for males. In general the tissues of the rat had a higher taurine concentration than those of the guineapig and rabbit. In rabbits taurine was not detected in the liver. Ox and sheep hearts contained much less taurine than pig and rodent hearts.

After fasts of 7 days taurine had increased in the skeletal muscle and liver of male rats and decreased in the liver of females. Other tissues were not affected. Hypophysectomy, and to a slighter extent adrenalectomy, increased the taurine concentration in the skeletal muscle, spleen and kidney of male rats. Adrenalectomy or ovariectomy decreased the concentration in the liver in the female rat. The average taurine excretion in the urine was greatly increased by intake of cysteine, but represented only 20 per cent. of the total cysteine. It was concluded that taurine is utilised for purposes other than the formation of bile salts.—A. Hepburn.

MCCANCE, R. A. and WIDDOWSON, E. M. **Protein catabolism and renal function in the first two days of life in premature infants and multiple births.** *Arch. Dis. Childhood*, 1955, **30**, 405–409. [Med. Res. Counc. Dept. Exp. Med., Univ. Cambridge.]

Two premature babies weighing 2 kg. at birth, 4 pairs of twins weighing between 2 and 3 kg. and 1 set of triplets weighing 1 kg. were studied. Data on concentration of urea in serum and volume and composition of urine in the first 48 hr. of life are tabulated. Only in the triplets was there evidence of abnormally high protein catabolism and impaired renal function.—F. C. Aitken.

MATTEUCCI, G. B. and ABBATANTUONO, N. La curva lipemica alimentare nel lattante normale. **[The curve of alimentary lipaemia in the normal infant.]** *Arch. ital. Pediat. Puericolt.*, 1956, **18**, 65–80. [Inst. Clin. Paediat., Univ. Rome.] French, English and German summaries.

Blood lipids were studied in 54 normal infants aged from 6 days to 7 months, half of them breast-fed and half fed on dried milk. The infants received water only for 12 hr. before fasting values for blood lipids were estimated, and further estimates were made 1, 3, 5 and 7 hr. after a meal, and also after 9 hr. in the artificially fed infants. The latter received milk with 3·5 per cent. fat.

The results are given in tables. Fasting blood lipids ranged in the breast-fed infants from 428 to 585 mg. per 100 ml., mean 513, and in the artificially fed infants from 434 to 580, mean 511. In 18 of the 27 breast-fed infants the peak value was at the third hour after the meal; the greatest increase was 34 and the mean 14·7 mg. per 100 ml. After 5 hr. 5 infants had shown a further increase, but the mean was only 4·4 mg. above the fasting value, and after 7 hr. it was below the fasting value. In the artificially fed group the increase of blood lipids was much greater and more persistent; the mean increase above the fasting value was 48·6 mg. at 3 hr., 54·8 at 5 hr. and 26·6 at 7 hr.; only after 9 hr. was the fasting value regained.

DROESE, W. and STOLLEY, H. Untersuchungen über den Fettstoffwechsel im Säuglingsalter. 1. Gesamtfett-, Fettsäuren und Phosphatidbilanzen bei Säuglingen mit parenteralen Infektionen, ein Beitrag zur Pathogenese der parenteral bedingten Ernährungsstörung im Säuglingsalter. **[Metabolism of fat in infancy. 1. Balance of total fat, fatty acids and phosphatides in infants with parenteral infections, a contribution to the pathogenesis of parenterally induced disturbances of nutrition in infancy.]** *Ztschr. Kinderheilk.*, 1956, **77**, 532–543. [Kinderklin., Univ. Kiel.]

Balances of total fat, saturated and unsaturated fatty acids and phosphatides were studied in 15 artificially fed infants aged from 1 to 9 months. Some were convalescent, others had slight respiratory infections without digestive disturbance, or bacterial infections of the skin.

Even slight respiratory infections interfered with the utilisation of dietary fat, but skin infections had little or no ill effect on it. Utilisation of saturated fatty acids and phosphatides was most affected.

Some experiments are described in full.

D. Duncan.

KEYS, A. **The claim of "Lack of effect of high fat intake on serum lipid levels" by Mann, G. V.,** *Amer. J. Clin. Nutrit.*, 1955, **3**, 230. *Amer. J. Clin. Nutrit.*, 1956, **4**, 74–76. [Lab. Physiol. Hyg., Sch. Pub. Health, Univ. Minnesota, Minneapolis.]

A rise in serum lipid levels in response to a high fat intake was reported by Mann (Abst. 5272, Vol. 25) but dismissed by him as statistically unimportant. Keys points out a fallacy in Mann's statistical procedure and indicates that Mann's conclusion was not supported by the data. Mann accepts the statistical implications of Keys's criticism but remains doubtful of the practical importance of the rise in serum lipid.

MARINA FIOL, C., JIMÉNEZ DÍAZ, C. and ROMEO ORBEGOZO, J. M. Estudios experimentales sobre la esteatorrea de origen pancreatico. **[Experimental studies on steatorrhoea of pancreatic origin.]** *Rev. clín. española*, 1955, **59**, 294–300. [Clín. Méd., Fac. Med., Madrid.] English, German and French summaries.

Fatty acids, neutral fat and total lipids were estimated after diets providing 20 and 70 g. fat daily in normal dogs, dogs with all or part of the pancreas removed and dogs with selective destruction of the acinar cells produced by *dl*-ethionine.

Dogs with the pancreas removed or damaged utilised dietary fat at both intakes as well as did normal dogs, but there was an increase in the percentage of faecal fat because of a decrease in total faecal output.

It is considered that in pancreatic disorders there is no loss of ability to break down fats, but an increased excretion of fat into the intestine and increased deposition of fat in liver and kidneys.

MOELLER, H. C., BERNSTEIN, L. M., PALM, L. and GROSSMAN, M. I. **The effect of protamine on**

lipemia. *J. Lab. Clin. Med.*, 1956, **47**, 270–278. [U.S. Army Med. Nutrit. Lab., Fitzsimons Army Hosp., Denver, Colo.]

Ten fasting normal men were given 2 separate intravenous infusions of 500 ml. of a fat emulsion 1 week apart; one infusion was given with and one without protamine sulphate. The fat emulsion contained refined cottonseed oil 15, glucose 4, soya bean phospholipins 1·2 and Pluronic F-68 0·3 per cent. Venous blood samples were taken at intervals up to 300 min. after the infusions and examined for optical density and free and total fatty acid content of the serum.

It was concluded that the simultaneous infusion of protamine with fat emulsion delayed the rate of removal of lipids from the blood. In further experiments in which alimentary lipaemia was induced by giving the fat emulsion by stomach tube the intravenous infusion of protamine brought about a moderate rise of blood lipids above values in the absence of protamine.

Similar studies with rats showed that protamine given by vein increased alimentary lipaemia. When protamine was injected immediately before injection of the fat emulsion the removal of lipids from the blood was delayed; but when the injection of protamine preceded that of the fat emulsion by 15 min. the delay was considerable.

HERTING, D. C., AMES, S. R., KOUKIDES, M. and HARRIS, P. L. **The digestion of acetylated monoglycerides and of triglycerides.** *J. Nutrition*, 1955, **57**, 369–387. [Res. Labs., Distillation Products Indust., Div. Eastman Kodak Company, Rochester, N.Y.]

Lipids were recovered from the stomach, small intestine, caecum and colon and faeces of adult male rats fed for at least 5 days on diets containing about 21·5 per cent. cottonseed oil, lard, hydrogenated lard or distilled acetylated glycerides. The lipids were analysed for free fatty acids, fatty acids from soaps, monoglycerides, di- and triglycerides and, where appropriate, mono-acetylated monoglycerides.

With partly unsaturated triglycerides from lard and cottonseed oil little breakdown of fat occurred in the stomach, though extensive intestinal digestion was accompanied by rapid absorption. The digestion of hydrogenated lard was similar, except that more digestion occurred in the stomach; intestinal absorption was poor in spite of considerable intestinal digestion. Similar findings are reported for the digestion of distilled acetylated saturated monoglycerides. The digestion of distilled, acetylated mixed saturated and unsaturated monoglycerides was intermediate between that for the saturated and unsaturated triglycerides.

3309

KRITCHEVSKY, D., MCCANDLESS, R. F. J. and NORTON, T. W. **The distribution of radioactivity in monkey serum lipids following feeding of triolein-^{3}H.** *Biochim. biophys. Acta*, 1956, **19**, 557–558. [Viral and Rickettsial Res., Res. Div., American Cyanamid Co., Lederle Labs., Pearl River, N.Y.]

Tritium-labelled triolein was given by stomach tube to 2 male Java monkeys and blood samples were taken 2 hr. later and at intervals for 3 or 7 days. Lipids were extracted from the serum and separated into steryl esters, neutral fat, free sterols, phospholipins and fatty acids by chromatography on silicic acid (Abst. 61, Vol. 24); each fraction was assayed for radio-activity.

Most of the radio-activity was found in the neutral fat and fatty acid fractions of the serum lipids between 2 and 6 hr. after the labelled fat was administered.—G. A. Garton.

3310

AMBROSE, A. M. and ROBBINS, D. J. **Studies on comparative absorption and digestibility of acetoglycerides.** *J. Nutrition*, 1956, **58**, 113–124. [Pharmacol. Sect., W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany, Calif.]

The extent of intestinal absorption of several "synthetic" triglycerides was studied in rats. Groups of 10 rats, fasted for 48 hr., were given a meal containing 20 per cent. of the fat under investigation and the amount of fat eaten in 30 min. was calculated. Four hours later the rats were killed for estimation of the fat content of the digestive tract; similar studies on rats starved for 48 hr. gave the amount of endogenous fat. Digestibility coefficients were calculated for each fat according to the procedure of Augur *et al.* (Abst. 2138, Vol. 17). The fats examined included "acetostearins" and "aceto-oleins", defined as acetylated monoglycerides derived from highly hydrogenated lard or vegetable oils and those derived from cottonseed oil or edible lard; similar studies were made with Crisco, a partly hydrogenated vegetable oil.

The aceto-oleins were absorbed to the extent of 76 to 77 per cent., the acetostearins to about the same extent as Crisco, 67 per cent. The acetoglycerides were digested in much the same way as natural fats. The coefficients of digestibility were about 99 per cent. for the aceto-oleins, 80 and 80·8 per cent. for acetostearins melting at 30·7° and 57° C. and 85 per cent. for acetostearin melting at 32·5° C.; for mixtures of 15 per cent. acetostearin and 5 per cent. aceto-olein and for 10 per cent. acetostearin plus 10 per cent. aceto-olein the digestibilities were 85·1 and 93·7 per cent.

The lower digestibility of acetostearins may be due to the formation of calcium stearate in the intestinal tract.—G. A. Garton.

3311

BENTON, D. A., HARPER, A. E. and ELVEHJEM, C. A. **The effect of different dietary fats on liver fat deposition.** *J. Biol. Chem.*, 1956, **218**, 693–700. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of male weanling rats were fed to appetite for 2 weeks on diets containing 20 per cent. maize oil, butterfat, margarine or lard and 9 per cent. casein. The livers were then removed for estimation of ether-extractable fat.

Liver fat values were higher after diets containing butterfat or lard than after margarine or maize oil. This effect was more pronounced when the casein was reduced to 7 per cent. and even greater when choline was omitted from the diet.

In similar experiments it was found that the solid fatty acids, especially stearic acid, of butterfat occasioned a greater deposition of liver fat than did the liquid fatty acids; the unsaponifiable matter of butterfat had no effect.—G. A. Garton.

3312

CONIGLIO, J. G., DARBY, W. J., EFNER, J. A., FLEMING, J. and HUDSON, G. W. **Effect of total body X-irradiation on fat balance and liver lipids in the rhesus monkey.** *Amer. J. Physiol.*, 1956, **184**, 113–118. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Adult female rhesus monkeys, initially fed on a stock monkey diet supplemented with 50 mg. ascorbic acid and later given a purified diet containing 5 per cent. cottonseed oil, were exposed to X-rays at 325, 400 and 650 r over the whole body. Faeces were collected before and after treatment and total fat was estimated. Liver lipids of monkeys exposed to 650 r were studied also.

Fat absorption did not appear to be affected by exposure and the increased excretion of fat after exposure was found also in untreated pair-fed animals. Liver lipids of exposed monkeys were similar to those of pair-fed controls.

Some haematological observations are included.

AAES-JØRGENSEN, E., FUNCH, J. P., ENGEL, P. F. and DAM, H. **The role of fat in the diet of rats. 8. Influence on growth of shortening products, 'emulsifier PT 006' and polymerized linseed oil.** *Brit. J. Nutrition*, 1956, **10**, 32–39. [Dept. Biochem. Nutrit., Polytech. Inst., Copenhagen.]

For part 7 see Abst. 3832, Vol. 25.

8. Groups of male rats were reared for 36 weeks from weaning on diets containing 30 per cent. of different shortenings (cooking fats for cakes and pastries), supplying 20 per cent. fat, or 30 per cent. of a 2 : 1 mixture of PT 006 (partial polyglycerol ester of polymerised soya bean oil) and soya bean oil, or a 2 : 1 mixture of PT 006 plus polymerisation distillate and soya bean oil, or a 2 : 1 mixture of polymerised linseed oil and soya bean oil. Control animals were given a diet containing 30 per cent. soya bean oil. Growth rates were recorded and at the end the rats were killed for examination of the carcase and kidneys, liver and small intestine were removed for histological study.

Rats given the diets containing shortenings grew satisfactorily and no pathological change was found in liver or small intestine. All the rats given polymerised linseed oil died during the first half of the experiment. The animals given diets containing PT 006, with or without its polymerisation distillate, grew more slowly than the control group. Histological examination of the tissues showed pathological changes in the kidneys, liver and small intestine.—G. A. Garton.

3314

DOLE, V. P. **A relation between non-esterified fatty acids in plasma and the metabolism of glucose.** *J. Clin. Invest.*, 1956, **35**, 150–154. [Rockefeller Inst. Med. Res., New York.]

"Non-esterified fatty acids" is the term used to define the acids of plasma which are liberated from protein combination by shaking 1 ml. plasma with 5 ml. of a mixture of 40 parts *iso*propanol, 10 parts heptane and 1 part N H_2SO_4; the extracted acids are then estimated titrimetrically.

In studies on human subjects non-esterified fatty acids fell after a mixed meal and remained below fasting values for 2 hr. or more. When a fat meal was given in amount sufficient to cause pronounced lipaemia no effect on non-esterified fatty acids was found. Falls of non-esterified fatty acid values comparable to those after a mixed meal were found after oral administration of 50 g. glucose and after subcutaneous injection of insulin. Very high levels were produced by injection of 0·5 mg. adrenaline.

Normal fasting values for non-esterified fatty acids were recorded for 3 men, each of whom had abnormally high total plasma lipids, neutral fat, cholesterol and phospholipins.

The effects of glucose, insulin, adrenaline and fasting on these fatty acids resembled their effects on ketosis, and it is suggested that both these fatty acids and ketone bodies participate in a metabolic process common to fat and carbohydrate.

G. A. Garton.

3315

GORDON, R. S. (Jr.) and CHERKES, A. **Unesterified fatty acid in human blood plasma.** *J. Clin. Invest.*, 1956, **35**, 206–212. [Lab. Metabol., Nat. Heart Inst., Bethesda, Md.]

In studies similar to those reported in the preceding abstract, unesterified fatty acids in the plasma of several hospital patients were estimated by the method of Davis (Abst. 73, Vol. 18).

Large fluctuations in unesterified fatty acids were found from time to time in normal subjects. Values tended to rise after a fatty meal with eggs, cream, bacon or margarine, but similar increases were found also in fasting subjects. Carbohydrate digestion was accompanied by a fall in unesterified fatty acids, and the intravenous infusion of adrenaline brought about higher values. It is suggested that unesterified fatty acids are the fraction of blood lipids concerned with the supply of fatty acids to the tissues for oxidation.

3316

LIPSKY, S. R., MCGUIRE, J. S. (Jr.), BONDY, P. K. and MAN, E. B. **The rates of synthesis and the transport of plasma fatty acid fractions in man.** *J. Clin. Invest.*, 1955, **34**, 1760–1765. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Acetate-1-^{14}C was given by mouth to hospital patients with limited expectancy of life. Blood samples were taken at intervals for up to 48 hr. and the radio-activity of the fatty acids of plasma phospholipins and non-phospholipins was measured.

The formation and turnover of fatty acids in the non-phospholipin fraction was much more rapid than in the phospholipin fatty acids. It is suggested that the non-phospholipins of the plasma may be the major means of transport of fatty acids.

A similar study was made in which large quantities of squalene were given to patients who were also given labelled acetate. The administration of squalene, which depressed utilisation of acetate for cholesterol synthesis, did not affect the incorporation of acetate into plasma fatty acids.

3317

MEAD, J. F., SLATON, W. H. (Jr.) and DECKER, A. B. **Metabolism of the essential fatty acids. 2. The metabolism of stearate, oleate, and linoleate by fat-deficient and normal mice.** *J. Biol. Chem.*, 1956, **218**, 401–407. [Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

Methyl stearate, methyl oleate or methyl linoleate, each labelled with ^{14}C in the carboxyl group, was given by mouth to fat-deficient and normal mice. The mice were housed individually in glass metabolism cages and the respired CO_2 was collected hourly for 8 hr. and then 2 and 16 hr. later. The mice were then killed for extraction and analysis of carcase lipids.

As judged by the output of $^{14}CO_2$, the fat-deficient mice metabolised stearate and linoleate at a significantly higher rate and oleate at a lower rate than did normal mice. The extent of incorporation of ^{14}C into cholesterol appeared to be less the more ^{14}C was respired as $^{14}CO_2$. No evidence was obtained to suggest conversion of oleate to linoleate.—G. A. Garton.

3318

TOVE, S. B., ANDREWS, J. S. (Jr.) and LUCAS, H. L. **Turnover of palmitic, stearic, and unsaturated fatty acids in rat liver.** *J. Biol. Chem.*, 1956, **218**, 275–281. [Nutrit. Sect., Dept. Animal Indust., N. Carolina State Coll., Raleigh.]

Weanling male rats on a fat-free purified diet were given an intraperitoneal injection of ^{14}C-carboxyl-labelled acetate. Rats were killed every 4 hr. for 44 hr., beginning 2 hr. after the acetate injections. Fatty acids were prepared from the neutral fat and phospholipin fractions of liver lipids and chromatographed to yield palmitic and stearic acids and unsaturated acids, the specific radio-activity of each of which was studied; specific activity-time curves were then prepared.

Two distinct peaks were found in the specific activity-time curves for the individual fatty acids of the phospholipin and neutral fat fractions; no difference was found in the rates of metabolism of the phospholipin fatty acids and the palmitic acid and unsaturated acids of the neutral fat; the rate of metabolism of the stearic acid of the neutral fat did appear to be slower than that of the other fatty acids. The specific activity of the stearic acid of the phospholipins was about 8 times that of the stearic acid of neutral fat.

G. A. Garton.

3319

KLENK, E. Über die Biogenese der C_{20}- und C_{22}-Polyenfettsäuren. [**Biogenesis of the C_{20} and C_{22} polyene fatty acids.**] *Hoppe-Seyler's Ztschr.*, 1955, **302**, 268–277. [Physiol. Chem. Inst., Univ. Cologne.] English summary.

Adult rats were fed on bread, oats and carrots. One rat received a single dose of labelled acetate, $CH_3{}^{14}COONa$, providing 0·13 mC., and 2 others had a single dose of 0·18 mC.; all 3 were killed 2 hr. later. Three rats received a total of 0·60 mC. in 3 doses in the course of 24 hr. and were killed 6 hr. after the last dose. Livers were prepared as quickly as possible for extraction of fatty acids. In a fourth experiment the liver of 1 rat

was incubated for 6 hr. at 37° C. in Ringer's solution with labelled acetate.

The ^{14}C was found among the dicarboxylic acids mainly in succinic and glutaric acid. It was present also in higher dicarboxylic acids, but malonic acid was only slightly labelled. It was concluded that C_{20} and C_{22} polyene acids in rat liver are formed from linoleic and linolenic acids by addition of acetate at the carboxyl end.

OGATA, K., OHTAKE, S., KAWANO, H., KITAGAWA, K., TOMINAGA, H. and AKIYAMA, T. **Experimental study on the toxicity of highly unsaturated fatty acids. Histopathologic reactions induced by this material obtained from cuttle-fish.** *Tokushima J. Exp. Med.*, 1955, **2**, 150–155. [Dept. Pathol., Sch. Med., Tokushima Univ.]

The ethyl esters of the mixed fatty acids of cuttlefish oil were distilled *in vacuo* to yield a fraction of saponification value 163·5, iodine value 344·1 and peroxide value 0. The esters were allowed to oxidise in air at room temperature for 2, 3, 5 and 7 days. The oxidised esters, 0·2 ml., were then given by mouth weekly to white rats which each received 10 g. daily of diet consisting of rice flour 79, casein 10, McCollum salt mixture 3, yeast 3 and water 5 per cent. Animals which died during the 76th to 81st days of the experiment were examined histologically.

In addition to depilation round the mouth and of the legs, decreasing bodyweight and paralysis, the experimental animals showed extensive degenerative changes in the liver, spleen and kidney.

In further experiments 0·05 ml. of another fraction of oxidised ethyl esters was given daily to white rats. The esters, which initially had a peroxide value of 1753, were allowed to oxidise further for 10, 30 and 60 days. [The period during which the esters were given to the rats is not stated, neither is the composition of the basal diet which the animals presumably received.] Histopathological changes are described in liver, spleen, kidney, thyroid, heart, lung, lymph nodes and stomach. The degenerative changes were not as marked after the administration of esters which had continued to oxidise for 60 days, presumably because of reduction in the peroxide value.

STEINER, A. and DAYTON, S. **Production of hyperlipemia and early atherosclerosis in rabbits by a high vegetable fat diet.** *Circulation Res.*, 1956, **4**, 62–66. [Res. Serv., First (Columbia Univ.) Div., Goldwater Mem. Hosp., New York.] Interlingua summary.

Cholesterol, phospholipin and total fat concentrations were increased, as was the cholesterol : phospholipin ratio, in the serum of rabbits given a diet rich in vegetable fat. Microscopic examination showed lipid infiltration of the ascending and thoracic aorta in 10 of 35 rabbits at the end of 5 to 12 months. Small areas of gross aortic atherosclerosis were found in 2 rabbits.—A. K. Lough.

3324

CHAKRAVARTI, R. N., DE, U. N. and MUKERJI, B. **Studies in experimental atherosclerosis. 1. Effect of feeding different vegetable fats on the pathogenesis of atherosclerosis in animals (rabbit).** *Indian J. Med. Res.*, 1956, **44**, 49–57. [Central Drug Res. Inst., Lucknow.]

Four groups of 6 young Indian inbred rabbits were fed for 28 weeks on a diet of gram, bran and green vegetables, supplemented in 3 of the groups with 5 ml. cottonseed oil, coconut oil or groundnut oil daily. Blood samples were taken at intervals for estimation of total and ester cholesterol, urea N, total protein, albumin and globulin ; the fat content of faeces collected from each animal during 24 hr. was estimated. At the end the animals were killed and the blood vessels and organs were examined visually and histologically for lesions.

The blood cholesterol did not vary much between the 4 groups ; the group fed on coconut oil showed the lowest values. At autopsy, fatty infiltration of the lungs and heart was found in some animals from each group given extra fat ; fatty livers were found in 2 of the rabbits which had had coconut oil. The aortic intima of 2 of those given groundnut oil showed reticular proliferation with deposition of collagen.—G. A. Garton.

FRIEDMAN, M. and BYERS, S. **Role of hyperlipemia in the genesis of hypercholesteremia.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 496–499. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Sustained elevation of blood lipids was induced in male rats by rapid intravenous injection of 3 ml. of an emulsion containing 10 per cent. sesame oil or coconut oil and 1 per cent. soya bean lecithin, followed by continuous intravenous injection of the same emulsion at the rate of 0·9 to 1·2 ml. per hr. for 12 hr. The rats had each received 3 ml. olive oil by stomach tube 72, 48 and 24 hr. before the experiment. Plasma samples obtained before and immediately after injection of the 3 ml. emulsion and also 12 hr. later were analysed for cholesterol and phospholipins.

Compared with control animals which were given 5 per cent. glucose solution instead of fat emulsion, the experimental animals had high plasma cholesterol values, especially after the fat emulsions had been given for 12 hr. High plasma cholesterol was not found in partly hepatectomised rats which were similarly injected with fat emulsions. High blood fat induced in fasting rats by the injection of protamine was not accompanied by high plasma cholesterol, though high plasma cholesterol was found in rats given olive oil by mouth and injections of protamine.

It is suggested that high plasma cholesterol values associated with high blood fat may be associated with a primary derangement of the metabolism of plasma lipids other than cholesterol.

JONES, R. J. **Serum cholesterol reduction in patients by the oral administration of a brain extract.** *J. Lab. Clin. Med.*, 1956, **47,** 261–269. [Div. Biol. Sci., Dept. Med., Univ. Chicago, Ill.]

Nine patients with coronary artery disease and with high values for blood cholesterol ate about 30 g. daily of ox brain cerebrosides for 3 to 8 weeks. In every patient there was a fall in serum cholesterol, and a significant, though smaller, reduction in the serum phospholipins, neutral fat and β-lipoproteins; α-lipoproteins were not significantly affected.—G. A. Garton.

KRITCHEVSKY, D., MOYER, A. W., LOGAN, J. B. and MCCANDLESS, R. F. J. **Effect of state of administered cholesterol in experimental atherosclerosis.** *Arch. Biochem. Biophys.*, 1955, **59,** 526–527. [Viral and Rickettsial Sect., Res. Div., American Cyanamid Company, Pearl River, N.Y.]

Five groups of 8 to 10 rabbits were fed for 8 weeks on chow with 2 per cent. cholesterol applied in a volatile solvent, chow with 2 per cent. cholesterol applied in a non-volatile solvent, chow with 2 per cent. cholesterol suspended or dissolved in 6 per cent. maize oil, pellets containing 2 per cent. cholesterol and the same pellets mixed with 6 per cent. maize oil. The animals were killed and the thoracic aorta and aortic arch were examined visually for atherosclerotic plaques; serum cholesterol was estimated.

The extent of plaque formation was greatest in the rabbits given chow with cholesterol in a volatile solvent; differences in the extent of plaque formation in the other groups suggested that the form in which cholesterol is administered may be of importance in determining the degree of severity of the resulting atheromatous lesions. Serum cholesterol showed a wide range of values in all the groups.—G. A. Garton.

3328

KRITCHEVSKY, D., MOYER, A. W., TESAR, W. C., LOGAN, J. B., MCCANDLESS, R. F. J. and DAVIES, M. C. **Effect of injected choline citrate in experimental atherosclerosis.** *Amer. J. Physiol.*, 1955, **183,** 535–537. [Viral and Rickettsial Sect., Res. Div., American Cyanamid Company, Pearl River, N.Y.]

Choline citrate injected intraperitoneally at 50 or 250 mg. daily into rabbits on a diet containing 2 per cent. cholesterol in maize oil produced lower serum cholesterol and fewer and smaller atheromata in the arch and thoracic portion of the aorta than were found in rabbits on the same diet without injection. Sodium citrate injected had the same effect on blood cholesterol, but did not affect the extent of the atheromata. Choline chloride injected had no effect on either. None of the salts had any effect when given by mouth.

ROTH, M. and FAVARGER, P. La digestibilité des graisses en présence de certains stérols. [**The digestibility of fats in the presence of certain sterols.**] *Helv. physiol. pharm. Acta*, 1955, **13,** 249–256. [Inst. Chim. Physiol., Univ. Geneva.]

The addition of cholesterol, sitosterol or ergosterol to olive oil or beef fat in the diet of groups of rats did not significantly alter the digestibility of the fats.

Deuterium-labelled cholesterol, sitosterol or cholestanol was added to the diet of rats which were receiving tripalmitin labelled with deuterium. About 66 per cent. of the tripalmitin was absorbed, and the percentage absorption of cholesterol, sitosterol and cholestanol was 46·6, 27·8 and 27·4. The sterol content of the intestinal wall was

greater when cholesterol was being absorbed than when sitosterol was being absorbed.

It is suggested that the selectivity in the intestinal absorption of the different sterols is not compatible with their being absorbed in the "particulate" state and that a much more finely divided state may be necessary for selective absorption.—G. A. Garton.

COOK, R. P., EDWARDS, D. C. and RIDDELL, C. **Cholesterol metabolism. 7. Cholesterol absorption and excretion in man.** *Biochem. J.*, 1956, **62,** 225–234. [Dept. Biochem., Queen's Coll. (Univ. St. Andrews), Dundee.]

7. The intestinal excretion of unsaponifiable matter was studied in a man aged 45, after ingestion of crystalline cholesterol in olive oil and after cholesterol taken in eggs.

The apparent absorption of crystalline cholesterol in 3 days was about 15 per cent., that of egg cholesterol about 60 per cent. in 4 days. With egg the plasma concentration of esterified cholesterol showed a transitory increase. The composition of the neutral fraction in faecal extract before and after ingestion of cholesterol appears to be similar to that of the rat (Abst. 2043, Vol. 26).

FRIEDMAN, M., BYERS, S. O. and ST. GEORGE, S. **Detection of dietary cholesterol-4-C^{14} in the hepatic reticulo-endothelial cell of the rat.** *Amer. J. Physiol.*, 1956, **184,** 141–144. [Harold Brunn Inst. Cardiovascular Res., Mount Zion Hosp., San Francisco, Calif.]

Male rats were injected intravenously with a saline suspension of starch-iron powder daily for 3 days. Before the last injection cholesterol-4-^{14}C in olive oil was given by stomach tube, and the animals were killed within 24 hr. Hepatic reticulo-endothelial cells were separated from parenchymal cells by centrifuging and electromagnetic manipulation. Radio-activity was studied in liver cell fractions and in sterol digitonide extracts of these fractions.

Both reticulo-endothelial and parenchymal cells showed radio-activity 6 and 24 hr. after ingestion of cholesterol.—A. K. Lough.

SCHWENK, E., ALEXANDER, G. J. and FISH, C. A. **Studies on the biosynthesis of cholesterol. 8. Tissue distribution of cholesterol and presence of precursors in intact animals.** *Arch. Biochem. Biophys.*, 1955, **58,** 37–51. [Worcester Found. Exp. Biol., Shrewsbury, Mass.]

The distribution in different tissues of radio-active cholesterol and radio-active substances accompanying it in the nonsaponifiable lipids (HCC) was studied after intraperitoneal injection of acetate-1-^{14}C into rats, guineapigs, dogfish and a rainbow trout.

The main formation of labelled cholesterol in guineapigs and rats occurred in the liver and digestive tract in the period 30 to 60 min. after injection of the radio-active acetate. No HCC were detected in the liver cholesterol of rats except in the first 3 min. of the experiment, though HCC were found in the digestive tract during the first hour after injection; after 4 hr. they were no longer detected. In guineapigs HCC were present with labelled cholesterol in both liver and digestive tract for a considerable time, indicating that these animals do not synthesise cholesterol as readily as rats do. The experiments with fish showed very slow formation of cholesterol, though HCC were found in all tissues examined.

The HCC isolated from rats and guineapigs were given by mouth to rats and shown to give rise to labelled cholesterol.—G. A. Garton.

CURRAN, G. L. and COSTELLO, R. L. **Effect of dihydrocholesterol and soybean sterols on cholesterol metabolism in rabbit and rat.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 52–56. [Dept. Med., Univ. Kansas Sch. Med., Kansas City, Mo.]

Male rabbits were given 3 g. dihydrocholesterol or 3 g. mixed soya bean sterols 3 times a week for 4 weeks; blood and tissue samples were then removed for examination. Groups of rats were fed on diets containing 1 per cent. dihydrocholesterol or 3 per cent. mixed soya bean sterols; 3 animals from each group were killed weekly for 5 weeks and the livers were removed for examination of their sterol content. Liver cell preparations from rabbits and rats were incubated with ^{14}C-carboxyl-labelled acetate and its incorporation into cholesterol was studied.

Soya bean sterols in rabbits produced atherosclerosis, but dihydrocholesterol did not. Liver

tissue from rats and rabbits which had been fed on diets containing dihydrocholesterol and soya bean sterols showed impaired ability to incorporate acetate into cholesterol. Rats given the diet containing 3 per cent. soya bean sterols did not absorb significant amounts of these compounds and no fall in liver sterol values was found.

G. A. Garton.

3335

ROSENMAN, R. H. and SMITH, M. K. **The effect of certain chelating substances (EDTA) upon cholesterol metabolism in the rat.** *J. Clin. Invest.*, 1956., **35,** 11–19. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

The high concentration of plasma cholesterol in rats on a diet rich in cholesterol was much increased when salts of ethylenediamine tetra-acetic acid (EDTA) were included. The effect was greater with disodium EDTA than with tetra-sodium EDTA or disodium calcium EDTA. The plasma cholesterol of rats on a diet with added disodium EDTA but no added cholesterol showed no change in concentration.

Oral administration of disodium EDTA to rats increased the absorption of dietary cholesterol, but did not appear to alter the rate of formation of cholesterol in the liver or the rate of disappearance of cholesterol from the plasma.

GLIDDEN, M. A., MORRISON, R. I. and MOSCHETTE, D. S. **Metabolic studies with pre-adolescent girls. 4. Utilization of calcium.** *J. Amer. Dietetic Assoc.*, 1956, **32,** 29–35. [Dept. Home Econ., Louisiana Agric. Exp. Stat., Baton Rouge.]

The daily Ca intake, excretion and retention were estimated in 6 healthy pre-adolescent girls, 8-year-old twins, two 9-year-old girls and 2 sisters aged 8 and 11, during a 56-day experiment. The experiment consisted of 9 collection periods: periods 1 to 3 formed the first basal period, 4 and 5 the first experimental period, 6 and 7 the second basal period and 8 and 9 the second experimental period. The first period was used for adjustment and analytical values were not included. During the first basal period the subjects received a milk-free diet devoid of vitamin A and carotene which met the U.S. National Research Council recommendations (Abst. 3538, Vol. 24) for energy, protein, Fe, nicotinic acid and ascorbic acid; supplements of vitamin B_1 hydrochloride, riboflavin and Ca in the form of calcium lactate were given to meet the recommended allowances. As the study was designed to investigate the utilisation of carotene from sweet potatoes by girls on diets with and without fat-free milk, the sources of fat were controlled and no carotene or vitamins A or D were included. In the first experimental period 3600 μg. carotene as sweet potato was added to the basal diet. For these 2 periods 3 subjects received reconstituted non-fat dried milk as a daily source of 1 g.

Ca and the other 3 subjects received calcium lactate. The plan for the second basal and experimental periods was identical with the first, but the groups of 3 subjects were reversed. During the basal period 3 menus were rotated; 2 were modified by adding sweet potatoes and non-fat dried milk solids and given alternately during the experimental periods. The menus were isocaloric and equal in N content and in fat content. Weighed amounts of fondant were allowed to appetite; the 11-year-old girl was allowed extra meat.

The daily mean intake of Ca was 0·85 g.; 5 of the 6 subjects were in negative Ca balance. More Ca was excreted when Ca was supplied as lactate than when it was provided by dried milk. The daily mean urinary Ca excretion ranged from 0·078 to 0·163 g. and accounted for 9·2 to 19·2 per cent. of the intake. The urinary excretion was relatively constant for each subject. The daily mean faecal Ca excretion ranged from 0·726 to 0·848 g., representing from 85·8 to 99·9 per cent. of the intake. This resulted in a daily mean loss of 0·068 g. Ca for 5 of the subjects, with loss ranging from 0·110 to 0·033 g. The 11-year-old subject retained 0·020 g. The retention of all the subjects appeared to increase when dried milk was added to the diet. This addition also increased the calculated P intake from a mean of 0·49 g. to 1·12. The increase in the P intake to a 1 : 1 ratio with Ca was stated to be the main cause of the apparent improvement in Ca retention.—G. F. Garton.

BRINE, C. L. and JOHNSTON, F. A. **Endogenous calcium in the feces of adult man and the amount of calcium absorbed from food.** *Amer. J. Clin. Nutrit.*, 1955, **3**, 418–420. [New York State Coll. Home Econ., Cornell Univ., Ithaca.]

Faecal excretion of Ca was plotted against Ca intake and the curve was extrapolated to zero to give an estimate of endogenous Ca. On the basis of data from 51 published reports the estimate of endogenous Ca was 75 mg. daily. The data on Ca intake less Ca excretion were then corrected for endogenous Ca to give the amounts of Ca absorbed. At intakes of 400 to 599 mg. daily the percentage absorbed was 43, at intakes of 600 to 999 mg. 34 to 35 and at intakes of 1000 to 1199 mg. 28.—F. C. Aitken.

BRONNER, F., HARRIS, R. S., MALETSKOS, C. J. and BENDA, C. E. **Studies in calcium metabolism. The fate of intravenously injected radiocalcium in human beings.** *J. Clin. Invest.*, 1956, **35**, 78–88. [Dept. Food Technol., Massachusetts Inst. Technol., Cambridge, Mass.]

Nine adolescent boys were studied for 5 days and one young man was studied for 60 days after an injection of ^{45}Ca. The estimated rate of disappearance for serum Ca in the boys was about 19 per cent. per min. The average percentage of injected ^{45}Ca excreted in urine and faeces in 5 days did not exceed 8 in the boys and was 20 in the young adult. At the end of 60 days the young man had excreted 40 per cent. of the injected ^{45}Ca. The amounts excreted in urine were 1·5 to 2 times the amounts excreted in faeces.

MACDONALD, W. B. and STAPLETON, T. **Idiopathic hypercalcaemia of infancy. Studies of the mineral balance.** *Acta paediat.*, 1955, **44**, 559–578. [Paediat. Unit, St. Mary's Hosp. Med. Sch., London.] French, German and Spanish summaries.

Three cases of idiopathic hypercalcaemia are reported. In 2, Ca, P and Mg balances were studied while the diet was cow's milk or dried cow's milk without added vitamin D, a therapeutic diet of Ca-free milk followed by a therapeutic diet of Ca-free milk and Ca-free cereal rich in phytic acid and finally a mixed diet with cow's milk. In the third child balance studies were not made; this patient refused the cereal of the second therapeutic diet. In all 3, estimations were made of serum Ca, P, Mg, proteins, cholesterol, blood urea and alkaline phosphatase. Each patient was treated with cortisone for 2 to 4 weeks during the study. Ca-free milk, and to a greater extent Ca-free milk with Ca-free cereal, converted positive Ca balances to negative balances, and both diets reduced serum Ca. Cortisone also reduced serum Ca and caused negative Ca balances. No significant change was observed in Mg and P balances during treatment. Treatment which reduced serum Ca also brought down serum P and blood urea.

SCHLESINGER, B. E., BUTLER, N. R. and BLACK, J. A. **Severe type of infantile hypercalcaemia.** *Brit. Med. J.*, 1956, i, 127–134. [Hosp. Sick Child, Gt. Ormond St., London.]

The findings in 3 more children with severe infantile hypercalcaemia, 2 of whom died, and the information supplied by groups of physicians who together have had 7 others in their care are summarised and discussed. In addition to the high blood Ca the amounts of urea and cholesterol in the blood were often above normal, and an abnormal facies, retardation of both physical and mental growth and osteosclerosis were the common physical signs. The cause remains unknown. Treatment suggested is by diet free from vitamin D and including low-calcium milk, which is now available in Britain.—D. Harvey.

3346

SPENCER, H., BROTHERS, M., BERGER, E., HART, H. E. and LASZLO, D. **Strontium^{85} metabolism in man and effect of calcium on strontium excretion.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 155–157. [Div. Neoplastic Dis., Montefiore Hosp., New York.]

^{85}Sr was injected intravenously into 4 human subjects at 0·1 to 0·4 μC. per kg. bodyweight, and the rates of excretion in urine and faeces were studied.

In a 72-year-old woman the study continued for 16 days, by which time 34·5 per cent. of the dose had been excreted in urine and 16·3 per cent. in faeces.

When a second injection was given at the mid-point of a 2-hr. infusion of calcium gluconate the renal clearance of Sr increased; 5 to 15 times as much Sr was found in the hour after injection as in the absence of treatment.—R. Hill.

3348

BAUER, G. C. H., CARLSSON, A. and LINDQUIST, B. **A comparative study on the metabolism of Sr^{90} and Ca^{15}.** *Acta physiol. scand.*, 1955, **35,** 56–66. [Dept. Pharmacol., Univ. Lund.]

Two-month-old rats, fed on a stock diet, were killed at intervals ranging from 15 min. to 48 hr. after an intraperitoneal injection containing 15 μC. ^{45}Ca and 0·25 μC. ^{90}Sr. Retention in the body and uptake by the skeleton of radio-active Ca and Sr were studied.

The losses of ^{90}Sr were greater in faeces and urine than those of ^{45}Ca, and the retention of Sr was less than the retention of Ca. But the accretion and exchange of ^{90}Sr in the skeleton were similar, relative to the dose given, to the accretion and exchange of ^{45}Ca.—R. Hill.

3349

BAUER, G. C. H., CARLSSON, A. and LINDQUIST, B. **Some properties of the exchangeable bone calcium.** *Acta physiol. scand.*, 1955, **35,** 67–72. [Dept. Pharmacol., Univ. Lund.]

The specific activities of serum Ca and the exchangeable fraction of bone Ca after an injection of ^{45}Ca (see preceding Abst.) indicated that the exchangeable fraction of bone Ca is not uniform. It is suggested that there are probably a large number of fractions which exchange Ca at different rates, attaining the specific activity of blood at intervals up to about 8 hr. after injection.—R. Hill.

3350

ALEXANDER, G. V., NUSBAUM, R. E. and MACDONALD, N. S. **The relative retention of strontium and calcium in bone tissue.** *J. Biol. Chem.*, 1956, **218,** 911–919. [Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

The femurs of rabbits, rats and mice of different ages which had been fed on stock diets were ashed and Ca and Sr were estimated in the ash. The ratio of Sr to Ca in animals given the same diet was relatively constant for a particular species over a wide age range.

Sr and Ca were estimated in the diets and the ratios in diet and bone were compared. They indicated preferential utilisation of Ca in bone metabolism. In animals allowed to reach equilibrium on a particular diet the Sr : Ca ratio of the bone ash would apparently be between 0·15 and 0·40 of the ratio in its diet.

There were species differences in retention of Sr, but it is suggested that for a given species it may be possible to predict retention in the skeleton from a knowledge of the Sr : Ca ratio of the diet.

R. Hill.

3351

MACDONALD, N. S., SPAIN, P. C., EZMIRLIAN, F. and ROUNDS, D. E. **The effects of calcium and phosphate in foods on radiostrontium accumulation.** *J. Nutrition*, 1955, **57,** 555–563. [Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

The incorporation of ^{90}Sr in equilibrium with ^{90}Y into the femurs of rats after it was given by mouth was reduced when the diet contained much Ca. This reduction was even more pronounced when the P intake was also high. It is suggested that the inhibitory effect of Ca is related to the metabolic dilution of ^{90}Sr with total alkaline earth ions, and that the effect of phosphate is probably due to precipitation of ^{90}Sr ions in the intestine. Anomalous results were obtained with dried milk powder, which did not significantly reduce accumulation of ^{90}Sr. In preliminary experiments ethylenediamine tetra-acetic acid given by mouth increased the accumulation of ^{90}Sr in the femur.

KUMAMOTO, Y. and LEBLOND, C. P. **Radioautographic study of mineralization of growing teeth with labeled calcium.** *J. Dent. Res.*, 1956, **35,** 147–156. [Dept. Anat., McGill Univ., Montreal.]

Young rats were given an injection containing 1 μC. radio-active Ca either on the day of birth or 3 days later. Two animals which received this injection 3 days after birth were given another injection 6 days after birth. Rats were killed at intervals up to 9 days after birth, sections were cut or ground and radio-autographs were prepared.

There was no great difference between the results from rats injected at birth and those injected 3 days after birth. The dentine of sections from rats killed 1 hr. after injection was radio-active in the region adjacent to the predentine, and in rats killed later this radio-active band was further from the predentine owing to the secretion of new non-radio-active dentine. The rate of formation of dentine, measured on sections of animals given 2 injections, was about 18 μ. daily.

No similar pattern of deposition of radio-active Ca was found in enamel, where radio-activity was more diffuse than in dentine. Ca appeared to be deposited as readily in enamel formed before the injection was given as in enamel formed just after the injection.—R. Hill.

3354

TROITSKII, N. A. Dermografizm i elektrochustivitelnost pri mineralnoi nedostatochnosti v organizmakh sviniei. [**Dermographism and sensitivity to electrical stimuli of pigs with mineral deficiency.**] *Veterinariya*, 1955, **32**, No. 10, 62–64. [Smolensk. Vet. Inst.]

Early stages of mineral deficiency are said to be characterised by delayed reflexes, low muscle tone, increased action of the sympathetic and diminished action of the parasympathetic nervous system. Dermographism and changes of sensitivity to electrical stimuli were tried as methods of early diagnosis.

Normal dermographism was studied on 32 healthy pigs 3 to 8 months old. A dermograph, spring-loaded to ensure constant pressure, was drawn over the chest. In 15 animals, with a latent period of 0·5 to 3·5 min. after drawing there appeared a faint red line visible for 0·4 to 3 min. In the other 17 pigs the red line was preceded by a faint white line. Clinical and biochemical tests of Ca and P status showed no deviation from normal. To study sensitivity to electrical stimuli galvanic current was used. The anode was in contact with the breastbone, and the cathode, in the form of a metal tube filled with damp cotton-wool, was in contact with the ulna. The current was increased by steps until there was a quick flexion of the wrist. In healthy pigs this threshold was 8 to 9 milliamps. Another 156 pigs were kept on a potato diet deficient in vitamin D and containing an excess of P. In winter, after 2 to $2\frac{1}{2}$ months, a change in dermographism was found in 85 out of 156 pigs; the latent period was shorter, 10 to 40 sec., and instead of the faint red line a very distinct white line appeared for 5 to 20 sec. and changed to a bluish-red line vanishing after 3 to 5 min. X-rays showed no bone disorder, but serum Ca was only 6 to 8 mg. per 100 ml. and P as high as 10 or 12 mg. In 82 per cent. of the pigs the sensitivity to electrical stimuli increased proportionally with changes in the blood. With Ca at 7 to 8 mg. per 100 ml. and below, the galvanic threshold was reduced to 4 to 5 milliamps. or less.

Large doses of vitamin D, 300,000 to 400,000 I.U., and change of diet arrested the development of mineral deficiency. Dermographism and electrical sensitivity returned to normal.

It is concluded that a white changing to bluish-red dermographism and increased sensitivity to electrical stimuli indicate a change of balance between Ca and P in the blood and thus help early diagnosis of mineral deficiency.—F. Billewicz.

VALETTE, G. and CALDERON, C. E. Effet de la teneur du régime alimentaire en calcium sur la sensibilité du cobaye à l'histamine. [**Effect of the calcium content of the ration on histamine sensitivity in the guineapig.**] *C.R. Acad. Sci.*, 1956, **242**, 1228–1230.

For previous work see Abst. 2067, Vol. 26.

Groups of 5, 8 and 7 guineapigs were given a normal diet alone or with 100 mg. calcium gluconate, or a diet poor in Ca, during the 8 days before the start of experiment. The animals were anaesthetised and given, by jugular vein, 0·2 mg. per ml. histamine hydrochloride at the rate of 0·5 ml. per min. The injection was continued until the animal died and the volume of solution injected into the animal at the moment of cardiac failure was noted. In a similar experiment on 7 groups, each of 10 guineapigs, the histamine hydrochloride solution was administered by stomach tube; the same quantity per kg. bodyweight was given to all the animals of each group, the percentage of animals which died being noted. Three groups received the normal diet, 2 the high-Ca and 2 the low-Ca diet.

In both experiments animals which received the high-Ca diet acquired resistance to the toxic effects of histamine and those on low-Ca diets were more sensitive to histamine toxicity.—G. F. Garton.

WRIGHT, E. **The uptake of phosphorus by the sheep. 1. The excretion of injected radio-phosphorus. 2. The availability of the phosphorus of a diet of hay and concentrates.** *N.Z. J. Sci. Technol.* [*A*], 1955, **37**, 332–348. [Animal Res. Stat., Dept. Agric., Wallaceville.]

1. Romney ewes and one crossbred Romney wether were fed once daily on 1 kg. chaffed ryegrass and clovery hay and 250 g. "sheepnuts".

Urine and faeces were collected separately. Orthophosphate labelled with ^{32}P was given intravenously, the 4 sheep receiving, respectively, 1, 2, 10 and 10 mC. Excretion of ^{32}P is shown in tables and graphs.

Faecal output of ^{32}P showed a diurnal rhythm in all 4 sheep, with greater excretion by day than by night. The diurnal rhythm sometimes appeared also in urine, but in one sheep the nocturnal excretion exceeded the diurnal for 3 consecutive days. There was a variable time lag between peaks of excretion in urine and in faeces, and the specific activity of the urine could be used in the estimation of endogenous faecal P.

2. By similar methods it was found that in 2 sheep the percentage of dietary P absorbed varied widely from day to day, with extremes of 32 to 78 in one sheep and 63 to 100 in the other. There was a significant positive correlation between the amount of P absorbed on a given day and the P balance; hence under the experimental conditions balance was thought to be determined by absorption and not by excretion.—D. Duncan.

SCHREIER, K. and NÖLLER, H. G. Stoffwechselversuche mit verschiedenen markierten Polyphosphaten. [**Metabolism experiments with some labelled polyphosphates.**] *Arch. exp. Pathol. Pharmakol.*, 1955, **227**, 199–209. [Kinderklin., Univ. Heidelberg.]

The 4 sodium polyphosphates which were labelled with ^{32}P were pyrophosphate, $Na_4P_2O_7$; tripolyphosphate, $Na_5P_3O_{10} . 6H_2O$; a polyphosphate with 62 per cent. P_2O_5, called polyphosphate 62; and hexametaphosphate or Graham salt. Each was given to rats in a dose of 30 mg. in 1 g. skimmed milk cheese and 3 ml. skimmed milk by stomach tube. After 12 to 24 hr. the rats were killed by bleeding and ^{32}P was estimated in liver, digestive tract, brain and the long bones of the right hind leg, and also in blood fractions.

All the salts were absorbed and utilised, Graham salt least. It appeared that the other 3 salts were mostly hydrolysed in the intestine and absorbed as orthophosphate. Bacteria from rat intestine incorporated the labelled polyphosphates and also broke them down to orthophosphate.—D. Duncan.

CORSA, L. (Jr.), GRIBETZ, D., COOK, C. D. and TALBOT, N. B. **Total body exchangeable water, sodium and potassium in "hospital normal" infants and children.** *Pediatrics*, 1956, **17**, 184–191. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.] Spanish and Interlingua summaries.

New data, obtained in a study of 18 children, are tabulated. Graphical presentation of these observations, together with data from the literature, shows high levels of exchangeable water and Na in young infants, decreasing towards adult level during the first 2 years of life, and a fairly uniform level of exchangeable K at all ages. Estimations of cell K concentration show little change with age.—F. C. Aitken.

3359

STAPLETON, T. **The pattern of the electrolyte excretion in the urine of babies born to diabetic mothers.** *Arch. Dis. Childhood*, 1956, **31**, 42–43. [Paediat. Unit, St. Mary's Hosp. Med. Sch., London.]

Urinary excretion of Na, K and Cl during the first 3 days of life, expressed as m. equiv. per kg. of the lowest weight during the first 3 days, was within normal limits in 5 babies born to diabetic mothers.—F. C. Aitken.

3360

DENTON, D. A. **The effect of Na^+ depletion on the $Na^+ : K^+$ ratio of the parotid saliva of the sheep.** *J. Physiol.*, 1956, **131**, 516–525. [Dept. Physiol., Univ. Melbourne.]

The volume of saliva secreted from one parotid gland of the sheep changed with the feed even though the Na intake was constant. This may be related to the length of time spent in rumination. The volume and composition of saliva were sensitive to sodium depletion. If the Na lost in the saliva was not replaced the volume secreted rapidly decreased and its Na content was reduced and partly replaced by K. The P content of the saliva also increased. Increasing the Na intake above normal by giving $NaHCO_3$ caused a decrease in the volume of saliva and an increased concentration of Na.—A. T. Phillipson.

HOLLAND, W. C. and AUDITORE, G. V. **Distribution of potassium in liver, kidney and brain of the rat and guinea pig.** *Amer. J. Physiol.*, 1955, **183**, 309–313. [Dept. Pharmacol., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

The distribution of K in liver, kidney and brain of young adult guineapigs and albino rats was

studied by flame photometry. About 65 to 80 per cent. of the tissue K was in solution in the cytoplasm and 12 to 13 per cent. was in the mitochondria, except that in the brain 30 per cent. or more of the total K was in the mitochondrial fraction. No K was detected in the microsomal fraction.

It is suggested that the K present in the mitochondria may be the slowly exchanging or non-exchangeable fraction found in studies on the uptake of radio-active K by the brain and kidney.

WESTERINK, D., OFFERIJNS, F. G. J. and WILLEBRANDS, A. F. De invloed van kaliumdeficiëntie op het gehalte aan water en electrolyten in serum en spierweefsel bij de rat. [**Effect of deficiency of potassium on the water and electrolyte content of serum and muscle in the rat.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99,** 3342–3348. [2 Klin. Inw. Ziekten, Wilhelmina Gasthuis, Amsterdam.] English summary.

The experimental diet contained, in g. per kg., sugar 725, vitamin-free casein 180, oil 50, minerals 40 and cod liver oil 5. The mineral mixture contained no K. A mixture of vitamins of the B complex was given. One group of rats weighing 60 to 90 g. received this diet alone, the other group had 3·35 g. K_2HPO_4 per kg. diet. The low-K diet contained less than 0·1 m. equiv. K per 100 g. After 21 or more days on these diets the rats were decapitated and blood was collected and samples of muscle were obtained. Water and electrolytes were estimated.

The rats deprived of K had in comparison with those given K significantly less serum K and Cl, 3·95 and 94 m. equiv. per kg. water compared with 7·15 and 118 m. equiv. The water content of muscle was not significantly increased, but the proportion of extracellular water was increased. Muscle Na was increased from 22·5 to 50 m. equiv. per kg. fat-free muscle, extracellular Na from 19·5 to 26·5 and intracellular from 3 to 24·5. Muscle K had fallen from 104·5 to 68 m. equiv. per kg.; almost all of it was intracellular in both groups. Muscle chloride was unchanged. Intracellular fluid was estimated to contain 41·5 m. equiv. Na and 112·5 m. equiv. K per kg. water in the deprived rats and 5 and 163 m. equiv. in those given K.

TALEISNIK, S. Régénération hépatique chez les rats soumis à des diètes sans potassium. [**Liver regeneration in the rat on potassium-free diets.**] *C.R. Soc. Biol.*, 1955, **149,** 1659–1660. [Inst. Recherches Méd., Mercedes et Martin Ferreyra, Cordoba.]

After removal of two-thirds of the liver 15 rats received a diet deficient in K and 18 rats received the same diet plus KCl for 10 days. Both groups regenerated liver equally well and the lipid and water contents of the liver were the same. The rats not receiving K gained less bodyweight and had less protein in the liver than the others.

SCHLESINGER, E. R., OVERTON, D. E. and CHASE, H. C. **Study of children drinking fluoridated and nonfluoridated water : quantitative urinary excretion of albumin and formed products.** *J. Amer. Med. Assoc.*, 1956, **160,** 21–24. [New York State Dept. Health, Albany.]

Ten years after the start of fluoridation in Newburgh, overnight urine specimens were collected from a hundred 12-year-old boys from Newburgh and a hundred from Kingston, the control town. The urines did not differ significantly in sp. gr., *p*H, or content of albumin, red blood cells or casts.—A. M. Thomson.

3366

MUHLER, J. C. and WEDDLE, D. A. (with STEWART, J. O.) **Fluorine storage in rats receiving different fluorides in the drinking water at varying pH.** *J. Dent. Res.*, 1955, **34,** 895–899. [Dept. Chem., Indiana Univ., Bloomington.]

In continuation of earlier work (Abst. 3899, Vol. 25), 4 groups of Sprague Dawley rats, over 220 in all, given a cariogenic maize diet (Abst. 5468, Vol. 20) from 30 days of age, had 20 μg. F per ml. drinking water as stannous fluoride, stannous chlorofluoride or sodium fluoride, or none, and sub-groups had the *p*H of the water adjusted to 2, 4 or 6 by addition of HCl or NaOH. Drinking water was restricted in amount to that taken by the least thirsty group. After 140 days the rats were killed, caries was evaluated and F was estimated in femurs.

There was some difficulty in distinguishing between caries and erosion by acid at *p*H 2, but all 3 fluorides were considered to reduce caries by at least 50 per cent. At *p*H 4 or 6 the tin fluorides were only about half as effective as at *p*H 2, and NaF was only half as effective as they were. It is stated that under the conditions of this experiment NaF and SnF_2 gave the same amount of F in the femur [Table 1, p. 897, seems to be faulty; some items omitted, others duplicated].

When rats in groups of 4 were given 2 mg. F daily for 14 days as a solution of NaF, sodium monofluorophosphate, SnF_2 or stannous chlorofluoride by stomach tube, the total amounts found

in the femurs and in the whole body did not greatly differ but the whole body contained less F when the monofluorophosphate or chlorofluoride was used. Only about half the F given was retained.—W. M. Deans.

3367

WEDDLE, D. A. and MUHLER, J. C. **Metabolism of small concentrations of fluorine in the albino rat.** *J. Dent. Res.*, 1955, **34,** 900–909. [Dept. Chem., Indiana Univ., Bloomington.]

Of groups of Sprague Dawley rats [number not stated], housed individually in stainless steel cages and given a stock diet of maize, F content 0·56 μg. per g., one had distilled water, F content 0·06 μg. per g., to 28 days of age and the other 50 μg. F per ml. drinking water as NaF from 14 to 28 days of age. Thereafter half of each group had distilled water and the other half 5 μg. F per ml. as NaF for 80 days, during which F in urine and faeces was estimated every 3 days by titration with thorium nitrate. The results are shown graphically.

Rats without F supplement (controls) retained $1{\cdot}5 \pm 0{\cdot}5$ μg. F daily. Those given F from 14 to 28 days, but not subsequently, lost F for 3 or 4 weeks, mainly in the urine, after F was stopped but then retained it at about the same rate as controls. Rate of storage of F relative to body-weight by rats given 5 μg. F per ml. decreased steadily with time whether they had had F earlier or not. The rate was higher for females than for males. Total F retained by those given 5 μg. F per ml. was a linear function of time, except at first for those who had had F earlier. The results for total F in the femur were consistent with those of the metabolic studies. About 35 per cent. of the F occurring naturally in the diet was retained; of that given as NaF, nearly twice as much.

3368

WEDDLE, D. A. and MUHLER, J. C. **Frequency of fluoride administration in relation to skeletal storage.** *J. Dent. Res.*, 1956, **35,** 65–68. [Dept. Chem., Indiana Univ., Bloomington.]

Comparable groups of rats were given drinking water containing NaF; one group had the water to appetite, and the others had the same amount as the first group by stomach tube, in one dose or in 3 equal parts daily. The first experiment lasted 20 and the second 40 days. At the end the rats were killed and F was estimated in teeth, bones and whole carcase. The F retained was calculated as a percentage of that ingested.

Most F was retained when it was given once a day, least when it was given 3 times a day. The results are discussed in relation to the problem of dental caries.—T. D. Bell.

JARRETT, I. G. and PACKHAM, A. **Response of the sheep to sublethal doses of fluoroacetate.** *Nature*, 1956, **177,** 580–581. [Div. Biochem. Gen. Nutrit., C.S.I.R.O., Univ. Adelaide.]

The concentration of citrate in the blood of sheep fed on chaffed wheat hay, or chaffed lucerne hay, or wheat hay with gluten was studied when sodium fluoroacetate, 2 mg. daily, was administered as a drench, by subcutaneous injection, as a drip into the abomasum or into the peritoneal cavity or the jugular vein. Sheep fed on wheat hay developed clinical signs of poisoning after all methods of administration. Death occurred after a few days in some and after 3 weeks in others. Substitution of lucerne for wheat hay towards the end of the 3 weeks resulted in recovery despite continued administration of fluoroacetate.

Sheep fed on lucerne hay showed no sign of poisoning in 45 days when fluoroacetate was given by drench or subcutaneous injection. Death occurred in 10 to 20 days without the characteristic syndrome seen in animals fed on wheat hay when fluoroacetate was given intravenously or directly into the abomasum. Sheep fed on wheat hay and gluten and drenched with or given subcutaneous injections of fluoroacetate showed no sign of poisoning in 45 days. No close correlation was found between clinical signs and citrate concentration in the blood. The effects of lucerne or a gluten supplement suggest that protein may protect the ruminant against sublethal doses of fluoroacetate.—J. C. Gill.

3370

MACAULAY, D. **Total body chloride and urinary chloride excretion in infants and children.** *Clin. Sci.*, 1955, **14,** 615–623. [Dept. Child Health, Univ. Manchester.]

Of the 46 children aged from 2 months to 13 years who were the subjects of study, 21 were normal and the others had some disease likely to affect salt and water metabolism. Sodium thiocyanate and T 1824 were given intravenously and thiocyanate space and dye space were estimated. Serum Cl and 24-hr. output of Cl in urine were estimated also. Total body Cl and total plasma Cl were computed, respectively, by multiplying thiocyanate space and dye space by serum Cl concentration.

In normal children total body Cl per kg. body-weight was greater for infants under 6 months than for children over 2 years, but the fraction of total body Cl excreted in a day in urine was the same for both age groups. Dye space and thiocyanate space were highly correlated in normal but not in abnormal children, and it is suggested that total plasma Cl is not always a good measure of total body Cl. Variation from normal in the

ratio of urinary Cl to total body Cl in children with obesity, diabetes, nephrosis and tuberculous meningitis and after surgery are discussed.

3371

GERBAULET, K. and FITTING, W. Über das Jod-Konzentrierungs- und -Sekretionsvermögen der Speicheldrüsen. (Untersucht mit Jod^{131} bei Patienten mit unterschiedlicher Schilddrüsenfunktion). [**Capacity of the salivary glands to concentrate and secrete iodine, investigated with ^{131}iodine in patients having different degrees of thyroid activity.**] *Klin. Wochenschr.*, 1956, **34**, 120–125. [Med. Klin., Univ. Cologne.]

The ^{131}I activity in serum, saliva and thyroid was estimated after a test dose of 150 μC. $Na^{131}I$ given intravenously to 5 patients with normal thyroid function, 2 with slight and 4 with severe hyperthyroidism, and one with myxoedema.

In the normal subjects the ^{131}I activity of the saliva fell from $3{\cdot}35 \times 10^{-1}$ per cent. of the test dose 4 min. after the injection to 6×10^{-4} per cent. 24 hr. later. The radio-activity of the serum fell on a curve similar to that of the saliva but at a lower level.

In the hyperthyroid patients the values in both saliva and serum immediately after the test dose were about the same as in normal patients, but the values then fell much more steeply; in the saliva the minimum value was reached in about 7 hr. and in the serum in 90 min., but the minimum in the serum was not as low as in normal subjects. Later the radio-activity of the serum rose above that of the saliva. Separate estimations of the radio-activity of the organic I in the serum showed that it rose steadily from a very low level to become almost equal to the total radio-activity in the serum about 8 hr. after the test dose.

In the patient with myxoedema the curves for radio-activity in saliva and serum were like those of the normal subjects but flatter.

The ratio salivary ^{131}I per ml. : serum ^{131}I per ml. was estimated at intervals from immediately after the test dose when the values were maximum, to 24 hr. after it, when the minimum values occurred. The maximum and minimum values of the ratio for normal, hyperthyroid and hypothyroid patients were, respectively, 40 and 8, 141 and 0·5, and 63 and 55. The maximum value was taken as an index of the capacity of the salivary glands to concentrate iodine. The uptake of ^{131}I by the thyroid rose in the normal subjects to about 40 per cent. of the amount given in about 8 hr., and continued to rise very slowly during the next 16 hr., but in the hyperthyroid patients the rise was steeper and reached 75 per cent. of the amount given in about 3 hr. The radio-activity of the gland then fell gradually to about 50 per cent. of the amount given, 21 hr. later.

Electrophoretic studies showed that only about from 10 to 15 per cent. of the total ^{131}I activity in the saliva was organically bound even after 19 hr. In the serum, on the other hand, the percentage organically bound immediately after the injection was only 5, but after 19 hr. it was more than 99.

VAN MIDDLESWORTH, L. **A method for iodide balance studies in animals on low iodide diets.** *Endocrinology*, 1956, **58**, 235–242. [Dept. Physiol., Univ. Tennessee, Memphis.]

Adult male rats were maintained for 4 to 6 months on a goitrogenic diet containing 0·015 μg. I per g. The rats utilised so little iodide that chemical methods for estimation of faecal and urinary iodide and plasma protein-bound iodine (PBI) were unsatisfactory. The rats were therefore given a diet made by adding a solution of ^{131}I to each rat's measured daily ration until the rats were excreting the same amount of ^{131}I as they were ingesting. About 80 per cent. of the intake was excreted in faeces and 10 per cent. in urine and this happened whether the ^{131}I was given orally or intraperitoneally. In 5 experiments it was found that invariably most of the ^{131}I was excreted in faeces unless thyroid metabolism was disturbed, and then most of the ^{131}I was excreted in urine; thyroidectomised rats excreted 60 to 80 per cent. of the daily dose in urine and only 10 per cent. in faeces. The addition of thyroxine to the diet also increased output of ^{131}I in urine and diminished that in faeces. The addition of triiodothyronine brought the rats into positive balance; within 2 days faecal ^{131}I was less than that in urine and the positive balance persisted until 5 days after the triiodothyronine was discontinued. When 8 mg. propylthiouracil was added to the diet, ^{131}I in urine during the next 2 days was enormously increased and that in faeces was reduced to about 10 per cent. The ^{131}I balance became negative and did not become positive until 14 days after withdrawal of the drug.

It is claimed that by this method I balance, re-used iodide, functional total pool of thyroid and body I, plasma PBI and plasma iodide can be studied.—B. W. Simpson.

3373

BROWN, J. **Extra-thyroidal iodide metabolism in the rat.** *Endocrinology*, 1956, **58**, 68–78. [Ziskind Res. Labs., New England Centre Hosp., Boston, Mass.]

Adult male rats fed on Purina chow were used for all the experiments. For studies on distribution of iodide, administration of propylthiouracil was followed by injection of 10 μC. of ^{131}I. Thereafter tail blood samples were taken at intervals for estimation of radio-activity. For salivary and

gastric studies, propylthiouracil was administered and a catheter was sutured to the duodenum in such a way that the contents of the stomach could be collected. ^{131}I was injected subcutaneously. Urine and tail blood were collected and analysed. To identify the chemical state of the ^{131}I secreted in the stomach, thyroids were removed, thyroxine and ^{131}I were injected and the gastric contents were collected by catheter as before and analysed. Only iodides were found in the gastric juices. In studies on the kidney, thyroids were removed, thyroxine and ^{131}I were administered and urine and tail blood samples were examined. One week later the study was repeated on the same animals in the same way after injection of propylthiouracil.

The space of distribution of ^{131}I was 50 per cent. of the bodyweight. Treatment with KCNS reduced the space to 40 per cent. of the bodyweight by reducing the secretion of iodide into the digestive tract from 71 to 56 per cent. of the dose administered. Treatment with propylthiouracil did not alter the space of distribution, but the loss of ^{131}I from the blood was accelerated and clearance of iodide by the kidneys was substantially increased. Thyrotropin did not stimulate secretion of iodide in the saliva or by gastric glands. When chloride was given there was a significantly greater iodide clearance rate. Combined salivary and gastric secretion of ^{131}I contained 71 per cent. of the injected tracer. The combined salivary and gastric clearance rate was 4 to 5 times the renal clearance rate. Removal of the salivary glands reduced the total ^{131}I collected from 71 to 61 per cent., *i.e.*, saliva contributed one-fifth to the stomach contents.

The results of this study confirm those of previous workers. The implications of the increase of renal clearance rate by propylthiouracil are discussed.—B. W. Simpson.

3374

VERZÁR, F. and FREYDBERG, V. **Changes of thyroid activity in the rat in old age.** *J. Gerontol.*, 1956, **11,** 53–57. [Physiol. Lab., Univ. Basle.]

Rats, 32 aged 20 to 29 months and 30 aged 7 to 9 months, were injected intraperitoneally with 25 μC. of ^{131}I without carrier, dissolved in 0·25 ml. physiological saline. The thyroids were tested for radioactivity 18 to 24 hr. later and thereafter at $2\frac{1}{2}$, $5\frac{1}{2}$ and $7\frac{1}{2}$ days. The rats were anaesthetised during the measurements of radio-activity. In a number of both old and young rats excretion of ^{131}I in the urine was measured.

Uptakes of ^{131}I were higher in 84 per cent. of the old animals on the 5th and 7th days than in the young. The release of ^{131}I was slower in the old than in the young. The renal excretion of ^{131}I on the first day after injection was on the average 29·2 per cent. of the dose in the old rats and 48·4 per cent. in the young. The slow release of ^{131}I from the thyroids of the older rats may have caused the low excretion of ^{131}I in urine.

B. W. Simpson.

3375

VAN MIDDLESWORTH, L. **Effect of casein on iodide metabolism.** *Endocrinology,* 1956, **58,** 109–113. [Dept. Physiol., Univ. Tennessee, Memphis.]

Rats were fed from weaning on a goitrogenic diet labelled with ^{131}I. They were kept in metabolism cages and their excreta were collected and analysed daily. After these rats reached I equilibrium, a purified casein, free from inorganic iodide and with only a trace of organic iodide, was incorporated in the diet. Faecal iodide decreased and a positive I balance resulted. Twenty days after the removal of the purified casein from the diet of another group which had been fed on the purified casein from weaning, urinary and faecal ^{131}I were the same as in the first group before the purified casein was added. It is suggested that digestion of the purified casein produced a compound which effectively inhibited thyroid hypertrophy.—B. W. Simpson.

JENSEN, W. N., BUSH, J. A., ASHENBRUCKER, H., CARTWRIGHT, G. E. and WINTROBE, M. M. **The kinetics of iron metabolism in normal growing swine.**

BUSH, J. A., JENSEN, W. N., ASHENBRUCKER, H., CARTWRIGHT, G. E. and WINTROBE, M. M. **The kinetics of iron metabolism in swine with various experimentally induced anemias.** *J. Exp. Med.*, 1956, **103,** 145–159; 161–171. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

(a) Growing pigs were given injections of ^{59}Fe, and blood samples were taken at intervals after injection. The maximum incorporation of radioactive Fe into red cells, found about 5 days after injection, was 92 per cent. of the amount injected. The rate of incorporation was 1·01 mg. per kg. daily, but it was estimated that of this 0·42 mg. per kg. was due to growth, giving a red cell turnover rate of 0·59 mg. per kg. daily. The average "apparent" life span of red cells was 63 days.

(b) Pigs were made anaemic either by phenylhydrazine in the diet, or by deprivation of pyridoxine or folic acid, and Fe metabolism was studied.

Phenylhydrazine reduced the survival time of red cells to 5 days, but this was partly compensated by increased rate of formation, as indicated by increased incorporation of ^{59}Fe into red cells, which reached about 4 times the normal rate.

Pyridoxine deficiency did not affect the survival time of red cells, but formation was reduced to about one-quarter of the normal rate.

Folic acid deficiency reduced the survival time of red cells to 17 days, and although rate of formation increased, the increase was not enough to compensate completely for the reduced life of the cells.—R. Hill.

3378

STURZENEGGER, E. Enterale Eisenaufnahme bei Ratten mit experimenteller cholostatischer Lebercirrhose. [**Intestinal absorption of iron by rats with experimental liver cirrhosis with retention of bile.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 460–470. [Pathol. Inst., Univ. Zürich.]

Of 18 survivors of 50 rats of both sexes in which the bile duct was ligated, 10 received a normal diet and 8 the same with an admixture of 2 per cent. powdered ferric citrate. They were killed at intervals between the 20th and 60th days and the presence of Fe in organs was tested by the Turnbull's blue method.

The results were inconclusive, but since after 48 days traces of Fe were found in some liver cells of both groups, it was thought that the experiment was too short. Attempts will be made to combat the high mortality of the rats and speed up the deposition of Fe by using ferric Fe and a maize diet (cf. Abst. 892, Vol. 25).—W. M. Deans.

KASANEN, A. and VIITANEN, I. **On the copper content of the thyroid tissue and serum in thyrotoxicosis.** *Acta med. scand.*, 1956, **153,** 467–472. [Dept. Hyg., Univ. Turku.]

Estimation of the Cu content of thyroids was made in 30 toxic goitres, 8 non-toxic goitres, 19 healthy glands from children and 43 healthy glands from adults. Samples of serum from thyrotoxic patients and from healthy subjects were analysed at the same time.

The Cu content of the normal adult thyroids was $1{\cdot}775 \pm 0{\cdot}139$ mg. per 100 g. The toxic goitres contained $2{\cdot}226 \pm 0{\cdot}191$, the non-toxic goitres $2{\cdot}611 \pm 0{\cdot}480$ and the infantile thyroids $3{\cdot}055 \pm 0{\cdot}132$ mg. per 100 g. The serum Cu of 25 thyrotoxic patients was 0·130 and of 25 healthy subjects 0·133 mg. per cent.; there was no significant difference.

Serum Cu and thyroid function were not interdependent, a finding contrary to that of Narasaka (Abst. 4997, Vol. 8). No correlation between the Cu content of the thyroid and that of the liver nor between serum I and serum Cu was found, and treatment with Lugol's solution did not affect the Cu content of serum.—B. W. Simpson.

BUSH, J. A., MAHONEY, J. P., MARKOWITZ, H., GUBLER, C. J., CARTWRIGHT, G. E. and WINTROBE, M. M. **Studies on copper metabolism. 16. Radioactive copper studies in normal subjects and in patients with hepatolenticular degeneration.** *J. Clin. Invest.*, 1955, **34,** 1766–1778. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

For previous parts see Absts. 2095, 2096, Vol. 26.

One mg. Cu, in the form of radio-active cupric acetate of specific activity 0·8 to 1·2 mC. per mg. Cu, was given by mouth to 4 normal subjects and 4 patients with Wilson's disease and was injected intravenously into 4 normal subjects, 3 patients with Wilson's disease and 2 with alcoholic cirrhosis of the liver; the proportion of the ^{64}Cu excreted in the urine and faeces was estimated and the uptake of ^{64}Cu into the albumin and globulin fractions of plasma was studied. In 3 normal subjects, 4 patients with Wilson's disease and 2 patients with alcoholic cirrhosis of the liver the curve of disappearance of ^{64}Cu from the plasma after administration of 50 μg. ^{64}Cu was estimated. The uptake of ^{64}Cu by the liver was estimated in 2 normal subjects, 4 patients with hepatolenticular degeneration and 2 with alcoholic cirrhosis of the liver.

After administration of ^{64}Cu by mouth to normal subjects, on the average 0·1 per cent. was recovered in the urine and 72·4 per cent. in the faeces; in the patients with Wilson's disease, corresponding values were 2·5 and 52 per cent. The administration of K_2S with ^{64}Cu to 2 of the patients with hepatolenticular degeneration resulted in an increase in the amount of activity recovered in the faeces. After intravenous injection of ^{64}Cu in normal subjects, on the average 0·2 per cent. of the activity was recovered in the urine and 12·4 per cent. in the faeces; in the patients with Wilson's disease, 5·4 and 2·5 per cent., and in those with alcoholic cirrhosis 0·8 and 8·5 per cent.

The uptake of ^{64}Cu into plasma protein was impaired in patients with hepatolenticular degeneration, but not in patients with alcoholic cirrhosis. The uptake of ^{64}Cu by the liver was depressed in 3 of the 4 patients with hepatolenticular degeneration and in one with alcoholic cirrhosis. The uptake of ^{64}Cu by the red cells of patients with hepatolenticular degeneration was not different from the normal.—G. F. Garton.

CARTWRIGHT, G. E., GUBLER, C. J., BUSH, J. A. and WINTROBE, M. M. **Studies on copper metabolism. 17. Further observations on the anemia of copper deficiency in swine.** *Blood, J. Hematol.*, 1956, **11**, 143–153. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

Previous studies in this series showed that in pigs made Cu-deficient on a diet of milk supplemented with Fe the alterations in red cell and bone marrow morphology were indistinguishable from those in pigs deprived of Fe. This resemblance between the anaemias of Cu deficiency and Fe deficiency was not found by other workers who used dogs and a diet of milk supplemented with minerals and vitamins. The experiments with pigs were extended to include animals given supplements of minerals other than Cu and vitamins. Such supplements did not prevent, delay or modify the morphology of Cu-deficiency anaemia in pigs. An intravenous injection of Fe before the development of Cu deficiency did not prevent or delay the onset of anaemia.—F. C. Aitken.

3383

FOLLIS, R. H. (Jr.), BUSH, J. A., CARTWRIGHT, G. E. and WINTROBE, M. M. **Studies on copper metabolism. 18. Skeletal changes associated with copper deficiency in swine.** *Bull. Johns Hopkins Hosp.*, 1955, **97**, 405–414. [Dept. Pathol., Coll. Med., Univ. Utah, Salt Lake City.]

Two pigs receiving a Cu-deficient liquid milk diet supplemented with minerals, B vitamins and choline developed gross deformities of the legs. No skeletal defect was seen in 2 pigs receiving by mouth 0·5 mg. Cu per kg. bodyweight daily. Histological examination of the bones of Cu-deficient animals showed little osteoblastic activity and poor development of the bone cortex. The activity of chondroblasts appeared to be unaffected.

The similarity of these findings and those of earlier studies on Cu-deficient dogs (Abst. 852, Vol. 24) to the skeletal changes of ascorbic acid deficiency is emphasised.—C. F. Mills.

OTHER MINERALS

3384

HARTMAN, R. H., MATRONE, G. and WISE, G. H. **Effect of high dietary manganese on hemoglobin formation.** *J. Nutrition*, 1955, **57**, 429–439. [Animal Nutrit. Sect., Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

In 2 experiments young growing lambs were depleted of Fe either by a deficient diet or by a combination of the diet and periodic bleeding. In the first experiment 8 ewe and 8 wether lambs were given a diet of whole milk fortified with 50 p.p.m. Fe, 5 p.p.m. Cu and 0·1 p.p.m. Co on a dry matter basis, and vitamins A and D. In 4 experimental periods 3 groups, each of 2 ewe and 2 wether lambs, were given supplements of Mn of up to 5000 p.p.m. ; the supplements were increased gradually in successive periods. A level of 45 p.p.m. Mn reduced blood Hb and serum Fe ; higher levels of Mn gave lower Fe content of liver, spleen and kidney.

In the second experiment 8 anaemic lambs were given a basal diet of chopped soya bean hay 60, glucose 32, casein 4 and cottonseed oil 4 per cent. Three of the lambs received the basal diet alone, 3 the basal diet supplemented with 1000 p.p.m. Mn and 2 the basal diet with 2000 p.p.m. Mn. Hb regeneration was slow and serum Fe was low in both groups given Mn.

It is suggested that excess Mn either converts Fe to a form physiologically unavailable or in some manner antagonises the enzyme systems which oxidise or reduce Fe at the site of absorption.

G. F. Garton.

3385

NEHER, G. M., DOYLE, L. P., THRASHER, D. M. and PLUMLEE, M. P. **Radiographic and histopathological findings in the bones of swine deficient in manganese.** *Amer. J. Vet. Res.*, 1956, **17**, 121–128. [Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Three-week-old pigs were divided into 2 groups, one receiving a purified diet containing 0·5 p.p.m. of manganese and the other the same diet with manganese sulphate added to give 40 p.p.m. Mn.

There was no difference between groups in liveweight increase or efficiency of feed conversion, but Mn-deficient pigs had shorter and broader legs, and they appeared fatter than control pigs. The front legs of most Mn-deficient animals became bowed, causing lameness, owing apparently to early cessation of endochrondral ossification of the radius but normal ossification of the ulna. These signs of Mn deficiency, as well as generalised rarefaction of bones of the legs, were well developed 125 days after experimental feeding began, the stage at which some animals were killed. When

the experiment ceased after 335 days the Mn-deficient animals were no longer lame and the rarefied areas of bone observed radiologically and histologically at 125 days were no longer apparent, though other effects such as bowed front legs, short thick leg bones and increased deposits of fat persisted.—R. Hill.

GERSHOFF, S. N. **Biological effects of methionine sulfoximine. 2. Comparative sulfur metabolism studies in rats and rabbits.** *Amer. J. Physiol.*, 1956, **184,** 43–46. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

2. Rabbits excreted per unit bodyweight the same amount of sulphur as rats but 4 times as much of administered methionine. Rats had a greater concentration of S in liver, muscle and brain, but not spinal cord, than had rabbits. Rabbits were more prone to convulsions when given methionine sulphoximine. Methionine sulphoximine labelled with ^{35}S gave only small amounts of ^{35}S in the brains and spinal cords of both species after injection. Methionine sulphoximine given 1 hr. before injection of ^{35}S-methionine inhibited the uptake of ^{35}S in fed, but not in fasted, animals. Fasting partly protected rabbits against the toxicity of methionine sulphoximine.

CREMER, H. D. and DITTMANN, G. Einbau von organischem (Eiweiss-) und anorganischem (Sulfat-) Schwefel in Knorpel, Knochen und Zähnen. **[Incorporation of organic (protein) and inorganic (sulphate) sulphur into cartilage, bone and teeth.]** *Biochem. Ztschr.*, 1956, **327,** 377–382. [Physiol. Chem. Inst., Johannes Gutenberg Univ., Mainz.]

The method described in Abst. 2724, Vol. 26 was used to estimate chondroitin sulphate after paper electrophoresis of extracts of cartilage, bones and teeth; it was possible to detect, but not to estimate, protein and sulphate simultaneously with chondroitin sulphate. The technique was used in the following experiment.

A group of 5 young female rats weighing from 100 to 120 g. were each given an intraperitoneal injection of $Na_2{}^{35}SO_4$, 1 mC. in 0·5 ml., and a second group of 5 had 1 mC. of ^{35}S incorporated into yeast, mainly in the proteins and amino acids in their food. Three days later they were killed. Examination of the faeces in the interval showed that both groups retained roughly the same proportion, over half, of the radio-activity. Cartilage was extracted with 2 per cent. NaOH, bones and teeth with 10 per cent. Trilon (disodium ethylenediaminetetra-acetate). Protein, chondroitin sulphate and sulphate of cartilage, bone and teeth were all found to contain ^{35}S, even when it was given as inorganic sulphate. The activity of the protein was shown by paper chromatography to be associated with the sulphur amino acids cystine and methionine.

Incorporation of inorganic S is contrary to results in the literature. Reasons for the discrepancy are to be studied.—W. M. Deans.

3388

BINET, L. and WELLERS, G. La valeur physiologique des sulfates minéraux. **[Physiological value of mineral sulphates.]** *J. Physiol., Paris*, 1955, **47,** 883–892. [Lab. Physiol., Fac. Méd., Paris.]

The rate of growth was studied of young rats on a basal synthetic diet of casein, sugar, starch and lard with vitamins and a salt mixture without S, to which $Na_2SO_4 . 10H_2O$ was added at 0·06, 0·125, 0·25, 0·5, 1·0 and 2·5 per cent.; a control group had the diet without sulphate. Growth was best in the groups with 0·25 to 1·0 per cent.; at the 2 lowest levels the rate of growth differed little from that in the control group; at the highest level growth was considerably depressed after 9 days.

It is suggested that with the diet described, of which casein formed about 6 per cent., the mineral sulphate participated in the synthesis of mucopolysaccharides and, as a result, the organism could make more economical use of the sulphur amino acids which were likely to be deficient.

D. Harvey.

3389

KENT, P. W., JOWSEY, J., STEDDON, L. M., OLIVER, R. and VAUGHAN, J. **The deposition of ^{35}S in cortical bone.** *Biochem. J.*, 1956, **62,** 470–476. [Dept. Biochem., Nuffield Dept. Med., Univ. Oxford.]

Rabbits were given injections of $Na_2{}^{35}SO_4$. The site and form of deposition of ^{35}S were studied by measuring, by difference, the amount of ^{35}S removed during decalcification with ethylenediaminetetra-acetic acid, by analysis of the sulphated muco-substance extracted by KOH from the decalcified bone and by autoradiographic examination of thin sections. It was found in a labile form distributed throughout the bone and in a non-labile form concentrated in areas of active growth. There was evidence that the sulphur compound extracted from the decalcified bone was chondroitin or a substance closely related to it.

D. Harvey.

SANZ SANCHEZ, F. and ASTUDILLO, M. D. Estudio de la distribución del azufre en aves seguido por medio del radioazufre S-35, administrado en forma del sulfato sódico. **[Distribution of sulphur in birds studied with radio-active sulphur ^{35}S, given as sodium sulphate.]** *An.*

Inst. Invest. Vet., Madrid, 1954, **6**, 61–77. [Fac. Vet., Madrid.] English and German summaries.

Three groups of 6 chickens 8 to 9 months old were fed on a standard ration. In one group an artificial anus permitted separate collection of urine and faeces. These and a second group were kept in metabolism cages, the third group were at liberty and were laying pullets used to study elimination of S in the eggs. The ^{35}S was given by stomach tube or by intramuscular injection.

The birds with artificial anus, given ^{35}S by mouth, excreted 45 per cent. on the first day, 9·5 per cent. on the second, and on the sixth day 0·3 per cent. was recovered in the urine. When the S was given parenterally 49 to 50 per cent. was excreted on the first day, otherwise the pattern was similar. In 6 days the amounts recovered in the urine were 60 and 66 per cent. The amounts in the faeces on the first day were 13 and 7 per cent., according to the route of administration. The unoperated birds excreted less of the ^{35}S, 55 per cent. of the dose in 6 days.

In laying pullets the peak of radio-activity in the white of the eggs occurred on the first day after the injection, but in the yolk the activity increased to a peak on the fourth day. In the course of 7 days 3·0 and 3·2 per cent. of the injected dose was recovered from the whites and yolks, respectively.

The distribution of ^{35}S in tissues is tabulated.

D. Duncan.

ACID BASE EQUILIBRIUM

3391

De Langen, C. D. De zuur-basehuishouding bij de agastricus. [**Acid base metabolism after gastrectomy.**] *Nederland. Tijdschr. Geneesk.*, 1956, **100**, 246–247. [Utrecht.] English summary.

Part of the difficulties of subjects whose stomachs have been removed arise from disturbance of acid base metabolism. The normal cycle of Na from stomach via blood bicarbonate to digestive glands and the small intestine is broken. Regulation may be by temporary adsorption of Cl by collagen tissues. Since collagen decreases with age, this possible mechanism will function less efficiently and disturbances will increase.—I. Leitch.

METABOLISM OF WATER

3392

Bass, D. E. and Henschel, A. **Responses of body fluid compartments to heat and cold.** *Physiol. Rev.*, 1956, **36**, 128–144. [Environmental Protection Div., Quartermaster Res. and Development Centre, Natick, Mass.]

Weil, W. B. and Wallace, W. M. **Hypertonic dehydration in infancy.** *Pediatrics*, 1956, **17**, 171–183. [Dept. Paediat., Sch. Med., Western Reserve Univ., Cleveland, Ohio.] Spanish and Interlingua summaries.

Clinical observations and the electrolyte content of serum and urine are tabulated for 26 infants with serum Na levels of 160 m. equiv. or more per litre. Serum Cl was raised to a greater extent than was serum Na. Total CO_2 and *p*H were depressed. Na, K and Cl balance data were obtained in one patient during the development of hypertonic dehydration. Water loss was in excess of Na loss and Cl retention was considerable. In 4 patients balance data were obtained during recovery. In these, water balances were positive and Cl balances were negative. Na balance was slightly positive in 2.

Administration, at the rate of approximately 180 ml. per kg. bodyweight per 24 hr. of a solution containing 50 to 65 m. equiv. Na and 35 to 45 m. equiv. Cl per litre is the treatment recommended.

F. C. Aitken.

3394

Talso, P. J., Strub, I. H. and Kirsner, J. B. **The metabolism of water and electrolytes in patients with cirrhosis of the liver.** *J. Lab. Clin. Med.*, 1956, **47**, 210 – 226. [Dept. Med., Univ. Chicago, Ill.]

Balance studies were made during 4 periods in one normal subject and in 4 with liver cirrhosis with ascites and oedema. The only variation in diet was a reduction in salt intake, from 3·0 to 1·5 g. after the end of the second period. In the second and third periods 45 g. cation-exchange resin was given daily and in the fourth period a mercurial diuretic was given on alternate days.

The balance data were used to calculate shifts in body fluids. Bodyweight loss as a result of treatment of liver cirrhosis corresponded closely to loss of extracellular fluid. In patients with liver cirrhosis, biopsy samples of gastrocnemius muscle and deltoid muscle obtained before treatment contained more than the normal volume of

extracellular fluid. In gastronemius, which contained more fluid than deltoid muscle, extracellular fluid was reduced by treatment but remained above normal. There was no reduction of extracellular fluid in deltoid muscle.

It is concluded that oedema and ascites in liver cirrhosis represent isotonic expansion of extracellular fluid.—F. C. Aitken.

3395

MONTEMURRO, D. G. and STEVENSON, J. A. F. **The localization of hypothalamic structures in the rat influencing water consumption.** *Yale J. Biol. Med.*, 1955–56, **28**, 396–403. [Dept. Physiol., Univ. Western Ontario, London.]

Rats were maintained on a diet in which about 70 per cent. of the energy value was provided by sucrose, 10 per cent. by fat and the rest by casein. Mineral and vitamin requirements were met. Lesions were made in the hypothalamus with a stereotaxic instrument.

The greatest increase in food intake and the greatest obesity were produced by lesions in the ventromedial nuclei, and in these rats there was no increase in water intake. Rats with lesions in the lateral hypothalamic areas showed no increase in food intake, but drank less. They failed to increase their water intake when transferred to an environmental temperature of 35° C.—D. Duncan.

3396

HAIGH, C. P. and SCHNIEDEN, H. **Virtual deuterium oxide space (total body water) in normal and protein-deficient rats.** *J. Physiol.*, 1956, **131**, 377–382. [Res. Dept., Barrow Hosp., Bristol.]

The senior author's method of measuring deuterium (*Radioisotope Conference*, 1954, Vol. 2, p. 101, Butterworths Scientific Publications, London) was used for measurement under anaesthesia of total body water in 2 groups of rats, one on a normal diet and the other on a diet with 0·5 g. protein and providing 300 Cal. per 100 g. (Schnieden and Blackmore, *Brit. J. Nutrition*, 1956, in press). In some of the control animals both renal pedicles were ligated immediately before the injection of the D_2O.

In normal animals equilibrium was reached about 60 min. after injection and estimations made at that interval gave mean values, as percentage of bodyweight, of $70{\cdot}2 \pm 1{\cdot}7$ for 8 normal rats, $69{\cdot}9 \pm 1{\cdot}9$ for 6 " nephrectomised " and $80{\cdot}1 \pm 1{\cdot}2$ for 9 on the deficient diet. Oedema under such conditions of deficient feeding is concluded not to be the result of transference of fluid from intracellular to extracellular space.—D. Harvey.

3397

BURNS, T. W. (with BALEKJIAN, A.) **Endocrine factors in the water metabolism of the desert mammal, *G. gerbillus*.** *Endocrinology*, 1956, **58**, 243–254. [U.S. Naval Med. Res. Unit No. 3, Cairo.]

Gerbillus gerbillus, small desert rodents, were trapped near Cairo in summer and autumn. Adult males weighing from 17 to 25 g. were selected and housed at 21·8° C. and relative humidity 50 per cent. No water was given. The 4 diets used were pearled barley alone, or with carrots, or with salt, or soya beans alone. The water content of the cereals as given was 9 to 11 per cent. Droplets of urine were collected by pipette after spontaneous micturition had been produced by teasing the animals. Adrenals were removed from some animals under sodium pentobarbital anaesthesia.

In animals killed within 24 hr. after capture and in others fed on carrots and barley the urea concentration in urine was 1·32 and 1·12 *M*, and that of total electrolytes, expressed as NaCl, 0·617 and 0·476 equiv. per litre. Adrenals weighed 7·2 and 10·4 mg.

On salted barley the mean loss of bodyweight in 4 days was 37 per cent. and the mortality 10 out of 12; on soya beans the weight loss was 20 per cent. and mortality 4 out of 12. On the second day of soya bean diet the mean urine urea concentration went up to 2·84 *M*, with a maximum value of 3·41 *M*; the highest total electrolyte concentration was on the second day of salted barley diet, mean 1·098 and maximum 1·36 equiv. per litre. With carrot and barley diet or salted barley, injection of vasopressin tannate did not increase the concentration of urine, nor did aqueous posterior pituitary extract.

Cortisone prolonged the survival of animals given salted barley after removal of their adrenals. Adrenalectomised animals were able to maintain the concentration of electrolytes in the urine and to increase it in response to salted barley.—D. Duncan.

METABOLISM OF OTHER SUBSTANCES

3398

HALLIDAY, J. W. and ANDERSON, L. **The synthesis of *myo*-inositol in the rat.** *J. Biol. Chem.*, 1955, **217**, 797–802. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Radio-active *myo*-inositol (formerly *meso*-inositol) was isolated from 3 rat carcases after injections of glucose-1-^{14}C. The percentage of label incorporated was not changed when the intestinal contents were removed from the carcase of one rat and

increased slightly in the third rat when the numbers of intestinal organisms were greatly reduced by antibiotics and the intestinal contents were later removed. This showed that inositol was synthesised in the tissues. The rate of synthesis was low and the specific activity of the isolated inositol was only 3 per cent. of that of the liver glycogen.—A. Hepburn.

3399

WILSON, R. H. L., NEWMAN, E. J. and NEWMAN, H. W. **Diurnal variation in rate of alcohol metabolism.** *J. Appl. Physiol.*, 1956, **8,** 556–558. [Dept. Med., Stanford Univ. Sch. Med., San Francisco, Calif.]

Studies were made in 6 subjects of the level of alcohol in blood while they were taking whiskey in small but fixed amounts at hourly intervals for at least 36 hr. To allow rest during the night 3 doses were given as one at midnight and at 3 a.m. A representative curve for 1 subject and a curve of the means for the changes in 5 of them are reproduced and show that the level of alcohol in the blood rose between 8 p.m. and 10 a.m. and fell between 10 a.m. and 8 p.m. In the sixth subject, a nurse on night duty, the rhythm was reversed even although the study took place during her period off work when she slept during the night.

The variation in rate of metabolism appeared to depend on the pattern of activity, but its relation to meal times requires further study.—D. Harvey.

3400

OWENS, A. H. (Jr.) and MARSHALL, E. K. (Jr.) **The metabolism of ethyl alcohol in the rat.** *J. Pharmacol. Exp. Therap.*, 1955, **115,** 360–370. [Dept. Pharmacol., Johns Hopkins Univ., Baltimore, Md.]

Rats received doses of 1 or 2·5 g. ethanol per kg. bodyweight and the rate of clearance of ethanol from the blood was studied. The rate of oxidation of ethanol was constant and independent of the amount present (see Abst. 2160, Vol. 24). On a diet free from protein or after fasting the rate of oxidation decreased. Injections of sodium pyruvate, diphosphopyridine nucleotide or NaCl increased the rate of oxidation.—A. Hepburn.

MALLOV, S. and BLOCH, J. L. **Role of hypophysis and adrenals in fatty infiltration of liver resulting from acute ethanol intoxication.** *Amer. J. Physiol.*, 1956, **184,** 29–34. [Dept. Pharmacol., State Univ. New York Upstate Med. Centre, Syracuse.]

3402

LE VEEN, H. H. **Parenteral calories from a synthetic water soluble fat.** *Surg. Gynecol. Obstet.*, 1956, **102,** 154–160. [Dept. Surg., Chicago Med. Sch., Ill.]

Theoretical considerations on the structure of fatty acid derivatives and their physiological action are discussed. Aleuritic acid, a 16-C acid with —OH at the 9th, 10th and 16th atoms and a major constituent of shellac, was the starting point from which glucose monoaleuritate was prepared. It is a waxy substance miscible with water in any proportion, and has R.Q. 0·815 and energy value 6·24 Cal. per g., each value midway between those for fat and carbohydrate. In 13 per cent. solution it is isotonic with 5 per cent. glucose solution.

Experiments with rats already described [reference not given] are summarised. Given parenterally the substance is utilised to the same extent as is fat given by mouth. Neither in these animals nor in human red cells incubated *in vitro* was there evidence that it caused haemolysis, and no more than a trace of it or of the free acid could be detected in urine.—D. Harvey.

3403

SETO, T. A. and SCHULTZE, M. O. **Metabolism of trichloroethylene in the bovine.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 314–316. [Dept. Agric. Biochem., Inst. Agric., Univ. Minnesota, St. Paul.]

When 4 Holstein calves received 3 to 12 g. trichloroethylene 1 per cent. of the dose appeared in the urine as trichloroacetic acid and 13 to 25 per cent. as trichloroethanol.—T. R. Preston.

METABOLISM OF CELLS, TISSUES, ETC.

GENERAL PHYSIOLOGY

3404

FISHER, R. B. **The absorption of water and of some small solute molecules from the isolated small intestine of the rat.** *J. Physiol.*, 1955, **130,** 655–664. [Dept. Biochem., Univ. Oxford.]

For earlier publications see Absts. 4446, Vol. 19; 3077, 3177, Vol. 23; Title 4936, Vol. 24. See also Smyth and Taylor, Title 2096, Vol. 25.

Absorption of water from the surviving small intestine of the rat depends on the presence in and absorption from the lumen of glucose. The intestine being distended so that all mucosal folds were separated, *i.e.*, at a minimum pressure of 20 cm. H_2O, greater distension had little or no effect. Rate of absorption was independent of osmotic pressure and of the concentration of glucose in the lumen down to 100 mg. per 100 ml. water, the lowest used.

Urea, creatine and sorbitol were absorbed only with water and the rates of absorption were inversely as their molecular weights.—I. Leitch.

3405

WEISS, J. M. (with FLEISCH, D.) **The role of the Golgi complex in fat absorption as studied with the electron microscope with observations on the cytology of duodenal absorptive cells.** *J. Exp. Med.*, 1955, **102,** 775–782. [Dept. Anat., Sch. Med., Washington Univ., St. Louis, Mo.]

3407

SMITH, T. C. **The respiration and composition of the mammary gland of the guinea pig during pregnancy and lactation.** *Arch. Biochem. Biophys.*, 1956, **60,** 485–495. [Dept. Pharmacol., Sch. Med., Boston Univ., Mass.]

Metabolic behaviour of slices of mammary gland tissue *in vitro* was compared for guineapigs in late pregnancy and after 2, 10 and 20 days of lactation. Respiration increased to a highly significant extent after parturition, but declined between the tenth and twentieth days of lactation. Either fresh weight or defatted dry weight was a more reliable criterion of metabolic activity than dry weight.

Glucose, ketoglutarate, fumarate and citrate failed to stimulate respiration in slices from pregnant or lactating animals. Succinate was effective, and acetate caused some stimulation during pregnancy and 10 days *post partum*, but pyruvate was effective only 10 or 20 days *post partum*.

Total N and protein content of the gland increased at parturition and declined later. Deoxyribonucleic acid remained fairly constant; so did water content. Fat fell after parturition. The selection of a stable indicator of metabolic activity for the mammary gland is discussed.—D. Duncan.

3408

GLOCK, G. E., MCLEAN, P. and WHITEHEAD, J. K. **Pathways of glucose utilization in the mammary gland of the rat.** *Biochem. biophys. Acta*, 1956, **19,** 546–547. [Courtauld Inst. Biochem., Middlesex Hosp., London.]

When slices of mammary gland from rats were incubated with glucose-6-^{14}C or glucose-1-^{14}C the production of $^{14}CO_2$ from the latter was much the greater and increased to a maximum during lactation. The ratio between them was 1 : 1 at the end of pregnancy, 15·7 : 1 between the 10th and 18th days of lactation and 2 : 1 at the beginning of involution. This indicated that some oxidation of glucose occurred by a non-glycolytic route.

SCHMIDT, G. and DAVIDSON, H. M. **On the *in vitro* incorporation of ^{32}P-phosphate into phosphoproteins by lactating mammary gland.** *Biochem. biophys. Acta*, 1956, **19,** 116–120. [Res. Lab., Boston Dispensary, Mass.] French and German summaries.

A washed particulate fraction was prepared from homogenates of lactating mammary gland of rabbits by the method of Lehninger and Kennedy (Title 1998, Vol. 18). The fraction was capable of incorporating ^{32}P from phosphate into phosphoprotein; the amount incorporated was not affected by addition of bovine serum albumin, but was doubled by addition of serum from a lactating rabbit and increased eightfold by addition of casein.—D. Duncan.

SCHWARZ, V., GOLBERG, L., KOMROWER, G. M. and HOLZEL, A. **Some disturbances of erythrocyte metabolism in galactosaemia.** *Biochem. J.*, 1956, **62,** 34–40. [Dept. Pathol., Univ. Manchester.]

Human red cells from 6 normal subjects always consumed some oxygen when galactose was provided as substrate, but only 5 or 6 per cent. of the amount consumed with glucose. Red cells from a patient with galactosaemia respired in glucose, but not at all in galactose. When glucose and galactose were present together, galactose always caused a slight increase of oxygen consumption by normal red cells, but a small decrease with the patient's cells.

Chromatography of phosphate esters from red cells showed that in 2 galactosaemic patients a

change from milkless to milk-containing diet was followed within a few days by accumulation of galactose-1-phosphate in the red cells. This was not found in 6 healthy infants. Accumulation of galactose-1-phosphate also occurred in galactosaemic red cells incubated in galactose-containing media. The phosphate ester content was reduced both *in vivo* and *in vitro* and the inorganic P content fell by nearly 70 per cent.—D. Duncan.

D'Abramo, F., Ruffo, A., Tomasos, E. and Paladini, A. Alcune reazioni metaboliche dell'α-glicerofosfato. [**Metabolic reactions of α-glycerophosphate.**] *Arch. Sci. biol., Bologna*, 1955, **39,** 612–630. [Lab. Biochim., Ist. Tumori "Fond. Pascale", Naples.]

Liver homogenates were prepared from rats fasted for 24 hr. and were incubated with ^{32}P and different proportions of succinate or pyruvate, glycerol and diphosphopyridine nucleotide (DPN), and with NaF and adenosine triphosphate (ATP).

Addition of glycerol to homogenates always led to increased formation of glycogen, but less extra glycogen was formed in the presence of succinate than without it, and with succinate some pyruvic acid was formed instead. The addition of glycerol to homogenates containing pyruvate always led to formation of extra glycogen, and sometimes to accumulation of pyruvic acid. The intermediate products in the transformation of α-glycerophosphate to glycogen, identified after chromatographic separation, were phosphoglycerate, fructose-1 : 6-diphosphate, glucose-6-phosphate and glucose-1-phosphate. It is concluded that according to the experimental conditions α-glycerophosphate may be transformed either into glycogen or into pyruvic acid.—D. Duncan.

Pasieka, A. E., Morton, H. J. and Morgan, J. F. **The metabolism of animal tissues cultivated *in vitro*. 1. Amino acid metabolism of chick embryonic-heart fibroblasts cultivated in synthetic medium M 150.** *J. Nat. Cancer Inst.*, 1956, **16,** 995–1009. [Lab. Hyg., Dept. Nat. Health Welfare, Ottawa.]

The uptake of amino acids from the synthetic medium M 150 described previously (Abst. 2115, Vol. 26) by heart muscle of 11-day-old chick embryos was studied by one-dimensional paper chromatography.

Changes were slight during the first 7 days but rose to a maximum between the 14th and 25th days of cultivation. Almost all the cystine, lysine, histidine and arginine were removed from the medium, and considerable amounts of valine, phenylalanine, tryptophan, *iso*leucine and leucine. The amounts of glutamine, serine, glycine, threonine, alanine and methionine in the medium increased. Quantitative chemical studies (to be published) indicate that disappearance of amino acids was really due to uptake by the cells and not to enzymic breakdown.—W. M. Deans.

3415

Vann, L. S. **Possible function of serum proteins in tissue culture.** *Science*, 1956, **123,** 326–327. [2217 Blake St., Berkeley, Calif.]

Eagle (see Absts. 808, 2116, Vol. 26) found that dialysed serum was necessary in an otherwise chemically defined medium for growing mammalian cells. It is suggested that the essential substance or substances provided by the serum might be protein, perhaps some of the serum proteins themselves.—D. Duncan.

Eagle, H., Oyama, V. I., Levy, M., Horton, C. L. and Fleischman, R. **The growth response of mammalian cells in tissue culture to L-glutamine and L-glutamic acid.** *J. Biol. Chem.*, 1956, **218,** 607–616. [Sect. Exp. Therap., Lab. Infect. Dis., Nat. Microbiol. Inst., Nat. Insts. Health, Bethesda, Md.]

Under the experimental conditions both mouse fibroblasts and human carcinoma cells (see Absts. 808, 834, Vol. 26) required L-glutamine for survival and growth. D-Glutamine, ornithine, proline and α-ketoglutaric acid could not replace L-glutamine. The full complement of amino acids reduced the glutamine requirement. L-Glutamic acid at a much greater concentration could replace glutamine for the carcinoma cell, but not for the mouse fibroblast. NH_4Cl with glutamic acid often further increased growth of carcinoma cells and occasionally permitted slight growth of mouse fibroblasts.

Steinberg, D., and Vaughan, M. **Intracellular protein degradation *in vitro*.** *Biochim. biophys. Acta*, 1956, **19,** 584–585. [Lab. Cellular Physiol. Metabol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Liver and kidney slices from rats injected with radio-active amino acids released N.P.N. on incubation. This release was inhibited by lack of oxygen, dinitrophenol and *o*- and *p*-fluorophenylalanine. The net increment of N.P.N. during 4 hours' incubation, expressed as a percentage of total protein, was on the average $2{\cdot}7 \pm 1$. Dinitrophenol and *o*-fluorophenylalanine did not inhibit the breakdown of protein in liver homogenates. The results suggested that mammalian intracellular protein was continually being degraded and re-synthesised.—A. Hepburn.

Octanoate-1-^{14}C was incubated with liver slices from fasted rats and from rats fed on a stock diet and its conversion to CO_2, acetoacetate, glycogen, fatty acids and cholesterol was studied. The incubation was in phosphate or bicarbonate buffer or in buffer-free media of different ionic strengths with or without glucose, pyruvate or succinate.

Whatever the incubation medium, the synthesis of fatty acids and cholesterol was depressed in liver slices from fasted animals. Synthesis of long-chain fatty acids in a bicarbonate buffer by liver slices from non-fasting animals was 7 or 8 times greater than in phosphate buffer. In a high-K medium synthesis of cholesterol was enhanced by the presence of phosphate. When supplemented with pyruvate, a high-phosphate medium promoted synthesis of increased amounts of long-chain fatty acids from octanoate.—G. A. Garton.

TEPPERMAN, J., TEPPERMAN, H. M. and SCHULMAN, M. P. (with DEWITT, J. M.) **Oxidation of palmitic acid-1-C^{14} by tissues of carbohydrate and fat diet-adapted rats.** *Amer. J. Physiol.*, 1956, **184**, 80–82. [Dept. Pharmacol., State Univ. New York Upstate Med. Centre, Syracuse.]

Adult male rats were given isocaloric diets high in choline and fat or high in carbohydrate for 4 to 6 weeks. Tissue slices from liver and diaphragm were incubated with palmitic acid-1-^{14}C and the specific activity of respiratory CO_2 was estimated.

The oxidation of palmitic acid was greater in tissues from rats on the high-choline, high-fat diet and the rate of utilisation of glucose from the medium was significantly lower.

TIETZ, A. and SHAPIRO, B. **The synthesis of glycerides in liver homogenates.** *Biochem. biophys. Acta*, 1956, **19**, 374–375. [Dept. Biochem., Hebrew Univ., Hadassah Med. Sch., Jerusalem.]

Homogenates of rat liver were centrifuged to yield a fraction composed mainly of mitochondria. This preparation was incubated for 1·5 hr. at 37° C. with potassium palmitate-1-^{14}C and adenosine triphosphate (ATP) in a medium buffered at *p*H 7·5 with phosphate and containing $MgCl_2$. Glycerides were then isolated and the amount of ^{14}C present was estimated.

Palmitic acid was incorporated into glyceride combination to the same extent whether air or nitrogen was used as the gas phase; when ATP was omitted glyceride synthesis in nitrogen almost ceased and it dropped when air was the gas phase. The maximum incorporation of ^{14}C into triglycerides was 25 per cent. of that initially added.

The mitochondrial preparation was separated into sediment and supernatant fluid by high-speed centrifuge; neither fraction synthesed glyceride when tested on its own, but they did when recombined. A considerable part of the activating capacity of the supernatant fluid was retained after heating to 100° C. for 1 min. This, with the finding that NaF did not abolish synthesis of glyceride, suggests that the enzyme system responsible is probably not of the lipase type.

G. A. Garton.

3422

PERRY, W. F. and BOWEN, H. F. **Effect of adrenalectomy on the incorporation of acetate into fatty acids, cholesterol and acetoacetic acid by rat liver slices.** *Amer. J. Physiol.*, 1956, **184**, 59–62. [Dept. Physiol. Med. Res., Univ. Manitoba, Winnipeg.]

Liver slices from adrenalectomised rats fed to appetite, from pair-fed normal rats and from 2 similar groups which were also forcibly fed with glucose were incubated with acetate-2-^{14}C in phosphate and bicarbonate buffers.

Adrenalectomy reduced the amount of ^{14}C incorporated into fatty acids and cholesterol, but not into acetoacetate. Bicarbonate was the best buffer for the formation of fatty acids and phosphate buffer was best for cholesterol. Forcible feeding increased the incorporation of ^{14}C into fatty acids and cholesterol in all rats, but in the adrenalectomised rats the amount incorporated was still less than in the normal rats. Liver slices from adrenalectomised rats produced more, in the forcibly fed rats significantly more, $^{14}CO_2$ in bicarbonate buffer than liver slices from intact rats.—A. Hepburn.

3423

HAROLD, F. M., FELTS, J. M. and CHAIKOFF, I. L. **Fate of cholesterol-4-C^{14} and -26-C^{14} in the perfused liver.** *Amer. J. Physiol.*, 1955, **183**, 459–462. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Bile components were examined for radioactivity after perfusion of isolated rat liver with blood to which was added cholesterol-4-^{14}C or

cholesterol-26-^{14}C. The latter was readily oxidised to $^{14}CO_2$, though smaller amounts of ^{14}C were found in the neutral and acid fractions of the bile. By contrast, cholesterol-4-^{14}C was not oxidised to CO_2; about 10 to 20 per cent. of the ^{14}C was found in the neutral fraction of the bile and the remainder in the bile acids. By paper chromatography taurochenodeoxycholic acid, taurocholic acid and an unidentified compound were shown to be labelled. In a time study it was found that taurochenodeoxycholic acid and the unidentified metabolite became labelled with ^{14}C 1 to 2 hr. before ^{14}C was detected in taurocholic acid; the latter did not appear to be the major product of cholesterol metabolism, as it is in intact animals.

MOLNAR, G. D., ALBERT, A., KEATING, F. R. (Jr.) and ORVIS, A. L. **Iodine metabolism in surviving human and canine thyroid slices.** *Endocrinology*, 1956, **58**, 381–386. [Mayo Clin., Rochester, Minn.]

3425

FREINKEL, N. and INGBAR, S. H. **The metabolism of I^{131} by surviving slices of rat mammary tissue.** *Endocrinology*, 1956, **58**, 51–56. [Thorndike Mem. Lab., Second and Fourth Med. Serv. (Harvard), Boston City Hosp., Mass.]

Slices of mammary tissue were obtained from lactating and non-lactating rats. Thyroids, kidney and diaphragm slices from the same rats were studied under the same experimental conditions.

Both lactating and non-lactating mammary tissue collected and bound ^{131}I in organic form in the same way as thyroid, but less. Kidney and diaphragm slices did not. Lactating mammary tissue had a greater capacity for binding ^{131}I organically than mammary tissue from pregnant or non-pregnant rats. When the tissues were treated with 1-methyl-2-mercaptoimidazole they lost the power to bind I organically, but could still concentrate I as iodide. This property was depressed by thiocyanate, perchlorate or 2 : 4-dinitrophenol.—B. W. Simpson.

CARTIER, P. and PICARD, J. La minéralisation du cartilage ossifiable. [**Mineralisation of ossifiable cartilage.**] 3. Le mécanisme de la reaction ATPasique du cartilage. [**3. Mechanism of the ATP reaction of cartilage.**] 4. La signification de la réaction ATPasique. [**4. Significance of ATP reaction.**] *Bull. Soc. Chim. biol.*, 1955, **37**, 1159–1168; 1169–1176. [Lab. Étude de l'Os, Fac. Méd., Paris.]

For parts 1 and 2 see Abst. 827, Vol. 26.

3. Study of mineralisation of cartilage *in vitro* by chromatography of trichloroacetic acid extracts showed that although the Ca : P ratio was identical with that of dicalcium phosphate, this was not the form in which the minerals were deposited. Calcium pyrophosphate was identified chromatographically and by X-ray diffraction, and the depot is thought to contain about 80 per cent. pyrophosphates and 20 per cent. orthophosphates. The pyrophosphate is formed by splitting off the terminal pyrophosphate group of adenosine triphosphate (ATP). Chromatography of mineralising solutions on ion-exchange resins before and after incubation with cartilage showed that ATP is degraded to monophosphate and that the pyrophosphate group is simultaneously fixed in the cartilage; this explains the specific effect of ATP described in part 1.

4. A perchloric acid extract of cartilage from sheep embryo was shown spectrophotometrically to contain ATP. The concentration was highest in metaphyseal regions about to calcify. Bone showed stronger pyrophosphatase activity than cartilage, but less than 1 per cent. of total bone P was pyrophosphate. It is concluded that ATP takes part in the initial stages of mineralisation in the presence of orthophosphates. Ossifiable cartilage can form ATP in the presence of orthophosphates and 5-adenylic acid.—D. Duncan.

GROWTH AND METABOLISM OF TUMOUR CELLS

3427

ENGELBRETH-HOLM, J. and IVERSEN, S. **Is vegetable Annatto butter colour cancrogenic?** *Acta pathol. microbiol. scand.*, 1955, **37**, 483–491. [Fibiger Lab., Pathol. Anat. Inst., Univ. Copenhagen.]

One hundred female rats of a uniform but not inbred strain, weighing at the outset about 75 g., were given daily by dropper 26 mg. Annatto (the Danish vegetable colour bixin; see Title 285, Vol. 24) in soya oil for 26 months. They did not differ significantly in bodyweight or in number and kind of tumours present at natural death from a control group of 100 untreated female rats.

A group of 50 male and 50 female mice, littermates of the inbred ST/EL strain, daily had 1 drop of 10 per cent. Annatto in soya oil by dropper from 6 weeks of age until death. Again there was no significant difference between them and an untreated group in bodyweight or tumour incidence; in particular, there was no liver degeneration, cirrhosis or liver tumour in the treated mice. Injection of Annatto into mice or painting their skin with it was likewise not effective. There was a hint that pulmonary tumours were slightly more frequent in treated females and liver tumours slightly less frequent in treated male mice.

JARDETZKY, O., VISSCHER, M. B. and KING, J. T. **Development of spontaneous hepatoma in mice in relation to composition of dietary fat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 648–650. [Dept. Physiol., Med. Sch., Univ. Minnesota, Minneapolis.]

A hydrogenated vegetable fat, Crisco, was separated into 5 fractions by crystallisation from ether at low temperatures; the fractions differed in melting-point, mean molecular weight of component fatty acids and degree of unsaturation. Lard, unfractionated Crisco or these fractions were incorporated as 17·5 per cent. of a diet which also contained casein 29, glucose 34, yeast 8·2, salt mixture 4·1, alfalfa leaf 4·1, cod liver oil 2·1 and wheat germ oil 1·0 per cent.; these diets were given to appetite to groups of weanling mice for 54 weeks.

At autopsy a high proportion of hepatomas was found in mice which had been given the fat fractions of low melting-point, containing mostly unsaturated and shorter-chain fatty acids; fractions of high melting-point gave rise to few hepatomas. It remains to be established whether the differences are due to the composition or the amounts of fat absorbed.—G. A. Garton.

3429

BENSON, J., LEV, M. and GRAND, C. G. **Enhancement of mammary fibroadenomas in the female rat by a high fat diet.** *Cancer Res.*, 1956, **16,** 135–137. [Res. Labs., Mount Sinai Hosp., Miami Beach, Fla.]

Fibroadenomas developed in the mammary glands of 34 out of 81 female rats over 18 months old after they had been fed for 10 months on a stock diet to which 20 per cent. olive oil had been added; similar tumours developed in only 3 out of 12 animals on the stock diet supplemented with lettuce and carrot. No tumour developed in younger rats. Serum lipid values were higher in fat-fed rats, and this may be related to the genesis of such tumours. A variety of treatments failed to prevent the tumours.—G.A.Garton.

3430

MULAY, A. S. and EYESTONE, W. H. **Transplantable adrenocortical adenocarcinomas in Osborne-Mendel rats fed a carcinogenic diet.** *J. Nat. Cancer Inst.*, 1955, **16,** 723–729. [Nat. Cancer Inst., Nat. Insts. Health, Pub. Health Serv., Bethesda, Md.]

Two groups of 30 female rats were given semi-synthetic diets containing either 6 or 8 per cent. casein and 0·06 per cent. *p*-dimethylaminoazobenzene for 286 days; they were then given a diet of Purina chow pellets. Of 42 rats which survived to the age of 18 months or more, 27 developed adrenocortical adenoma and 4 adrenocortical adenocarcinoma. The adenocarcinoma was accompanied by metastases in lung and liver. The adrenal tumours were successfully transplanted to male and female rats and grew to an average weight of 15 to 20 g. in 3 to 4 months; there were metastases in liver and lungs of the host.—G. F. Garton.

3431

MARCHANT, J. **Influence of pregnancy and lactation on the incidence of mammary carcinoma induced with methylcholanthrene in female mice of the "*IF*" strain.** *J. Pathol. Bacteriol.*, 1955, **70,** 415–418. [Cancer Res. Labs., Med. Sch., Birmingham.]

Twelve out of 16 virgin mice of the *IF* strain, which has a very low incidence of spontaneous mammary tumours, developed mammary tumours after application of methylcholanthrene. No tumour appeared in 11 mice of this strain which were suckling their first litter when treatment with methylcholanthrene was begun, and only 2 tumours in 7 mice in which treatment began at mating.

It is concluded that lactation protects mice of this strain against this type of mammary tumour.
D. Duncan.

CAMPBELL, P. N., JONES, H. E. H. and STONE, N. E. **Plasma protein as a precursor of rat liver and hepatoma protein.** *Nature*, 1956, **177,** 138–139. [Courtauld Inst. Biochem., Middlesex Hosp. Med. Sch., London, W.1.]

One rat was given an intraperitoneal injection of 50μC. of L-^{14}C-lysine and was killed after 6 hr.; the plasma was fractionated to give a purified preparation of radio-active albumin. A second rat which had several hepatomas produced by dietary 4-dimethylaminoazobenzene was injected intravenously with 150 mg. of the ^{14}C-lysine-albumin in 3 ml. of saline, with 20μC. of L^{14}C-alanine; after 95 min. the rat was killed and the hepatoma tissue and liver tissue were separated and amino acids were estimated by ion-exchange chromatography. The specific radio-activity of the lysine and alanine from each protein fraction was estimated.

The ratio of the specific radio-activity of alanine to that of lysine from the hepatoma protein was 9·8 and from the liver 10·3. These results suggest that amino acids derived from serum albumin are not incorporated into the soluble proteins of hepatoma tissue to a greater extent than into those of liver tissue. Estimation of the amounts of albumin in extracts from the 2 tissues by precipitation with an anti-serum for serum albumin showed that 8·4 per cent. of the soluble protein from hepatoma and 4 per cent. of that from the liver consisted of serum albumin.—G. F. Garton.

3433

INGLE, D. J., FLORES, V. and TORRALBA, G. **Effect of tumors on level of plasma amino acids of eviscerate rats.** *Proc. Soc. Exp. Biol. Med.*, 1956, **91,** 168–169. [Ben May Lab. Cancer Res., Univ. Chicago, Ill.]

The increase of plasma amino acids in rats after evisceration was much more rapid when tumours were present and was positively related to the weight of the tumour. Glucose infused with or without insulin did not prevent the increase in rats with tumours.—A. Hepburn.

3434

KIT, S. **The biosynthesis of free glycine and serine by tumours.** *Cancer Res.*, 1955, **15,** 715–718. [Dept. Biochem., Univ. Texas M.D. Anderson Hosp., Houston.]

Experiments in which Gardner tumour cells were incubated with radio-active glucose, acetate, ribose and formate suggest that glycine was formed from serine and that serine was formed from phosphoglycerate but not from pyruvate. Acetate apparently traversed the citric acid cycle. A hypothetical pathway is proposed.—A. Hepburn.

3435

DUNN, M. S. and MURPHY, E. A. **Effect of ethionine alone or with amino acids on tumor growth, carcass weight, and nonprotein amino acids in rat liver.** *Cancer Res.*, 1955, **15,** 760–672. [Chem. Lab., Univ. California, Los Angeles.]

Rats on a stock diet were inoculated subcutaneously with Sarcoma R-1 and 7 days later they were weighed and the area of tumours was measured. On the tenth day they were divided among 5 groups each of 15 animals and were given intraperitoneal injections daily of ethionine alone or with 50 mg. L-arginine, 125 mg. glycine or 50 mg. L-lysine; a control group had injections of physiological salt solution. Some were killed after one injection, the remainder after 7. The free and bound forms of non-protein amino acids were estimated in livers.

In the rats given 7 injections gains of bodyweight and growth in size of tumours were less in the ethionine groups than in the control group; the addition of an amino acid did not affect the change produced by ethionine. The 8 amino acids studied in liver were arginine, aspartic acid, glutamic acid, glycine, lysine, methionine, proline and serine. The amounts of both forms of all acids, except arginine, were greater in the ethionine groups than in the control group. For 5 acids the increase in total was greater than in the bound form; the exceptions were methionine, of which both forms increased to the same extent, and serine, for which the increase was greater in free than in total.

In the rats killed after one injection similar but less extensive changes were found.—D. Harvey.

3436

MEDES, G., FRIEDMANN, B. and WEINHOUSE, S. **Fatty acid metabolism. 8. Acetate metabolism *in vitro* during hepatocarcinogenesis by *p*-dimethylaminoazobenzene.** *Cancer Res.*, 1956, **16,** 57–62. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Acetate-2-^{14}C was incubated for 4 hr. at 37·6° C. in oxygen with liver slices from normal rats, with "pre-neoplastic" liver slices from rats which had been fed for several months on a diet containing 0·06 per cent. *p*-dimethylaminoazobenzene, and with liver tumour tissue from rats which had received the carcinogen for longer periods. Respired CO_2 was collected and tested for ^{14}C and the extent of incorporation of ^{14}C into acetoacetate, fatty acids and cholesterol was estimated.

Conversion of ^{14}C-acetate to CO_2 and cholesterol was similar in all the tissues studied, but much less acetoacetate and fatty acid were formed in primary tumour tissues than in normal or pre-neoplastic liver. It appears, therefore, that disturbance of acetate metabolism occurs abruptly with the development of tumour tissue.

G. A. Garton.

3437

DAS GUPTA, N. N., BHATTACHARYA, K. L., DUTT CHOUDHURI, R., BOSE, A. and DE, P. K. **The uptake of radioactive phosphorus in normal breast and breast tumors.** *Acta radiol.*, 1956, **45,** 69–80. [Chittaranjan Cancer Hosp., Calcutta.] German and French summaries.

Of 48 breast tumours studied, 20 were histologically malignant. The patients each received a single dose of ^{32}P by vein, about 0·01 μC. per g. bodyweight. The β-activity was measured by Geiger counter on the skin over the normal breast and over the tumour 2, 6, 10, 24, 30, 36 and 48 hr. later. The mean ratio of radio-activity between tumour and normal breast was thought to be more significant than the ratio at any one time. Some tumours were subsequently removed and samples of malignant and non-malignant areas were ashed for study of radio-activity.

Of the 20 malignant tumours 17 had mean radio-activity 130 per cent. or more of that of the normal breast and 3 had less than 130 per cent. Of the 28 benign tumours, 23 had counts of less than 130 per cent. If a count of more than 130 per cent. was taken as suggestive of malignancy, the diagnosis was confirmed by the histological findings in 40 out of 48 cases.

Because of large statistical error, no appreciable difference in the rate of accumulation or release of ^{32}P between tumour and normal tissue could be established with certainty. In 10 samples of

malignant tissue the activity was from 124 to 1040 per cent. of that in the normal samples, mean 500 per cent.

The value of this method as a diagnostic procedure is discussed.—D. Duncan.

3438

ALLISON, J. B., WANNEMACHER, R. W. (Jr.), HILF, R. and CROSSLEY, M. L. **Diet and TEPA therapy in sarcoma-bearing rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 728–730. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

Earlier work is summarised (Title 4783, Vol. 24; Abst. 3946, Title 5406, Vol. 25). With the same techniques as before and a diet with 12 per cent. casein, the following supplements were tested for their possible effect on the actions of N, N′, N″ triethylene phosphoramide (TEPA): DL-methionine or DL-methionine with guanidoacetic acid, each 0·67 per cent.; glycine 1·28, alanine 1·53, ammonium citrate 1·95 and casein 1·5 per cent., each of these supplying N equivalent to that in 0·67 per cent. guanidoacetic acid.

In 3 weeks the tumour had reached lethal proportions, 36·7 g., in rats not given TEPA. As before, TEPA reduced tumour growth and also body growth and efficiency of use of food. Supplements of methionine or methionine with guanidoacetic acid improved use of food and growth of the body, a change associated with reduced excretion of urea, without increasing growth of the tumour.

FERGUSON, A. D., CUTTER, F. F. and SCOTT, R. B. **Growth and development of Negro infants. 6. Relationship of certain environmental factors to neuromuscular development during the first year of life.** *J. Pediat.*, 1956, **48,** 308–313. [Dept. Paediat., Coll. Med., Howard Univ., Washington, D.C.]

For part 5 see Title 845, Vol. 26.

6. In negro infants bodyweight and age of walking alone were inversely correlated. Age of walking alone was not significantly related to measured intelligence, number of siblings, or educational status of mother.—F. C. Aitken.

3442

LELONG, M. La méthode anthropométrique en auxo-endocrinologie. [**The anthropometric approach in the endocrinology of growth.**] *Ann. paediat.*, 1956, **186,** 149–162. [Clin. Puéricult., Hôp. Saint-Vincent-de-Paul, Paris.] German and English summaries.

After a discussion of the advantages and disadvantages of the methods of Wetzel, De Toni and others for graphical representation of the growth of children, a device is described [but not illustrated] which, by the adjustment of 2 threads, gives the normal height, weight and other body measurements for a boy or girl of given age, or weight and other body measurements for a boy or girl of given height. Norms are from Wilkins's modification of Engelbach's tables. Nomograms devised by Scholler for boys and girls give the percentage deviations from normal. When these are plotted at different ages, the curve of development of an individual child is obtained, by means of which he can be compared with himself as well as with the average child of the same age (see also Abst. 961, Vol. 25).—W. M. Deans.

3443

BAYLEY, N. **Growth curves of height and weight by age for boys and girls, scaled according to physical maturity.** *J. Pediat.*, 1956, **48,** 187–194. [Nat. Inst. Mental Health, Nat. Insts. Health, Bethesda, Md.]

Growth curves of height and weight for age for boys and girls maturing at average, accelerated and retarded rates are presented as standards for the assessment of individual growth curves. Annual increment curves for the average child maturing at the average rate are given also.

Comparison of a child's increment curve with the standard increment curve will show with which standard growth curve his or her own growth curve should be compared.

The basic data used in the standard curves were obtained from repeated measurements from birth to 18 or 21 years of 300 healthy Californian children. These data are tabulated. Physical maturity was estimated from X-ray studies of hand and knee and from the percentage attained of each child's adult stature.—F. C. Aitken.

3444

MARKOWITZ, S. D. **Retardation in growth of children in Europe and Asia during World War II.** *Human Biol.*, 1955, **27**, 258–273. [Madison, Wis.]

The data available for comparison of war-time with pre-war rates of growth of children in Belgium, China, England, Finland, France, Germany, Greece, Holland, Italy and Japan and for birthweights of infants in Germany, Holland, Russia and Switzerland are assembled. Retardation of growth as a result of war-time conditions was demonstrable in all the populations, but its contributory causes were not separable as nutritional or psychological in origin, since mental strain was generally greatest where food was scarcest.—D. Harvey.

3445

SCOTT, J. A. **Report on the heights and weights of school pupils in the County of London in 1954.** London County Council, 1955, pp. 28.

Schools were chosen at random within the 9 health divisions of the County of London so as to obtain a sample geographically and socially representative. In all, 10,904 boys and 10,099 girls were weighed and measured.

As in earlier years, boys were on the average taller and heavier than girls up to the age of 11 years; the positions were reversed from 11 to 14 and thereafter boys resumed their superiority, first for height and later for weight. Differences between children in different parts of the County found in earlier years have almost disappeared. Between 1949 and 1954 the average height and weight of boys increased by about 1·5 cm. (0·59 in.) and about 1·5 kg. (3·3 lb.). The average gains for girls were 1 cm. (0·39 in.) and 1 kg. (2·2 lb.). It is pointed out that these results do not preclude the attainment of the same adult stature at an earlier age rather than a general increase in stature of succeeding generations; also that the general increase in measurements at an interval of time may mask an intervening peak and the beginning of a fall. The ratios of weight : height were slightly greater in 1954 than in 1949 and are summarised as having remained substantially unaltered.

The age of onset of puberty, estimated approximately by asking boys if breaking of the voice had occurred and girls if menstruation had begun, was between 9·9 and 16·6 years in boys and between 10·3 and 15·8 years in girls.—F. C. Aitken.

3446

KEDDIE, J. A. G. **Heights and weights of Scottish schoolchildren.** *Brit. J. Prev. Social Med.*, 1956, **10**, 1–14. [Dept. Health for Scotland, Edinburgh.]

Children attending Scottish education authority schools have a systematic medical examination at 5, 9, 13 and 16 years of age. The data considered in this report were obtained at these examinations. For Edinburgh and Glasgow children aged 5, 9 and 13 years, measurements were available for the years 1913–14 to 1953–54. The average heights and weights in 1953–54 were significantly greater than in 1913–14. A few averages had increased significantly by 1931–32, but the chief increases occurred in steady annual increments in the next 20 years. The average heights and weights of the Edinburgh children were greater than those of Glasgow children in 1913–14. The differences were less in 1953–54, but many were still statistically significant. Average gains in Edinburgh were: at 5 years, boys 1·29 in., 2·07 lb., girls 1·04 in., 1·31 lb.; at 9 years, boys 2·92 in., 7·45 lb., girls 2·30 in., 7·19 lb.; at 13 years, boys 3·57 in., 14·37 lb., girls 0·85 in., 12·68 lb. Average gains in Glasgow were: at 5 years, boys 1·93 in., 4·35 lb., girls 1·64 in., 3·69 lb.; at 9 years, boys 4·00 in., 8·36 lb., girls 2·53 in., 6·98 lb.; at 13 years, boys 3·91 in., 14·53 lb., girls 3·18 in., 16·41 lb. The ratios of average weight to average height of Glasgow children were calculated for the years 1938 to 1954. The ratios are said to have varied only slightly throughout the period.

The changes in mean heights and weights of children aged 5, 9, 13 and 16 years in the 6 years 1948–49 to 1953–54 were studied from combined data of Edinburgh, Glasgow, Dundee and Ayrshire, representing the school population of the central industrial belt. Statistical analysis of the differences between 1953–54 and 1952–53 and between 1953–54 and 1948–49 confirmed the upward trend in average heights and weights of children of school age. For all the ages, heights and weights were significantly higher in 1953–54 than in 1948–49. In the comparison of 1953–54 with 1952–53 the differences in favour of 1953–54 which were not significant were height of 16-year-old boys, and of 9- and 16-year-old girls.

All-Scotland average heights and weights were computed for 1951–52 and 1952–53. Adjusted to the uniform ages $5\frac{4}{12}$, $9\frac{6}{12}$, $13\frac{6}{12}$, these were in 1952–53: boys, 43·00 in. and 43·12 lb. at 5 years, 51·93 in. and 64·27 lb. at 9 years, 59·52 in. and

93·52 lb. at 13 years; girls, 42·61 in. and 41·50 lb. at 5 years, 51·54 in. and 62·04 lb. at 9 years, 59·99 in. and 97·53 lb. at 13 years. These averages, compared with the 1951–52 averages, tended to confirm the upward trend in heights and weights of boys and girls in Scotland.

Regional analysis of the data for children aged 5, 9 and 13 in 1951–52 and 1952–53 showed that, almost invariably, the Highlands and Southern Counties had the highest and second highest average heights and weights, Glasgow the lowest, the region Edinburgh, Aberdeen and Dundee the second lowest, with the Eastern Counties and the Western-Central industrial region occupying intermediate positions. The average measurements of children in predominantly rural areas were above, and those of children in predominantly industrial regions below, the corresponding all-Scotland averages. A further study of children aged 5, 9, 13 and 16 in 4 highly industrial large burghs, and 4 less industrial large burghs, showed higher average heights and weights in the latter. Regional data for 16-year-old secondary school children are tabulated separately, since these are not considered representative of the children of that age in the community. The all-Scotland averages for 1952–53 were: boys, 67·70 in. and 134·91 lb.; girls, 63·66 in. and 123·57 lb. Averages were not significantly different from those of 1951–52.

[The all-Scotland mean height of boys aged 13 in 1951–52 is given in Table VII of the text as 59·97 in. and in Table C of the appendix as 59·57. Table IV of the text should read ratio of average weight (kg.) to average height (cm.) and not vice versa.]—F. C. Aitken.

PROSPERI, P. Valori auxometrici del bambino toscano. [**Measurements of Tuscan children.**] Studio statistico sulle alterazioni dell'accrescimento del bambino toxano. [**Statistical study of the variations in growth of Tuscan children.**] *Riv. Clin. pediat.*, 1955, **56,** 26–48; 150–169. [Clin. Pediat., Univ. Florence.] English and French summaries.

(a) Measurements of height and weight were made in the years 1949–54 on 2954 boys and 2288 girls distributed over each month of age for the first 12, and over each year for the first 14. The children were those who came from the different parts of Tuscany to the out-patient clinic of the Ente Nazionale per l'Assistenza Statali; they were considered representative of the children of Tuscany. The mean values are tabulated and compared with those obtained by other workers and for other parts of Italy. They show that in weight and height the children of Tuscany are superior to all other Italian children at all ages examined, and that the children of Florence are similarly superior to the children of other Italian cities and to the children of Florence 30 years ago.

(b) The values obtained for 2747 of the children, those from 3 to 12 years old, were further analysed for the extent of their variation. The system chosen for assessing normality is that of G. de Toni [6 references are given, with no indication of which is the key reference]. On that basis the percentage of children whose growth was accepted as within the normal range was 65·425. A larger proportion of children showed growth within the normal range at 3 years old than at any other age. The largest proportion of abnormality was at 11 years old. The growth of more children was above the normal range than below it. Of those exceedingly abnormal, the largest proportion was obese, with a certain proportion of giants and a still smaller proportion of dwarfs. The general picture for Tuscan children was considered more favourable than for Ligurian or Neapolitan children or for Italian children in general.—E. M. Hume.

3448

WADDY, B. B. **Heights and weights of children in the Northern Territories of the Gold Coast.** *J. Trop. Med. Hyg.*, 1956, **59,** 1–4. [Ross Inst., London Sch. Hyg. Trop. Med.]

Children between the ages of 6 and 12 years were weighed and measured. They belonged to the eastern half of the Northern Territories and, in spite of the absence of dates of birth, their ages as calculated from their years of attendance at school were thought to be approximately right. The means at yearly intervals are tabulated for 2648 boys and 883 girls. Tables are given also for 1666 boys and 497 girls in one area where the staple food is grain and bilharziasis is common, and for 859 boys and 354 girls in another where yams are the staple food and the disease is absent. Between the areas there was no difference in heights or weights of boys or in heights of girls; weights of girls were greater in the second than in the first.

From comparison with the few data available for African and with those quoted by Clements (Abst. 4975, Vol. 24) for English children the view is advanced that inadequacy of nutrition prevents the former from attaining in general the degree of physical development of the latter.—D. Harvey.

3449

SAITO, K. and FUNAKAWA, H. **Recent status of physical growth of Japanese children from birth to 6 years and comparison with observations made ten years previously.** *Bull. Inst. Pub. Health, Tokyo,* 1954–55, **4,** No. 3, English part, 13–17. [Dept. Maternal Child Health, Tokyo.]

In 1940, measurements were made on 24,708 infants and pre-school children (Abst. 873, Vol. 20). In 1950 height, weight, chest girth and head girth were measured for 14,009 boys and 13,309 girls, including infants for every month of age from birth to 12, and pre-school children for every year from 1 to 6. They were selected to be representative of different parts of the country. The mean values are tabulated. At birth the mean height was slightly less and the mean weight slightly more in 1950 than in 1940. The physical growth in 1950 was in general superior to that in 1940, with the exception of height at pre-school age.

BANDY, P. J., COWAN, I. M., KITTS, W. D. and WOOD, A. J. **A method for the assessment of the nutritional status of wild ungulates.** *Canad. J. Zool.*, 1956, **34,** 48–52. [Dept. Zool., Univ. British Columbia, Vancouver.]

Groups of Columbian black-tailed deer, *Odocoileus hemionus columbianus*, were reared from birth on high and low planes of nutrition which will be described elsewhere. Ten animals on each plane were measured weekly. Growing animals over 2 years showed a linear relation between bodyweight and chest girth behind the axilla, called heart girth. There was another linear relation between bodyweight and length of the hind foot from the tip of the hoof to the tip of the calcaneus when the animal was standing. The first relation varies with the condition of the animal, the second is a skeletal ratio and depends only slightly on condition. The condition of the animal is then expressed by comparing the ideal weight as estimated from the length of the foot with the actual weight as estimated from heart girth. Of 2 deer with identical heart girths, one on each plane of nutrition, the animal on low plane was older and had greater skeletal growth and so its index of condition was 0·96, against 1·18 for the animal on high plane. Similarly, of 2 deer with the same hind foot length the high-plane animal was twice as heavy as the low-plane one, and the indices were 1·84 and 0·95, respectively.

LOWRANCE, E. W. **Roentgenographic record of growth of the femur of the rabbit.** *Growth*, 1955, **19,** 247–255. [Dept. Anat., Univ. Missouri, Columbia.]

X-ray photographs were taken of the femurs of a large number of rabbits of ages from 15 to 204 days, and measurements were made on them of length and diameter.

The mean length increased from 32 to 88 mm. and the mean diameter from 3·2 to 7·3 mm. Ninety-seven per cent. of adult length and diameter (measurements at 204 days) were reached at about 130 days after birth. There was no significant difference between sexes in length or diameter of the femur.—R. Hill.

SCOTLAND, W. H. D. **Length of gestation of East African women.** *J. Obstet. Gynaecol. Brit. Empire*, 1956, **63,** 120–123. [Dept. Obstet., Med. Sch., Makerere Coll., Kampala, Uganda.]

Mean birthweights for 2500 infants in Uganda, 60 per cent. Bantu, 20 per cent. Nilotic and the remainder mainly Hamitic in origin, were for the Bantu 6·44 and for the non-Bantu 6·38 lb. These are lower than the weights quoted for white and Bantu infants in South Africa (Abst. 3878, Vol. 21), for white infants in Britain (Abst. 2602, Vol. 22) and for white and negro infants in the United States (Taback, *J. Amer. Med. Assoc.*, 1951, **146,** 901). Head measurements were made within 12 hr. of birth and again on the fourth day in 402 infants born spontaneously and unselected except for the exclusion of any with excessively moulded heads. In 97 per cent. of them occipito-frontal circumference increased in that time by about 0·25 in. Information was obtained, with stringent precautions, from 366 mothers. The average length of gestation was 42 weeks ; it was 40 weeks or more in 80 per cent. of them.

The possible relation of disordered metabolism of oestrogens to these findings is discussed.

D. Harvey.

BROWN, T. **Electrophoretic analysis of serum proteins in pregnancy. 2. Effect of labour and lactation.** *J. Obstet. Gynaecol. Brit. Empire*, 1956, **63,** 100–106. [Dept. Res., Royal Maternity Hosp., Glasgow.]

For part 1 see Abst. 3968, Vol. 25.

2. In 10 healthy pregnant women, the mean value of 6·427 g. total protein per 100 ml. serum within 12 hr. before labour was similar to the average for the last trimester of pregnancy, but the constituents had altered. Albumin continued to fall to a level of 2·61 g. per 100 ml. and the globulin, particularly the γ-fraction, rose, so that the albumin : globulin ratio was 0·69.

In the same women, within 24 hr. after labour, the mean level of albumin had fallen still further to 2·53 g. per 100 ml. and the globulin, particularly the γ-fraction, had risen ; the albumin : globulin ratio was 0·615 and total protein 6·645 g. per 100 ml. There was considerable individual variation and even the direction of the changes was not invariable.

On the fifth day *post partum* in 10 women with established lactation, average total protein was 6·62 g. per 100 ml. ; the mean level of albumin rose to 2·79 and mean total globulin fell from 4·12 after delivery to 3·828 g. per 100 ml. The fall in globulin was due to the β- and γ-fractions.

THOMSEN, K. Über die Aktivität der alkalischen Phosphatase in der menschlichen Placenta. [**Activity of alkaline phosphatase in the human placenta.**] Histochemische Untersuchungen über die saure Phosphatase in der menschlichen Placenta. [**Histochemical studies of acid phosphatase in the human placenta.**] *Arch. Gynäkol.*, 1955–56, **187,** 1–19 ; 264–281. [Frauenklin., Univ. Hamburg, Eppendorf.]

(a) One hundred human placentae, of which 65 were normal ones obtained at different stages of pregnancy and 35 were obtained after abortion, intra-uterine death or toxaemia of late pregnancy, were examined for alkaline phosphatase by Gomori's method as modified by Goetsch *et al.* (*Proc. Soc. Exp. Biol. Med.*, 1952, **80,** 71).

In normal placentae alkaline phosphatase was found especially in the protoplasm of the syncytium. Activity was erratic in distribution up to the tenth week ; thereafter it became more uniform and gradually increased up to the 30th week ; in late pregnancy it declined. Increasing activity was found in maternal intervillous blood, but none was found in the blood of the foetus. The suggestion is made that alkaline phosphatase may have something to do with transfer of glycogen and fats to the foetal blood.

(b) In the same material, acid phosphatase activity was found to behave in almost the opposite way. In the syncytium activity was greatest about the third month and then fell steadily. Acid phosphatase was not found in maternal or foetal blood. It is thought to be concerned in the preparation of nutrients for the young foetus rather than in their transfer. In pathological material it was associated with regions of calcification.—W. M. Deans.

3459

MISCHEL, W. Die biogenen Amine der Placenta. 2. Der Kreatin- und Kreatiningehalt der menschlichen Placenta. [**The biogenic amines of the placenta. 2. Creatine and creatinine content of the human placenta.**] *Arch. Gynäkol.*, 1954 – 55, **185,** 713 – 725. [Frauenklin., Univ. Leipzig.]

Part 1 appeared in *Ztschr. Geburtshilfe*, 1954, **141,** 334.

Literature on the occurrence of choline, acetylcholine, arginine, histidine, lysine, tryptophan and histamine in the placenta is briefly reviewed.

In 68 immature and mature placentae (50 normal), creatine was estimated by conversion into creatinine by the method of Jipp and Menne (Abst. 1342, Vol. 20) and adsorption on fuller's earth (Abst. 2808, Vol. 7) ; the creatinine was eluted with picrate and estimated colorimetrically by the Jaffé reaction. Creatinine originally present was also estimated by the Jaffé reaction and creatine was found by difference.

The normal values found per 100 g. fresh tissue were : creatine 11·31, range 4·00 to 19·60, creatinine 5·5, range 3·50 to 9·00 mg. The much higher values in blood reported in the literature, *e.g.*, by Kessler and Albers (Title, p. 114, Vol. 4) are considered doubtful and should be re-investigated. Values in the placenta were unaffected by

sex of child and parity of mother; on the effect of prematurity there was insufficient evidence. In placentae from patients with toxicosis creatine was the same, creatinine about 15 per cent. higher.
W. M. Deans.

JAFFÉ, W. G. Nota preliminar sobre la influencia de factores dietéticos en la fertilidad de ratones y ratas. [**Preliminary note on the effect of dietary components on fertility in mice and rats.**] *Arch. venezol. Nutricion*, 1955, **6**, 49–59. [Inst. Nac. Nutrición.] English and German summaries.

It was earlier shown that addition of vitamin B_{12} to a diet of maize and extracted soya bean meal with minerals and vitamins made it equal, for reproduction, to a commercial food with fishmeal and dried skimmed milk (Abst. 4962, Vol. 25). In the present series rats and mice were bred on diets of maize flour 46, extracted soya bean meal 46, sesame oil 5 and salts 2 with vitamins A, D, E and B complex. One group had 5 μg. vitamin B_{12} per kg. diet, one had 30 μg. vitamin B_{12} per kg. and 0·2 per cent. methionine, and another had 7·5 per cent. of the above diet replaced by fishmeal. The normal diet for comparison was a commercial rat diet. The numbers of experimental litters on each diet varied from 14 to 37 and of controls were 70 (rats) and 50 (mice). In both rats and mice control litters and litters from mice given fishmeal were larger, 9·5 and 8·3 against 7·4 and 7·5, and heavier, 6·1 and 1·4 and 1·43 g. as against 5·5 and 1·4 and 1·37 g. Litters were reduced to 6 and there was no difference between numbers reared.

In a later series, replacement of extracted by whole soya bean meal and reduction of sesame oil to 1 per cent. gave results even better than those of groups with fishmeal.—I. Leitch.

CAHN, T. and HOUGET, J. Le transport des métabolites au cours de la gestation de la lapine. [**Transport of metabolites during pregnancy in the rabbit.**] *J. Physiol., Paris*, 1955, **47**, 835–848. [Lab. Physiol., Inst. Biol. Phys. Chim., Paris.]

Rabbits were killed on the 19th, 21st, 24th and 29th days of gestation. Blood and liver were obtained and the "foetal and maternal parts of the placenta" [*i.e.*, placenta and decidua] were separated.

Analyses of blood cells and plasma and of liver from non-pregnant rabbits gave a basis for comparison. The variations found during pregnancy are expressed as percentages of these basal values. From the 19th to the 29th day the plasma showed a slight fall in protein concentration to about 10 per cent. below normal; glycerides rose from 3 times normal to 5 times at the 21st day and then fell sharply to half normal on the 29th day. Fatty acids, lipoid P and free cholesterol all rose between the 19th and the 21st day and then fell very low before parturition. Ester cholesterol fell continuously to about a tenth of normal. The proportion of red cells in the blood was about 10 per cent. below normal throughout the second half of pregnancy. Their fatty acid content was 40 per cent. above normal on the 19th day, twice normal by the 24th day and almost back to normal by the end of pregnancy. Variations in the proteins, lipoid P and free cholesterol were slight.

On the 19th day the liver was enlarged by 35 per cent. above its normal size and after the 21st day it slowly regressed. The water content followed the same pattern. Liver glycogen was about twice normal on the 19th day and 2½ times on the 21st, then fell slowly to about twice normal before parturition. Total glycerides were extremely high, especially on the 24th day. Protein, cholesterol and lipoid P all fell during the period of study, but only P was below normal at the end.

The decidua reached its greatest weight, about 3 g., on the 21st day and remained at this weight until parturition. It had a high glycogen content, falling from 7·44 per cent. on the 19th day to 3·25 per cent. on the 29th. The water content rose from 79·8 to 83·2 per cent. and the amount of water per g. protein was nearly double that in the liver. The fatty acid content was about 1 per cent., but there was a fall in lipoid P and a large increase in glycerides, which rose from 22 to 67 per cent. of the total fatty acid. The placenta grew steadily from a mean weight of 0·73 g. on the 19th day to 2·93 on the 29th. The water content was steady at about 84 per cent. The glycogen content was very small and almost nil at the end of gestation, but the fatty acid content was twice that of the decidua; the glyceride content was already high on the 19th day and did not increase as much as that of the decidua. The content of cholesterol esters was as much as 20 times that in the decidua and often 5 times that in the liver. Free cholesterol was in much the same concentration in placenta, decidua and liver. The high concentration of glycogen in liver cannot be attributed to progesterone or the other sex hormones normally associated with gestation, and with the changes in transport of lipids they suggest participation of some other hormone, probably from the pituitary or adrenal. It seems likely that the placenta synthesises phospholipins. The ester cholesterol may serve to transport fatty acids from the placenta to the foetus. The glycerides of the embryo are mostly formed from fatty acids received in this way.—D. Duncan.

BOURDEL, G. and JACQUOT, R. Rôle du placenta dans les facultés anabolisantes des rattes gestantes. [**Role of the placenta in the anabolising power of the pregnant rat.**] *C.R. Acad. Sci.*, 1956, **242**, 552–555.

For earlier work see Absts. 924, Vol. 24; 977, Vol. 25.

Female rats on a balanced diet were mated. On the 13th day of pregnancy they were divided into 4 groups and submitted to operative procedures as follows: in 1 group removal of several foetuses, but not all; in a second group removal of all foetuses, the placentae being left; in the third group removal of all foetuses and castration; and in the fourth, removal of the whole product of gestation. The N balance was studied from 16 days before mating until the rats were killed on the 21st day after mating.

Before mating the rats gained a little weight, 4 to 7 per cent. of the initial weight in 16 days. In the first 13 days of pregnancy the gain of weight was from 12 to 17 per cent., an illustration of the early stage at which bodyweight is increased. After operation the loss of weight depended on the character of the procedure and varied from 1·3 per cent. in group 1 to 3·5 per cent. in group 3. The first 3 groups then resumed their gains, so that their total gain by the 21st day was 23·5, 15·7 and 15·4 per cent. The rats in which pregnancy had been terminated had lost 6 per cent. of their weight between the 13th and 21st days.

The N balances were slightly positive before mating. During pregnancy N retention increased until operation in all groups and then fell for 48 hr. After this time there was again increased retention and the first 3 groups retained, respectively, averages of 568, 528 and 463 mg. N after operation. The mean retention in 6 days before mating was 312 mg. Thus neither removal of the foetuses nor of the ovaries prevented increased retention of N in the presence of the placentae. The mechanism is not yet known.—D. Duncan.

BEATON, G. H., RYU, M. H. and MCHENRY, E. W. **Studies on the role of growth hormone in pregnancy.** *Endocrinology*, 1955, **57**, 748–754. [Dept. Pub. Health Nutrit., Univ. Toronto.]

In 3 experiments studies were made on female rats given a diet to appetite with 20 per cent. casein and 20 per cent. maize oil; in a fourth experiment studies were made on rats given unlimited amounts of fox chow and water. When growth hormone was injected intraperitoneally into non-pregnant female rats there were significant decreases in liver alanine-glutamic transaminase and *d*-aminoacid oxidase, resembling alterations found in pregnant rats (Abst. 2443, Vol. 25). The hormone treatment did not produce significant changes in bodyweight, liver weight or packed cell volume, but the trends were similar to those of pregnancy. In the second experiment when oestrogen, progesterone and growth hormone were administered simultaneously to non-pregnant rats many of the biological changes typical of pregnancy were produced, but when, in the third experiment, crude pituitary powder was administered metabolic changes characteristic of pregnancy were not produced. In the fourth experiment hypophysectomy of pregnant rats on the twelfth day of gestation did not terminate pregnancy but led to a decrease in liver weight, alanine-glutamic transaminase, packed cell volume and blood amino N. It is suggested that growth hormone may be responsible for some of the metabolic changes which occur in the rat during pregnancy.—G. F. Garton.

TUCHMANN-DUPLESSIS, H. and MERCIER-PAROT, L. Hypophyse et développement prénatal. L'hormone somatotrope est-elle responsable du gigantisme foetal? [**The pituitary and prenatal development. Is the growth hormone responsible for foetal gigantism?**] *Presse méd.*, 1955, **63**, 1831–1834. [Lab. Embryol., Fac. Méd., Paris.]

Growth hormone (Choay), hereafter denoted by STH, 10 I.U. daily, was injected into rats [number not stated] from the third to the sixth day after mating. Some were allowed to go to term; from others the foetuses were removed on the 20th day.

Glycosuria was not found in treated rats. Parturition was delayed for from 3 to 6 days and was slow and painful. All the offspring were born dead and they were mostly very large, weighing up to 7 g.; the normal birthweight for the rats used was 4·5 to 5 g.

In contrast, 20-day foetuses were always below normal weight, the average for 68 being 1·22 g. compared with 2·18 g. for those from untreated rats, a diminution of [over] 40 per cent. They appeared normal but resembled 18-day or 19-day foetuses from untreated rats, and this was confirmed by sections of head and body (photographs reproduced). That is, the increased size of the foetuses of treated rats was due merely to the extra length of gestation, in agreement with the results of Frazer *et al.* (Title 2240, Vol. 19).

It was thought possible that STH increased protein anabolism in the mother and thereby deprived the foetus of nutrients; but when other rats were treated from the fourth, fifth, sixth, seventh or eighth day till the sixteenth it was found that foetal growth was not significantly retarded unless STH was injected before the fifth day after mating.

Two groups each of 10 rats had their pituitaries removed on the twelfth day; one group were allowed to go to term and the foetuses were removed from the others on the 20th day. A third group had sham operations and had their food restricted to that taken by the hypophysectomised rats. Twenty-day foetuses from hypophysectomised rats appeared normal and did not differ in weight from those from sham-operated rats, in agreement with the results of Campbell *et al.* (Abst. 3343, Vol. 23). Of rats allowed to go to term, some produced live offspring of normal weight, others gave birth with difficulty from 2 to 4 days late. The mean weight of 24-day foetuses was 5·6 g., 1 g. more than that of untreated rats.

The possibility that foetal growth is controlled by the pituitary of the foetus is then discussed.

Parry, H. B. and Taylor, W. H. **Renal function in sheep during normal and toxaemic pregnancies.** *J. Physiol.*, 1956, **131,** 383–392. [Nuffield Inst. Med. Res., Univ. Oxford.]

Studies were of 10 normal ewes, of 7 in which toxaemia was spontaneous and 5 in which it had been induced experimentally by the senior author's method of subjecting well fed and overweight ewes late in pregnancy to a sudden reduction of feed intake (Title 3133, Vol. 25). Renal function was examined by estimation of levels of urea and creatinine in plasma and urine and by measurements of blood pressure and of urea, creatinine and *p*-aminohippurate clearances. Anatomical and histological examinations also were made of kidneys.

The impairment of renal function was similar in the 2 groups of toxaemic ewes and was considerable in extent, but could not be related to blood pressure or dehydration. The condition is briefly compared with that found in women; the main difference is the absence of hypertension in the ewes.—D. Harvey.

De Luca, R., Cutroneo, A. and Macchia, A. Il quadro proteinemico nelle nutrici. [**Blood proteins in nursing women.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 377–380. [Ist. Clin. Pediat., Univ. Messina.]

Total protein, fat and lactose were estimated in the milk and an electrophoretic analysis was made of the blood serum proteins of 25 lactating women with babies aged from 11 days to 12 months. In 10 the composition of the milk was normal, and the electrophoretic pattern of the serum proteins was normal also. In 15 total protein and lactose were less than normal. In their serum there was increase of α_2-globulin and in 5 of α_1-globulin also; in 1, γ-globulin was increased. Low lactose concentration of the milk is attributed to retention of milk in the mammary gland caused by incomplete emptying or by too great length of the intervals between feeds.—E. M. Hume.

Black, A. L. and Kleiber, M. **The recovery of norleucine from casein after administering norleucine-3-C^{14} to intact cows.** *J. Amer. Chem. Soc.*, 1955, **77,** 6082–6083. [Sch. Vet. Med., Univ. California, Davis.]

Labelled DL-*nor*leucine, 3·6 and 3·3 mC., was injected intravenously into 2 cows. From the first, 30 per cent. of the ^{14}C was recovered in milk over 46 hr., about a third of it in the casein. In a sample of casein separated from milk drawn 3 hr. after the injection the essential amino acids, including leucine and *iso*leucine, were not significantly radio-active; the non-essential acids were rich in ^{14}C. Paper chromatography of a fraction eluted from a Dowex-50 column revealed a small amount of radio-active *nor*leucine. A sample of casein from milk collected 10 hr. after injection was found to contain *nor*leucine. Preliminary analysis of milk collected from the second animal 3 hr. after injection confirmed the finding, and experiments *in vitro* excluded the possibility of the *nor*leucine having been adsorbed by the casein.

It is concluded that *nor*leucine was incorporated in casein by peptide linkage.—D. Harvey.

DAUWALDER, M. Untersuchungen über den Calciumstoffwechsel mit radioaktivem Calcium bei der Milchziege. [**Studies of calcium metabolism with radio-active calcium in the milk goat.**] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, **65,** 359–380. [Inst. Tierzucht Hyg., Univ. Berne.]

The subject was a 5-year-old lactating goat which was given in successive experiments $^{45}CaCl_2$ by mouth and ^{45}Ca as lactobionate intravenously. Milk, blood and urine were taken for estimation of ^{45}Ca.

In each of 2 experiments the goat received about 0·09 mC. ^{45}Ca every second day for 10 doses. Four hours after the first dose the radio-activity in 1 g. urine was 5 times and that in milk 40 to 50 times that in serum. In the 2 experiments together the mean urine activity on the days on which ^{45}Ca was given was twice and the mean milk activity 3 or 4 times that in serum ; on intermediate days the corresponding relative values were 3 times and 5 times those in serum. In the second experiment activity was not found in the serum more than 13 days after the last dose was given, but ^{45}Ca appeared in the milk for another 10 days.

In the other 2 experiments labelled lactobionate was injected every second day for 10 and for 8 doses, each again of 0·09 mC. At the beginning of each experiment blood samples were taken 1, 10 and 30 min. and 3 hr. after the injection. The serum radio-activity after 10 min. was little more than half the initial value, after 30 min. a third and after 3 hr. a tenth or less. The activity of milk was small until the following day, and then it varied much as in the experiments with $^{45}CaCl_2$ given by mouth. In the first of these experiments the serum radio-activity disappeared within 3 days after the last injection, urine activity in 10 days and milk activity in about 14 days.

After the last experiment the goat was killed. Tissues were fixed and ashed and the distribution of ^{45}Ca in the ash was studied. The greatest activity per g. was in the skeleton, and especially in the callus around a fracture sustained during the experiment. The most active soft tissue was the udder and then the large intestine and lungs ; no activity was found in the small intestine, spleen, lymph nodes, adrenals or hair.

The goat's milk was given to 7 guineapigs, which were also killed at the end of the experiment or examined when they died ; 3 died of a diplococcus infection. Four were born during the time when the mothers were receiving labelled milk, and they had at birth a higher concentration of ^{45}Ca in the skeleton than the adults.—D. Duncan.

MANSON, W. **Acid-soluble nucleotides of lactating mammary gland.** *Biochim. biophys. Acta*, 1956, **19,** 398–399. [Dept. Biochem., Hannah Dairy Res. Inst., Ayr.]

Perchloric acid extracts of mammary tissue from a goat after 14 days of lactation and a cow after 200 days were analysed by anion-exchange chromatography for nucleotides. There was little qualitative differences between the 2 sources, although quantitatively there were wide variations. Tissue from the goat and cow contained 25 and 12 μmol. uridine diphosphate acetylglucosamine and 40 and 15 μmol. uridine diphosphate glucose per 100 g. The significance of the high concentrations of the latter in relation to synthesis of lactose is being investigated. Other nucleotides found were the mono- and diphosphates of uridine, cytidine and adenosine, uridine triphosphate, adenosine triphosphate, guanylic acid and di- and triphosphopyridine nucleotides.—A. Hepburn.

REPRODUCTION: BIRDS

3473

PIANA, G. P-Ossipropiofenone, ormoni gonadotropi preipofisari, ACTH e produzione di uova. (Ricerche sperimentali e considerazioni.) [***p*-Oxypropiophenone, anterior pituitary gonadotropic hormones, ACTH and egg production : experimental study and discussion.**] *Riv. Zootec.*, 1956, **29,** 15–26.

Of 3 groups, comprising in all 75 White Leghorn hens, the first group was untreated ; the second received by mouth *p*-oxypropiophenone, 62 mg. per head daily for 10 days and then 125 mg. per head daily for 30 days ; the third received twice these amounts.

In 6 months before treatment began egg production had been almost the same in all 3 groups, with totals of 747, 750 and 753 eggs. During the period of treatment the treated groups produced, respectively, 21·8 and 16·7 per cent. more eggs than the untreated birds and in 20 days after the end of treatment, 23·8 and 21·6 per cent. more. Oxygen consumption, estimated before and towards the end of treatment, was slightly augmented in treated birds.

At the end, tissues were studied histologically. In the second group the anterior pituitary showed enlarged cells, often elongated and cylindrical, with clear, finely granular protoplasm, indicative of great activity. In the third group the cells were not enlarged, but the protoplasm was again clear and finely granular and in addition there appeared to be cellular hyperplasia, shown by more numerous

nuclei. The thyroids of treated birds showed only slight evidence of increased activity. The ovaries and oviducts showed the effects of stimulation.

A second similar experiment gave similar results, but 500 mg. *p*-oxypropiophenone daily for 20 days was less effective than the smaller amounts. Anterior pituitary gonadotropic hormone A had a slight stimulatory effect, placental gonadotropic hormone a larger one, but adrenocorticotropic hormone had none.

The possible mode of action of *p*-oxypropiophenone is discussed.—D. Duncan.

McCallion, D. J. and Wong, W. T. **A study of the localization and distribution of glycogen in early stages of the chick embryo.** *Canad. J. Zool.*, 1956, **34,** 63–67. [Dept. Biol., Acadia Univ., Wolfville, N.S.]

Glycogen was measured histochemically in chick embryos in each of 3 stages of development, the definitive streak, the head process stage and the head fold stage. In general the content was greatest in the first and least in the third of these stages. The concentration of glycogen in the ectoderm was greatest at the first and fell at the other 2 stages; there was little or none in the mesoderm and endoderm at any stage.

3475

Ravaioli, L. Frazionamento elettroforetico de liquido allantoideo di embrione di pollo. [**Electrophoretic fractionation of allantoic fluid of the chick embryo.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18,** 1119–1128. French, English and German summaries.

For each analysis was used the allantoic fluid from 5 eggs incubated at 39° C. and relative humidity 85 per cent. Eggs were taken on the ninth, tenth, eleventh, twelfth and thirteenth days of incubation. Total and protein N were estimated and the fluid was concentrated by dialysis before paper electrophoresis.

Protein N increased from 0·91 to 6·53 [? mg.] per cent. and total N from 0·237 to 1·324 [? mg.] per ml. during the 5 days of study, but each showed a slight decline on the eleventh day, probably because of an increase in fluid volume. On electrophoresis the protein was divided into 3 distinct bands, the first of which migrated at the same rate as chicken serum albumin, the other 2 somewhat more slowly. On the twelfth and thirteenth days the velocity of the first band decreased so that it tended to merge with the second.—D. Duncan.

3476

Johnston, P. M. and Comar, C. L. **Distribution and contribution of calcium from the albumin, yolk and shell to the developing chick embryo.** *Amer. J. Physiol.*, 1955, **183,** 365–370. [Univ. Tennessee-Atomic Energy Commission Agric. Res. Programme, Oak Ridge.]

Three experiments were made on 72, 72 and 60 fertile eggs of mixed breeds which, after allowing for temperature equilibration, were injected with 25 μC. of ^{45}Ca as chloride. The eggs were then incubated under standard conditions; at 24-hr. intervals 4 or more eggs were selected at random and samples of yolk, albumin, blood and extra-embryonic fluid were taken for measurement of radio-activity and for chemical analysis. Beginning with the third day, 2 or more embryos were taken for ^{45}Ca and total Ca estimation. After hatching, daily blood samples were taken for 8 more days and analyses were made of both the blood and the chick.

The embryonic ash increased logarithmically between 3 and 9 days and between 9 and 19 days. The Ca of the embryo increased logarithmically between 3 and 9 days, between 9 and 15 days and between 15 and 21 days. The correlation is presented between the Ca content of the ash and the degree of ossification. The embryonic ^{45}Ca derived from the albumin ranged from 0·00076 per cent. of the amount injected at 3 days to 82 per cent. at 20 days. Specific activity values indicated that up to about 10 days most of the embryonic Ca was derived from the yolk. After 10 days the shell began to contribute Ca to the embryo.

G. F. Garton.

3477

Machlin, L. J., Struglia, L. and Pearson, P. B. **Metabolism of methionine and cysteine sulfur in the developing chick embryo.** *Arch. Biochem. Biophys.*, 1955, **59,** 326–331. [Animal and Poultry Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

After incubation for 24 hr., cysteine or methionine labelled with ^{35}S was injected into the whites of eggs. The percentage recovery of ^{35}S in the newly hatched chick was in taurine 10·5, sulphate 11·9, methionine 1·3 and cystine 49·3 from radio-active cysteine and 9·1, 10·1, 34·8 and 43·2 from radio-active methionine. Most of the sulphate was bound to protein. The sulphate S content of whole egg increased from 2·9 mg. at the beginning of incubation to 7·1 mg. in the newly hatched chick. The embryo always contained less than the remainder of the egg up to 18 days' incubation.

A. Hepburn.

SENESCENCE

3478

Orchard, N. P. **Blood changes in the aged.** *Geriatrics*, 1955, **10,** 459–468. [Dartford, England.]

Samples of blood from the cubital vein and of bone marrow from the iliac crest were taken from 150 patients whose ages ranged from 65 to 99 years

and who were living in an institution. They were chronically sick, but not with diseases known to affect haemopoiesis. The findings are tabulated separately for age and sex in 2 decades from 65 years and for over 85 years; in these groups there were 22, 26 and 10 men and 28, 38 and 26 women. The mean values for blood with standard error were, for all the men, red cell count 5·04 ± 0·08 million per c. mm.; Hb 15·46 ± 0·23 g. per 100 ml.; mean corpuscular Hb concentration 34·83 ± 0·23 per cent.; packed cell volume 44·62 ± 0·62 per cent.; mean corpuscular volume 88·49 ± 0·57 c. μ. [tabulated 88·15 c. μ.]; mean corpuscular diameter 7·58 ± 0·03 μ.; white cell count 7205 ± 279 per c. mm.; red sedimentation rate (Wintrobe) 17·84 ± 1·21 mm. in 1 hr. Corresponding averages for all the women were 4·82 ± 0·05; 14·58 ± 0·19; 34·49 ± 0·22; 42·29 ± 0·45; 87·94 ± 0·52; 7·50 ± 0·02; 6494 ± 185; 17·51 ± 1·10. No gross change was found in the bone marrow.

The findings are discussed and compared, as far as possible, with those of other workers. The main conclusions are that in both sexes there is an increase in red cell diameter in old age; that a sex difference exists in packed cell volume, which is significantly less in women than in men; and that anaemia is not a physiological change accompanying ageing.—D. Harvey.

3479

LORENZINI, R. and INNOCENTI, E. L'indagine elettroforetica delle lipoproteine del siero nella pratica clinica. Il quadro lipoproteico dell'età presenile e senile in rapporto con la presenza di gerontoxon. [**Electrophoretic study of serum lipoproteins in clinical practice. The lipoprotein picture in pre-senility and senility in relation to the presence of gerontoxon.**] *Acta gerontol.*, 1955, **5**, 291–304. [Ist. Clin. Med. Gen., Univ. Modena.] French and English summaries.

Electrophoretic studies were made of serum from 55 subjects of both sexes aged from 45 to 86 years. The subjects were divided into 2 groups, those without signs of localised lipoidosis, and those who although clinically normal had *arcus senilis* (gerontoxon) or xanthelasma. The first group contained 12 men and 10 women, the second 21 men and 12 women. The results are shown in tables and diagrams.

The normal subjects of the first group showed higher levels of γ-globulin and sometimes of β-globulin than younger subjects, but the total protein was normal because albumin was low. There was some increase in the lipid fraction of medium velocity in lipidograms. The subjects with *arcus senilis* or xanthelasma showed similar behaviour of the serum proteins. The lipid fractions of medium and low velocity were increased, that of high velocity tended to be reduced. It is concluded that in these subjects the changes characteristic of advancing age were exaggerated.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

3480

SMITH, J. M. and DUBOS, R. J. **The behavior of virulent and avirulent staphylococci in the tissues of normal mice.**
The effect of nutritional disturbances on the susceptibility of mice to staphylococcal infections.
The effect of dinitrophenol and thyroxin on the susceptibility of mice to staphylococcal infections. *J. Exp. Med.*, 1956, **103**, 87–108; 109–118; 119–126. [Labs., Rockefeller Inst.]

(a) Not nutritional, but the strains of staphylococci used in the nutritional experiments are described.

(b) Despite wide individual variations in susceptibility to an infective dose of staphylococci, mice fasted for 36 or 48 hr. before infection were much more susceptible than those not fasted. The livers of mice fasted before infection gave about 10 times as many bacterial colonies in cultures as those of fed mice on any day after infection. Glucose given in the drinking water during the fasting period consistently increased the effect of fasting, so did Na salts of butyric, glutaric and pyruvic acids, but lactate seemed to have some protective value, in 1 per cent. solution. Glucose had no effect when the mice were not fasted.

Mice fed on a low-protein diet with 4 per cent. skimmed milk powder or given a normal diet in restricted amount were retarded in growth, but there was no significant effect on their resistance to staphylococcal infection.

(c) When mice were given enough dinitrophenol or thyroid extract in their drinking water to retard or prevent growth their susceptibility to staphylococcal infection was greatly increased. Even when the organism injected was unable to cause death in mice on normal diet, mice given dinitrophenol or thyroid died. This agrees with the effect of these substances on susceptibility to experimental tuberculosis (Abst. 3987, Vol. 25).

SCHNEIDER, H. A. and ZINDER, N. D. **Nutrition of the host and natural resistance to infection.**

5. An improved assay employing genetic markers in the double strain inoculation test. *J. Exp. Med.*, 1956, **103,** 207–223. [Rockefeller Inst. Med. Res.]

For part 4 see Abst. 2487, Vol. 19.

5. Weanling mice were fed either on a synthetic diet, diet 191, or on whole wheat and whole dried milk; the latter diet produces the greater resistance to infection with *Salmonella typhimurium*, as described earlier (Abst. 3397, Vol. 18). The double strain inoculation test with an avirulent followed by a virulent strain was also described in that paper, but has now been modified. Weanling mice receive diet 191 for 3 weeks and are then moved to individual cages in the infection room and given either diet 191 or the wheat diet. After 4 days they receive an intraperitoneal inoculation of 10^3 viable cells of avirulent RIA strain of *S. typhimurium*, followed 2 days later by 10^3 viable cells of virulent, xylose-fermenting strain SR-11. Two days after the second injection the mice are killed and the salmonellae in their spleens are counted on eosin and methylene blue agar containing xylose. The counts of virulent bacteria per spleen are consistently low in mice on the wheat diet. The effect of the diet was detected 24 hr. after a change in either direction. A group of 5 mice is enough for each test.—D. Duncan.

3482

TAYLOR, D. J. and GREENBERG, J. **Hyperactivity of metachloridine against *Plasmodium gallinaceum* in chicks maintained on a purified diet.** *Proc. Soc. Exp. Biol. Med.*, 1955, **90,** 551–554. [Nat. Microbiol. Inst. Lab. Trop. Dis., Nat. Insts. Health, Bethesda, Md.]

For a description of the technique and purified diet see Greenberg *et al.*, *Amer. J. Hyg.*, 1954, **60,** 99 and reference in Abst. 1651, Vol. 23. In this series week-old chicks on stock diet and the C-2 purified diet were given intravenously 16×10^6 erythrocytes containing sporozoites of *Plasmodium gallinaceum* and 9 antimalarial drugs were tested. With 7 of them diet had no effect; sulphadiazine and metachloridine were 16 times as active when the chicks had C-2 diet. Addition of 41 per cent. soya bean meal to this diet completely annulled its effect. The substance responsible was not in the fat or soluble protein or acid extract.; it was soluble or labile in alkali.—I. Leitch.

3483

BADIALI, C., LA PLACA, M. and ROMANO, G. C. Ulteriori ricerche sull'influenza della vitamina C sullo sviluppo del *B. di Koch.* [**Further researches on the influence of ascorbic acid on the growth of *Mycobacterium tuberculosis*.**] *Boll. Ist. sieroterap. milan.*, 1955, **34,** 530–535. [Ist. Igiene, Univ. Bologna.] English summary.

It had previously been shown that when ascorbic acid had been added to the culture medium of Dubos, *Mycobacterium tuberculosis* survived as long as ascorbic acid was still present in the medium but died some 3 days after the vitamin could no longer be detected (*Nuovi Ann. Ig. Microbiol.*, 1954, **5,** 217).

In the present investigation the culture medium was that of Dubos or a physiological solution glycerinated to 5 per cent. Ascorbic acid was added, 1 mg. per ml., and the concentration in the medium was estimated by indophenol titration. Test tubes containing the medium with and without addition of ascorbic acid were incubated at 37° C. for 10 days, by which time ascorbic acid could no longer be detected. They were then inoculated with *Mycobacterium tuberculosis*. At intervals from 2 to 360 hr. later, the contents of a tube were centrifuged; the sediment was washed and half of it was inoculated at *p*H 6·6 into normal culture medium and half subcutaneously into a living guineapig. With the glycerinated medium only the test on guineapigs was made.

In the tests without ascorbic acid a nodule developed in the guineapig and progressed to ulceration. In the tests with ascorbic acid the reaction was progressively less the longer the organisms had been in contact with the medium which had formerly contained ascorbic acid.

In sub-culture the organisms no longer grew in Dubos medium after 20 hours' contact, or in glycerinated medium after 120 hours' contact.

It is concluded that the bactericidal action was due to one or more stable products of the autoxidation of ascorbic acid.—E. M. Hume.

KOSER, S. A. and THOMAS, J. L. **Amino acid requirements of oral lactobacilli.** *J. Infect. Dis.*, 1955, **97,** 287–298. [Walter G. Zoller Mem. Dent. Clin., Univ. Chicago, Ill.]

At least 8 to 10 amino acids, and often more, were essential for growth of 28 strains of oral lactobacilli. Other amino acids stimulated growth, which was often otherwise slow. Arginine, cysteine or cystine, glutamic acid, leucine, phenylalanine, tryptophan; tyrosine and valine were essential for most lactobacilli. Histidine and proline were essential for *Lactobacillus acidophilus*. *Iso*leucine was essential for a strain of *L. fermenti* and stimulated growth of all other lactobacilli.

L. acidophilus was more exacting in amino acid requirements than *L. plantarus* and *L. casei*. *L. fermenti*, in contrast to *L. casei*, usually required threonine and was stimulated by alanine in the presence of vitamin B_6. The amino acid requirements of oral lactobacilli were similar to those of cultures from other sources.—A. Hepburn.

WILLINGALE, J. M. and BRIGGS, C. A. E. **The normal intestinal flora of the pig. 2. Quantitative bacteriological studies.** *J. Appl. Bacteriol.*, 1955, **18**, 284–293. [Nat. Inst. Res. Dairying, Univ. Reading.]

For part 1 see Abst. 5017, Vol. 24.

Bacterial counts of faeces and caecal contents were made by inoculation of serial 1 : 10 dilutions into liquid media in quintuplicate. After 3 days of incubation the numbers of bacteria were assessed from probability tables. The media were reinforced clostridial medium, tomato glucose broth and MacConkey's broth. Faecal samples were obtained freshly from live pigs and faecal and caecal samples from pigs at slaughter.

From a large number of counts were estimated the day-to-day variation in faecal counts of individual pigs on one ration over 4 weeks, variations between different individuals on the same ration, and the effect of different rations. The normal range of total viable counts under all these conditions was $1{\cdot}0 \times 10^8$ to $9{\cdot}9 \times 10^9$ per g. Faecal and caecal counts of individual pigs were very similar when corrections were made for percentage dry matter.

The predominant bacteria were streptococci and lactobacilli, with smaller numbers of coliform bacteria, micrococci, bacilli, *Pseudomonas* spp., and moulds.—J. C. Appleby.

RICHTER-OTTO, W. Untersuchungen der Kotflora bei mit Antibioticis gefütterten Ratten. **[Faecal flora of rats fed with antibiotics.]** *Arch. Tierernährung*, 1955, **5**, 257–287. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

Four groups, each of 2 male and 9 female rats with an average initial weight of 55 g., were the parent generation. They received to appetite a mixed ration containing no antibiotic, or 25 mg. penicillin, streptomycin or aureomycin per kg. ration. Observations were made on these rats and on 3 filial generations.

There was no statistically significant effect of the antibiotics on growth or on reproduction, with the exception that the litters of F_3 rats in the penicillin group were larger than the litters of controls, with slight significance. Bacteriological examination of the faeces showed that aureomycin and penicillin tended to reduce the counts of all bacteria except coliforms, which were increased, as were fungi. Streptomycin inhibited coliforms and increased enterococci. The results are given in full in tables.—D. Duncan.

SAMMONS, H. G., VAUGHAN, D. J. and FRAZER, A. C. **Synthesis of long-chain fats by bacteria isolated from human faeces.** *Nature*, 1956, **177**, 237. [Dept. Pharmacol., Univ. Birmingham.]

An organism which appeared to resemble *Streptococcus faecalis* was isolated from the stool of a patient with steatorrhoea under treatment with folic acid. This organism synthesised fat in peptone glucose medium, particularly in the presence of folic acid, where it amounted to 200 mg. in 10 ml. medium in 4 days. The fat was collected from the surface of the culture, and some of its properties are given.—J. C. Appleby.
